

# Ulbasca

Ulbasca's terrain is flat and rocky, with little vegetation at all. The moon's mineral survey indicated a collection of the most common elements in the galaxy, with nothing of any real value. The atmosphere contains enough oxygen to support a variety of lifeforms, including Humans, but it also contains traces of gases poisonous to most of the races in the known galaxy. Breath masks are required if a being wants to spend more than a couple of hours on the surface. Small mountains and rocky canyons break the monotonous flatness of most of the surface. These canyons support the few lifeforms native to this place.

The strangest feature of this moon is its orbit around Genarius. Ulbasca marks a path through the heavens that keeps it constantly in the light of Cularin's suns. Because the dark side is bathed by light from Genarius itself, it is never truly night there at all. The darkest time is a short twilight period when one side faces away from the suns; this lasts for about nine hours.

Small reptiles existing on sulfurous plants predominate in the ecology of this world. The lizards come in various sizes and fill all ecological niches. These reptiles are, for the most part, like the snakes of other worlds, but some have short legs they use while climbing the rocky canyons. Larger snakes can be as long as 40 meters and can swallow a Human whole.
