The Seeker is built on the Scout/Courier design, converting the two small staterooms and 116 m³ of the cargo hold into a special 172 m³ ore bay, and the addition of a 150-Mj TL-15 mining laser turret to the socket already installed, adding MCr0.86 to the price and 57 tonnes to its mass. (Turret Loc: 10; Arc: 1,2,3; 4.2 MW, 1 Crew)

Jayhawk-Class Far Trader

General Data

Displacement: 200 tons
Length: 43 meters
Price: MCr57.21
Configuration: Wedge SL
Mass (Loaded/Empty): 1918.38/1093.78
Hull Armor: 10
Volume: 2800m³
Target Size: S
Tech Level: 12

Engineering Data

Power Plant: 148 MW Fusion Power Plant (49 MW/hit), 1 year duration (0.7705 MW excess power)
Jump Performance: 2 (420 m³ fuel)
G-Rating: 1G (100 MW/G), Contra-Grav lifters (20 MW)
G-Turns: 48 (81.6 using jump fuel), 12.5 m³ each
Maint: 89

Electronics

Computer: 3×TL-12 Model St (0.4 MW ea.)
Commo: 30,000 km radio (1 hex, 1 MW), 1000 AU maser (∞; 0.6 MW)
Avionics: TL-10+ Avionics
Sensors: Passive EMS fixed array 30,000km (1 hex, 0.03 MW), Active EMS 3000 km (0 hexes; use long range for task difficulty in same hex; 8 MW)
Controls: Flight deck with 3×Workstation, 1 other workstation

Armament

2 turret hardpoint sockets fitted (Loc: 8,9; Arcs: 1,2,3)

Accommodations

Life Support: Extended (0.56 MW), Grav Compensators (3 G; 14 MW)
Crew: 5 (2×Maneuver, 1×Electronics, 1×Engineering, 1×Steward)
Crew Accommodations: 5×Small Stateroom (0.0005 MW ea.)
Passenger Accommodations: 10×Small Stateroom (0.0005 MW ea.)
Cargo: 743.8 m³, 2 large cargo hatches
Small Craft and Launch Facilities: Air raft with internal hangar (Minimal), 1 launch port
Air Locks: 2

Notes

Fuel purification machinery (1.53 MW), 24 hours to refine 1020 m³ (72.86 tons).

Moraine-Class Free Trader

General Data

Displacement: 200 tons
Length: 43 meters
Price: MCr46.47
Configuration: Wedge SL
Hull Armor: 10
Volume: 2800m³
Target Size: S
Tech Level: 10
Mass (Loaded/Empty): 1908.146/1074.746

Engineering Data

Power Plant: 156MW Fusion Power Plant (52 MW/hit), 1 year duration (17.967 MW power shortfall)
Jump Performance: 1 (280 m³ fuel)
G-Rating: 1G (100 MW/G), Contra-Grav lifters (40 MW)
G-Turns: 56 (78.4 using jump fuel), 12.5 m³ fuel each
Maint: 89

Electronics

Computer: 3×TL-10 Model St (0.3 MW ea.)
Commo: 30,000km radio (1 hex; 1 MW), 1000AU maser (∞; 0.6 MW)
Avionics: TL-10+ Avionics
Sensors: Passive EMS fixed array 30,000km (1 hex; 0.06 MW), Active EMS 300km (0 hexes; use extreme range for task difficulty in same hex; 15 MW)
Controls: Flight deck with 3×Workstation, plus 2 other workstations

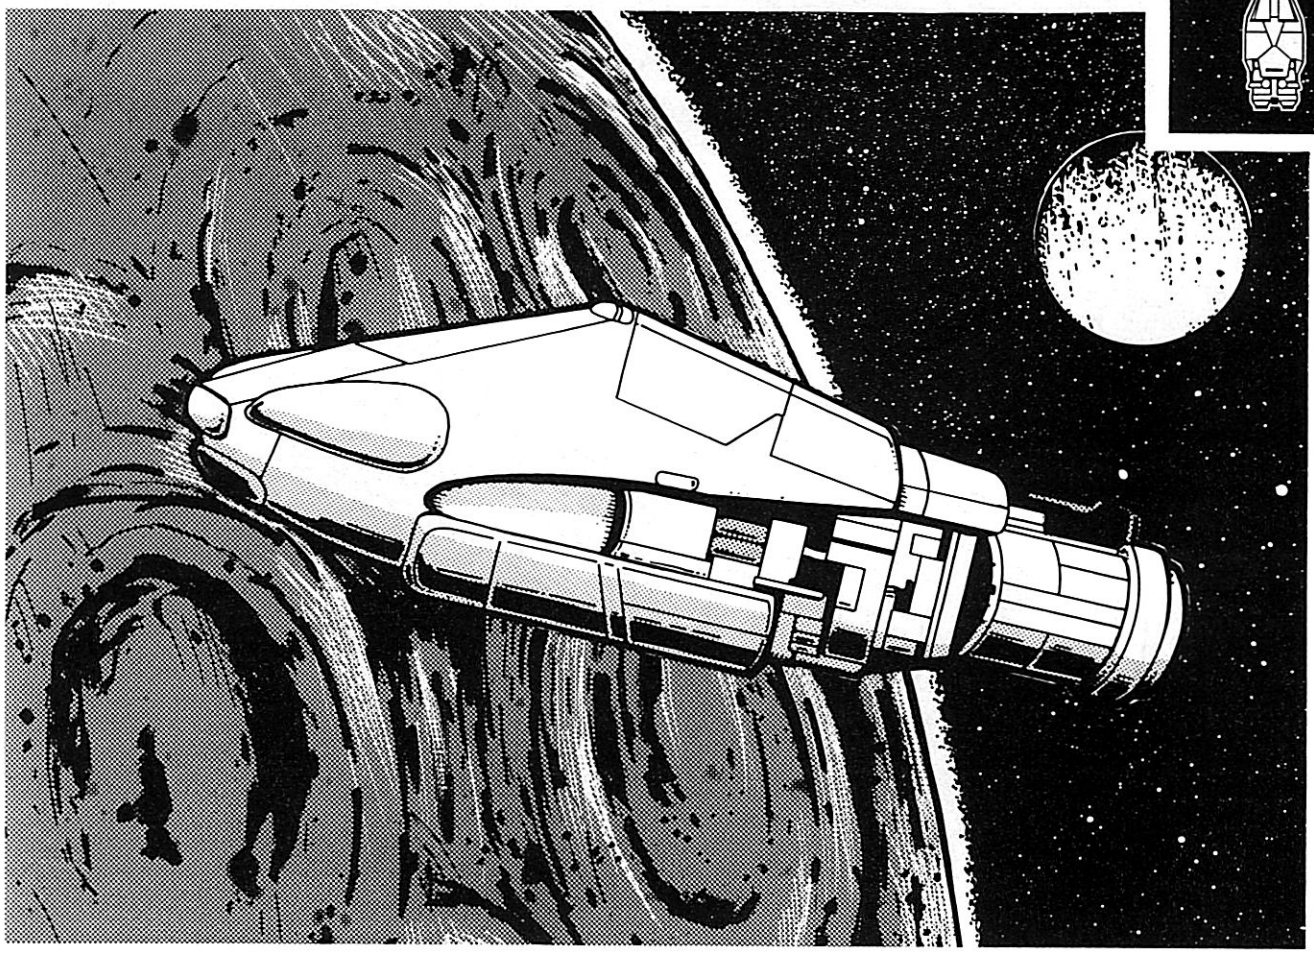
Armament

2 turret hardpoint sockets fitted (Loc: 16/17, 18/19; Arcs: All)

Accommodations

Life Support: Extended (0.56 MW), Gravitic Compensators (1G; 14 MW)
Crew: 6 (2×Maneuver, 1×Electronics, 2×Engineering, 1×Steward)
Crew Accommodations: 6×Small Stateroom (0.0005 MW ea.)
Passenger Accommodations: 8×Small Stateroom (0.0005 MW ea.), 8×Low Berth (0.001 MW ea.)
Cargo: 764.8 m³, 2 large cargo hatches
Air Locks: 2

Notes



The *Moraine* is the TL-10 version of the more popular and useful *Beowulf*-class. The *Moraine*'s systems consume 174 MW of power, meaning that it cannot operate them all at once with its 156 MW plant. In space, the contra-grav drive is shut down to conserve power. When taking off from a planet, the *Moraine* cannot power its G-compensators, and thus all crew and passengers must be strapped in for this evolution.

Fuel purification machinery (1.53 MW), 30.8 hours to refine 980 m³ (70 tons)

Lord Baltimore-Class Yacht

General Data

Displacement: 200 tons
Length: 51 meters
Price: MCr84.8
Configuration: Needle USL
Mass (Loaded/Empty): 1502.83/1207.44
Hull Armor: 42
Volume: 2800m³
Target Size: S
Tech Level: 15

Engineering Data

Power Plant: 456MW Fusion Power Plant (228 MW/hit), 1 year duration (0.2275 MW excess power)
Jump Performance: 4 (700 m³ fuel)
G-Rating: 4G (100 MW/G), Contra-Grav lifters (20 MW)
G-Turns: 32 (88 using jump fuel), 12.5 m³ of fuel each
Maint: 48

Electronics

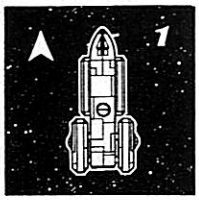
Computer: 3×TL-15 Model St (0.55 MW ea.)
Commo: 30,000km radio (1 hex; 1 MW), 1000 AU maser (∞; 0.6 MW)
Avionics: TL-10+ Avionics
Sensors: Passive EMS folding array 150,000km (5 hexes; 0.15 MW), Active EMS 300,000km (10 hexes; 15 MW)
Controls: Flight deck with 3×Workstation, plus 3 other workstations

Armament

1 turret hardpoint socket fitted. (Loc: 10; Arcs: All)

Accommodations

Life Support: Extended (0.56 MW), Gravitic Compensators (6G; 14 MW)
Crew: 9 (2×Maneuver, 3×Engineering, 3×Small Craft Flight Crew, 1×Command). Air raft pilot doubles as Steward
Crew Accommodations: 9×Small Stateroom (0.0005 MW ea.)
Passenger Accommodations: 10×Small Stateroom (0.0005 MW ea.), 1×Large Stateroom (0.001 MW) (owner's suite)
Cargo: 125 m³, one large cargo hatch
Small Craft and Launch Facilities: 10-ton skiff and internal hangar (Minimal), air raft with internal hangar (Minimal), one launch port each
Air Locks: 2



Notes

Fuel purification machinery (2.5 MW), 13.2 hours to refine 1100 m³ (78.57 tons)

Gazelle-Class Close Escort

General Data

Displacement: 280/400 tons
Length: 48.5 meters
Price: MCr224.65 (+MCr6.78 tanks)
Configuration: Wedge SL
Mass (Loaded/Empty): 4662.15/4155.53 with tanks
4154.87/3742.43 without tanks
Hull Armor: 62
Volume: 3920 m³/5600 m³
Target Size: S
Tech Level: 14

Engineering Data

Power Plant: 891 MW Fusion Power Plant (99 MW/hit), 1 year duration
Jump Performance: 3 with tanks attached (1120m³), 5 without (1260 m³)
G-Rating: 3G with tanks (200 MW/G), 5G without (150 MW/G), Contra-Grav lifters (30 MW)
G-Turns: 112, 25 m³ fuel each, with tanks attached; 77.6, 18.75 m³ each, without tanks
Maint: 143

Electronics

Computer: 3×TL-14 Model Fb (1 MW ea.)
Commo: 300,000km radio (10 hexes; 10 MW), 1000 AU maser (∞; 0.6 MW)
Avionics: TL-10+ Avionics
Sensors: Passive EMS folding array 150,000km (5 hexes; 0.15 MW), Active EMS 300,000km (10 hexes; 15 MW)
ECM/ECCM: EMS jammer (10 hexes; 30 MW), EM masking package (5.6 MW)
Controls: Bridge with 7×Bridge Workstation, plus 7 other workstations

Armament

Offensive: 2×TL-14 150-Mj Laser Turret (Loc: 16,17; Arcs: All; 4.2 MW, 1 crew ea.), 2×TL-14 300-Mj Laser Barbette (Loc: 4/5, 10; Arcs: 1,2,3; 8.3 MW, 1 crew ea.)
Master Fire Directors: 1 TL-14 (5 Diff Mod; Non-Msl; 10 hexes; 1.62 MW, 1 crew)

	Short	*Medium*	*Long*	*Extreme*
150-Mj Laser Turret	2:1/10-31	4:1/10-31	8:1/10-31	16:1/10-31
300-Mj Laser Barbette	10:1/14-43	20:1/14-43	40:1/8-26	80:1/4-13

Accommodations

Life Support: Extended (0.784 MW), Grav Compensators (5G; 19.6 MW)
Crew: 22 (7×Engineering, 1×Electronics, 2×Maneuver, 5×Gunnery, 1×Maintenance, 3×Small Craft Flight Crew, 3×Command)
Crew Accommodations: 2×Small Stateroom (0.0005 MW ea.), 8×Large Stateroom (0.001 MW ea.) (multiple-occupancy)
Cargo: 10.8 m³, one small cargo hatch
Small Craft and Launch Facilities: SL external grapple for 20-ton small craft
Air Locks: 3

Notes

As with many other small military designs, the *Gazelle* is very tight. Its 22 crewmembers share accommodations for 18, requiring some "hot bunking."

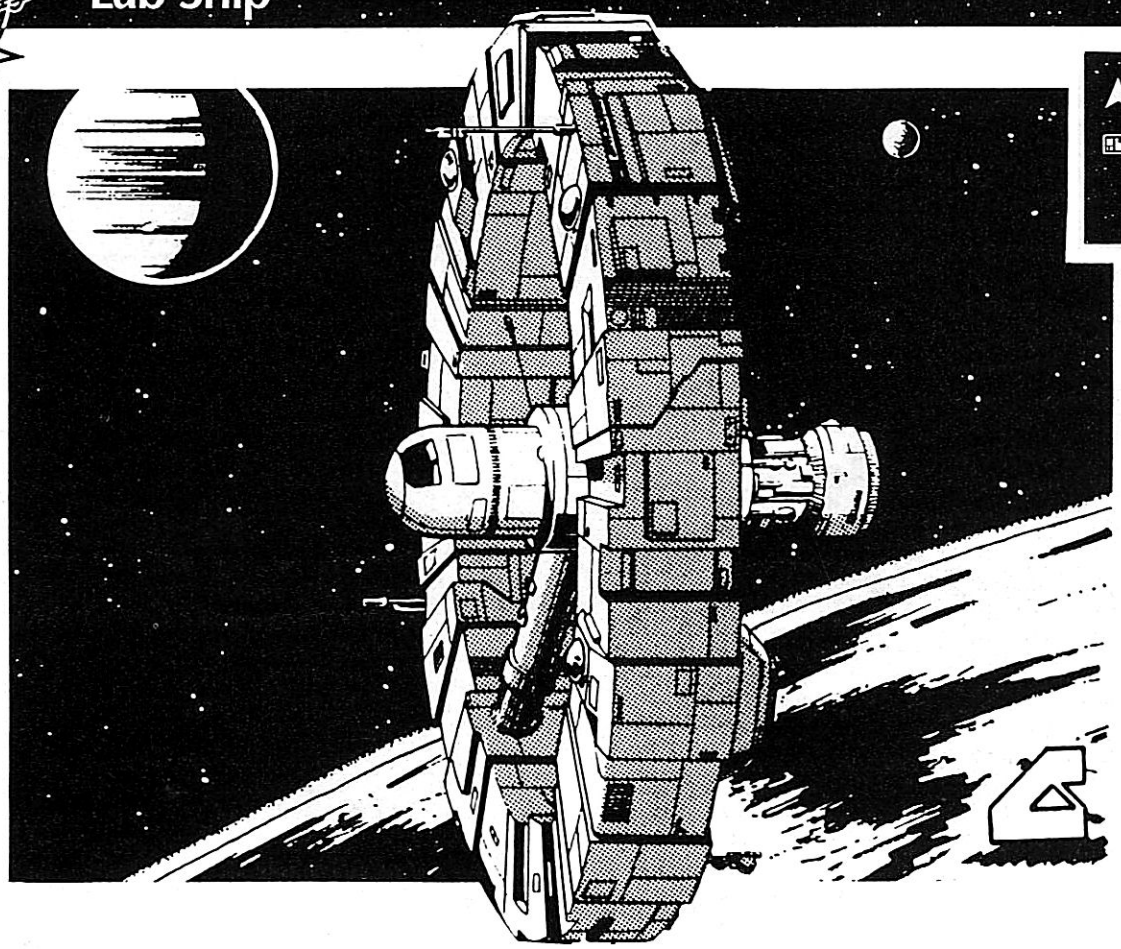
Without drop tanks, the *Gazelle* consumes 899.465 MW, requiring the contra-grav to be shut down, or the EMS jammer to function with a six-hex short range to make up the difference. With tanks attached, only 749.465 MW are needed.

Although it is streamlined with the drop tanks attached, the *Gazelle* only has contra-grav performance for 300 tons, not 400.

2800 m³ of fuel total (200 tons), 1345 (96 tons) carried in 2 50-ton drop tanks, 1455 (104 tons) internal. 1120 m³ fuel for jump 3 with tanks attached, 1260 m³ for jump 5 without tanks. Fuel purification machinery (7.6 MW), 11.05 hours to refine 2800 m³.

Drop tanks are armored to same level as ship, and equipped with EMM.

Damage tables below assume drop tanks are attached.



If small craft is not being carried, surface small craft hits are taken by the grapple.

Lab Ship

General Data

Displacement: 390/400 tons
Hull Armor: 10
Diameter: 76 meters
Volume: 5460/5600 m³
Price: MCr129.41
Target Size: S
Configuration: Open USL
Tech Level: 15
Mass (Loaded/Empty): 2032.38/1352.49

Engineering Data

Power Plant: 265.2 MW Fusion Power Plant (265.2 MW/hit), 1 year duration (0.355 MW excess power)
Jump Performance: 2 (840 m³ fuel)
G-Rating: 1 (200 MW/G), no contra-grav
G-Turns: 96 (129.6 using jump fuel), 25 m³ of fuel each
Maint: 74

Electronics

Computer: 3×TL-15 Mod Fb Computer (1.1 MW ea.)
Commo: 300,000km radio (10 hexes; 10 MW), 1000AU maser (∞; 0.6 MW)
Avionics: TL-10+ Avionics
Sensors: Passive EMS folding array 180,000km (6 hexes; 0.2 MW), Active EMS 300,000km (10 hexes; 15 MW), TL-15 Densitometer (0.4 MW), TL-14 Neutrino detector (0.01 MW)
Controls: Flight deck with 4×workstation, plus 11 other workstations

Armament

4 turret hardpoint sockets fitted. (Loc: 12-15; Arcs: All)

Accommodations

Life Support: Extended (1.092 MW), Gravitic Compensators (6G; 27.3 MW)
Crew: 17 (2×Maneuver, 1×Engineering, 1×Electronics, 2×Small Craft Flight Crew, 1×Command, 10×Science Personnel)
Crew Accommodations: 17×Small Stateroom (0.0005 MW ea.)
Cargo: 359.7 m³, one large cargo hatch
Small Craft and Launch Facilities: USL External Grapple for 10-ton skiff, Internal Hangar (Minimal) for Air Raft (one of the crew doubles as air raft pilot), one launch port for air raft
Air Locks: 4

Notes

The Lab Ship itself displaces 390 tons, and with its launch attached displaces 400. Its jump, maneuver, contra-grav drives, and controls are configured to work with the 400-ton figure.

Workstations are provided for all 10 scientists.

Fuel purification machinery (3.55 MW), 27.38 hours to refine 3240 m³ (231.4 tons).

Patrol Cruiser

General Data

Displacement: 400 tons
Length: 66 meters
Price: MCr197.5
Configuration: Needle AF
Mass (Loaded/Empty): 3545.28/2933.8
Hull Armor: 42
Volume: 5600 m³
Target Size: S
Tech Level: 15

Engineering Data

Power Plant: 886.5 MW Fusion Power Plant (295.5 MW/hit), 1 year duration (39.65 MW power shortfall)
Jump Performance: 3 (1120 m³)
G-Rating: 4G (200 MW/G), Contra-Grav lifters (40 MW)
G-Turns: 60 (104.8 using jump fuel), 25 m³ of fuel each
Maint: 106

Electronics

Computer: 3×TL-15 Mod Fb Computers (1.1 MW ea.)
Commo: 300,000km radio (10 hexes; 10 MW), 1000 AU maser (∞; 0.6 MW)
Avionics: TL-10+ Avionics
Sensors: Passive EMS folding array 180,000km (6 hexes; 0.2 MW), Active EMS 300,000km (10 hexes; 15 MW)
ECM/ECCM: EM Masking (5.6 MW)
Controls: Bridge with 7×bridge workstation, plus 5 other workstations

Armament

Offensive: 2×TL-15 150-Mj Laser Turret (Loc: 2,3; Arcs: 1,2,3,4; 4.2 MW, 1 crew ea.), 2×Missile Turret (Loc: 12,13; 2 ready Msls ea.; 0.15 MW; 1 crew ea.) (total of 4 ready Msls, plus 8 in cargo).
Master Fire Directors: 2 TL-15 (6 Diff Mod; Msl 10 hexes; 10 hexes; 1.71 MW, 1 crew ea.)

	Short	*Medium*	*Long*	*Extreme*
150-Mj Laser Turret	10:1/10-31	20:1/10-31	40:1/10-31	80:1/10-31

Accommodations

Life Support: Extended (1.12 MW), Gravitic Compensators (6 G; 28 MW)
Crew: 19 (2×Maneuver, 1×Electronics, 5×Engineer, 6×Gunnery, 3×Small Craft Flight Crew, 2×Command)
Crew Accommodations: 2×Small Stateroom (command crew; 0.0005 MW ea.), 5×Large Stateroom (multiple-occupancy; 0.001 MW ea.)
Cargo: 0 m³, plus storage for eight missiles, one large cargo hatch
Small Craft and Launch Facilities: 30-ton Ship's Boat with internal hangar (Minimal), and one launch port
Air Locks: 4

Notes

The Patrol Cruiser is a rather tight design. The 19 crewmembers share accommodations for 12, requiring "hot bunking" for the gunnery and engineering crew.

The cruiser's total power requirement is 926 MW, limiting it to only 3G performance when the contra-grav is engaged.

Fuel purification machinery (9.7 MW), 8.1 hours to refine 2620 m³ (187.14 tons).

Power Plant: 286 MW Fusion Power Plant (48 MW/hit), 1 year duration (0.04 MW excess power)
Jump Performance: 1(560 m³ fuel)
G-Rating: 1G (200 MW/G), Contra-Grav lifters (40 MW)
G-Turns: 60 (82.4 using jump fuel), 25 m³ of fuel each
Maint: 180

Electronics

Computer: 3×TL-12 Mod St Computer (0.4 MW ea.)
Commo: 30,000km radio (1 hex; 1MW), 1000 AU maser (∞; 0.6 MW)
Avionics: TL-10+ Avionics
Sensors: Passive EMS fixed array 60,000km (2 hexes; 0.06 MW), Active EMS 3000km (0 hexes; use long range for task difficulty in same hex; 8 MW)
Controls: Flight deck with 4×workstation, plus 3 other workstations

Armament

4 turret hardpoint sockets fitted (Loc: 2-5; Arcs: 1,2,3)

Accommodations

Life Support: Extended (1.092 MW), Gravitic Compensators (3G; 27.3 MW)
Crew: 9 (2×Maneuver, 1×Electronics, 3×Engineering, 2×Steward [double as Small Craft Flight Crew], 1×Command).
Crew Accommodations: 1×Small Stateroom (command; 0.0005 MW ea.), 4×Large Stateroom (double-occupancy; 0.001 MW ea.)
Passenger Accommodations: 13×Small Stateroom (0.0005 MW ea.), 13×Low Berth (0.001 MW ea.)
Cargo: 1306.5 m³, four large cargo hatches
Small Craft and Launch Facilities: 10-ton Skiff in AF External Grapple
Air Locks: 4

Notes

The ship itself displaces 390 tons; with its launch, it displaces 400. Jump, maneuver, and contra-grav drives are all configured to support the 400-ton figure.

Fuel purification machinery (6.18 MW), 12 hours to refine 2060 m³ (147.14 tons).

Donosev-Class Survey Ship

General Data

Displacement: 600 tons
Length: 44 meters
Price: MCr306.18
Configuration: Close Structure, USL
Mass (Loaded/Empty): 4076.99/2206.44
Hull Armor: 20
Volume: 8400 m³
Target Size: S
Tech Level: 15

Engineering Data

Power Plant: 705 MW Fusion Power Plant (235 MW/hit), 1 year duration (0.0035 MW excess power)
Jump Performance: 3 (1680 m³ fuel)
G-Rating: 2G (300 MW/G), no contra-gravity
G-Turns: 104 (148.8 using jump fuel), 37.5 m³ of fuel each
Maint: 112

Electronics

Computer: 3×TL-15 Mod Fb Computers (1.1 MW ea.)
Commo: 2×300,000km radio (10 hexes; 10 MW ea.), 2×1000 AU maser (∞; 0.6 MW ea.)
Avionics: TL-10+ Avionics
Sensors: 1×Passive EMS folding array 240,000km (8 hexes; 0.3 MW), 1×Passive EMS folding array 180,000km (6 hexes; 0.2 MW), 2×Active EMS 300,000km (10 hexes; 15 MW ea.), TL-15 Densitometer 0.4 MW), TL-14 Neutrino Sensor (0.01 MW)
Controls: Bridge with 6×Bridge Workstation, plus 4×Crew Workstation

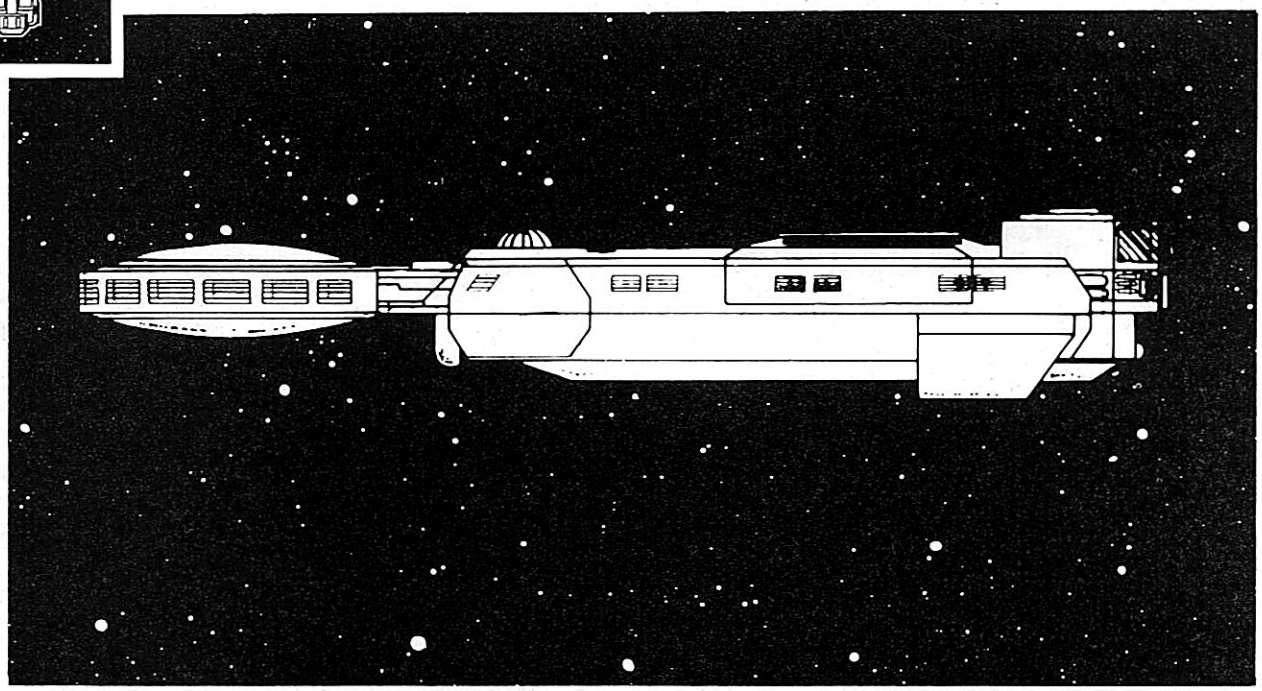
Armament

4 turret hardpoint sockets fitted.

Accommodations

Life Support: Extended (1.68 MW), Gravitic Compensators (6G; 42 MW)
Crew: 15 (2×Maneuver, 2×Electronics, 4×Engineering, 1×Command, 6×Surveyor Specialist)
Crew Accommodations: 1×Small Stateroom (command; 0.0005 MW), 7×Large Stateroom (double-occupancy; 0.001 MW ea.)
Cargo: 388 m³, one large cargo hatch
Small Craft and Launch Facilities: 50-ton modular cutter with internal hangar (1 each Fuel Scoop and Lab modules carried), 3×Air Raft with internal hangars, all four with launch ports
Air Locks: 6

Notes



Fuel purification machinery (3.6 MW), 46.5 hours to refine 5580 m³ (398.6 tons)

Bastien-Class Subsidized Liner

General Data

Displacement: 600 tons
Length: 69 meters
Price: MCr169.55
Configuration: Slab SL
Mass (Loaded/Empty): 4985.02/4154.33
Hull Armor: 10
Volume: 8400 m³
Target Size: S
Tech Level: 12

Engineering Data

Power Plant: 426 MW Fusion Power Plant (47 MW/hit), 1 year duration (0.307 MW excess power)
Jump Performance: 3 (1680 m³ fuel)
G-Rating: 1G (300 MW/G), Contra-Grav lifters (60 MW)
G-Turns: 76 (120.8 using jump fuel), 37.5 m³ of fuel each
Maint: 249

Electronics

Computer: 3×TL-12 Mod St Computer (0.4 MW ea.)
Commo: 30,000km radio (1 hex; 1 MW), 1000 AU maser (∞; 0.6 MW)
Avionics: TL-10+ Avionics
Sensors: Passive EMS fixed array 30,000km (1 hex; 0.03 MW), Active EMS, 3000km (0 hexes; use long range for task difficulty in same hex; 8 MW)
Controls: Flight deck with 4×workstation, plus 4 other workstations

Armament

3 turret hardpoint sockets fitted (Loc: 11; Arcs: All; Loc: 12,13; Arcs: 2,3,4)

Accommodations

Life Support: Extended (1.68 MW), Gravitic Compensators (3G; 42 MW)
Crew: 12 (2×Maneuver, 1×Electronics, 4×Engineering, 1×Maintenance, 2×Stewards [double as Small Craft Pilots], 1×Command, 1×Medical).
Crew Accommodations: 1×Small Stateroom (0.0005 MW ea.), 6×Large Stateroom (double-occupancy; 0.001 MW ea.)
Passenger Accommodations: 21×Small Stateroom (0.0005 MW ea.), 20×Low Berth (0.001 MW ea.)
Cargo: 429.6 m³, one large cargo hatch
Small Craft and Launch Facilities: 10-ton Skiff in Internal Hangar (Minimal), with one launch port
Air Locks: 6

DAMAGE TABLES

19-20		Eng	MD-1H
			Hangar-3H
			All Others-(1h)

Notes

The *Bastien*-class liner is quite similar to the more well-known Stellar class, but keeps its launch in an internal hangar, rather than in an external grapple, and carries a different arrangement of turret hardpoints.

Fuel purification machinery (10.44 MW), 15.62 hours to refine 4530 m³ (323.6 tons)

Broadsword-Class Mercenary Cruiser

General Data

Displacement: 800 tons
Length: 28 meters
Price: MCr315.16
Configuration: Sphere SL
Mass (Loaded/Empty): 6404.67/3636.90
Hull Armor: 28
Volume: 11,200 m³
Target Size: S
Tech Level: 15

Engineering Data

Power Plant: 1050 MW Fusion Power Plant (262.5 MW/hit), 1 year duration (5.206 MW power shortfall)
Jump Performance: 3 (2240 m³ fuel)
G-Rating: 2 (400 MW/G), Contra-Grav lifters (80 MW)
G-Turns: 48 (92.8 using jump fuel), 50 m³ of fuel each
Maint: 177

Electronics

Computer: 3×TL-15 Mod Fb Computers (1.1 MW ea.)
Commo: 300,000km radio (10 hexes; 10 MW), 1000 AU maser (∞; 0.6 MW)
Avionics: TL-10+ Avionics
Sensors: Passive EMS folding array 150,000km (5 hexes; 0.15 MW), Active EMS 300,000km (10 hexes; 15 MW)
ECM/ECCM: 300,000km EMS jammer (10 hexes; 30 MW), EM Masking (11.2 MW)
Controls: Bridge with 15×Workstation, plus 7 other workstations

Armament

Offensive: 8×TL-15 150-Mj Laser Turret (Loc:2-5; Arcs: 1,2,3; Loc: 12-15; Arcs: 2,3,4,5; 4.2 MW ea.; 1 Crew ea.)
Master Fire Directors: 2 TL-15 (6 Diff Mod; No Msl; 10 hexes; 1.56 MW; 1 Crew)

	Short	*Medium*	*Long*	*Extreme*
150-Mj Laser Turret	10:1/10-31	20:1/10-31	40:1/10-31	80:1/10-31

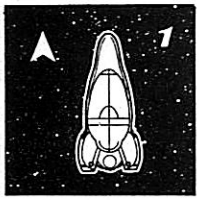
Accommodations

Life Support: Extended (2.24 MW), Gravitic Compensators (6G; 56 MW)
Crew: 72 (7×Engineering, 1×Electronics, 2×Maneuver, 10×Gunnery, 2×Maintenance, 31×Ship's Troops, 6×Small Craft Flight Crew, 10×Command, 2×Steward, 1×Medical).
Crew Accommodations: 26×Small Stateroom (single/double-occupancy; 0.0005 MW ea.), 8×Large Stateroom (quadruple-occupancy; 0.001 MW ea.)
Cargo: 555 m³ (plus 812 m³ for cutter modules), 5 large cargo hatches
Small Craft and Launch Facilities: 2×50-ton modular cutters in docking rings (rings accommodate 50-ton streamlined needle hulls), each with its own launch port (each cutter with one fuel scoop module and one ATV module), 2×ATV (in modules), 1×Air Raft with internal hangar (Minimal) and launch port
Air Locks: 8

Notes

This *Broadsword* variant gives up G-hours and internal comfort for improved jump and maneuver performance, plus an ECM/ECCM suite. Because of its power shortfall, the ship's EMS jammer may only be run at the 180,000 km (6 hexes; 22 MW) power level while at full thrust or while the CG lifters are engaged.

The docking ring housings for the two cutters do not allow maintenance or repair work to be done on them while they are docked. The modules (carried as cargo, 406 m³ each) may not be swapped while the cutters are docked; this must be done outside of the ship.



Fuel purification machinery (9.067 MW), 15.35 hours to refine 4640 m³ (331.4 tons).

Accommodations

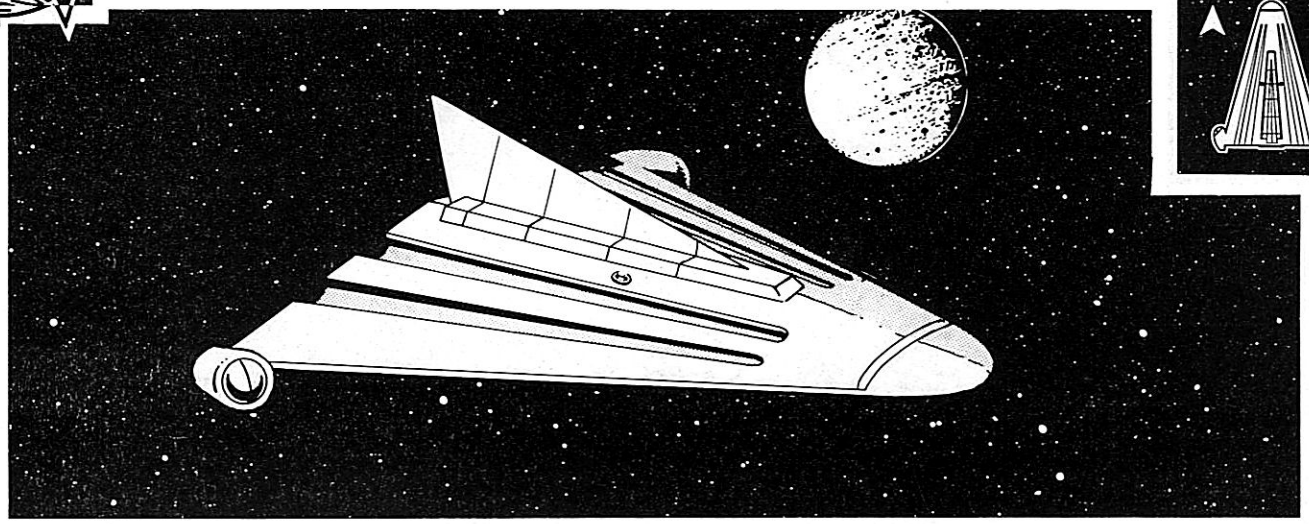
Life Support: Extended (2.66 MW), Gravitic Compensators (6G; 66.5 MW)
Crew: 54: 21×Engineering, 2×Electronics, 2×Maneuvering, 15×Gunnery, 2×Maintenance, 3×Flight Crew, 7×Command, 2×Steward
Crew Accommodations: 8×Small Stateroom (single-occupancy; 0.0005 MW ea.), 23×Small Stateroom (double-occupancy; 0.0005 MW ea.)
Passenger Accommodations: None
Other Facilities: Electronics Shop (0.6 MW), Machine Shop (1 MW)
Cargo: 69.4 m³, plus 30 missiles, one large cargo hatch
Small Craft and Launch Facilities: External Grapple (USL) for 50-ton Cutter
Air Locks: 10

Notes

No fuel purification machinery, 6875 m³ fuel.

Because it is intended to serve as a Fleet unit, the *Chrysanthemum* is dependent on tankers for refueling.

Because the control panels are optimized for smaller ships, some systems on larger ships may require each hit box to record 2 hits (each hit is a slash; two slashes in the form of an "x" fill the box) or the use of additional unused boxes from other lines, such as "other."



When the cutter is detached, "cutter" surface hits are taken against the grapple.

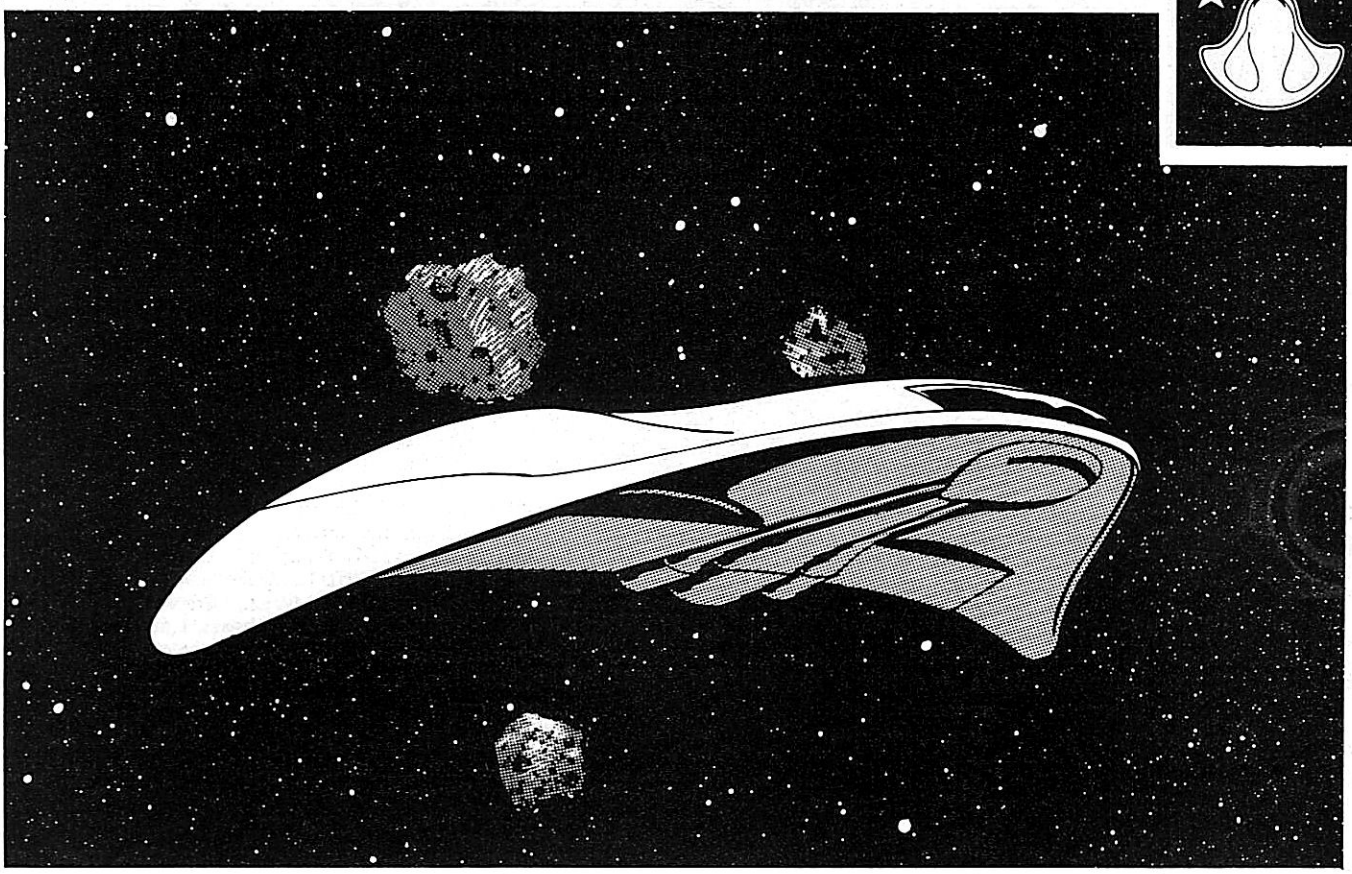
Air Locks: 30

Notes

Fuel purification machinery (100.875 MW), 6 hours to refine 20,175 m³.



Because the control panels are optimized for smaller ships, some systems on larger ships may require each hit box to record 2 hits (each hit is a slash; two slashes in the form of an "x" fill the box) or the use of additional unused boxes from other lines, such as "other."

Zhodani *Ninz*-Class Scout

General Data

Displacement: 100 tons
Length: 35 meters
Price: MCr58.41
Configuration: Wedge AF
Mass (Loaded/Empty): 1100.25/957.05
Hull Armor: 56
Volume: 1400 m³
Target Size: S
Tech Level: 14

Engineering Data

Power Plant: 153 MW Fusion Power Plant (76.5 MW/hit), 1 year duration (1.2645 MW excess power)
Jump Performance: 2 (210 m³ of fuel)
G-Rating: 2 (50 MW/G), Contra-Grav lifters (10 MW)
G-Turns: 56 (89.6 using jump fuel), 6.25 m³ of fuel each
Maint: 31

Electronics

Computer: 3×TL-14 Mod St Computers (0.5 MW ea.)
Commo: 300,000km radio (10 hexes; 10 MW), 1000 AU maser (∞; 0.6 MW)
Avionics: TL-10+ Avionics
Sensors: 150,000km Passive EMS folding array (5 hexes; 0.15 MW), Active EMS 300,000km (10 hexes; 15 MW)
ECM/ECCM: EM Masking (1.4 MW)
Controls: Bridge with 4×Bridge Workstation, plus 1 other workstation

Armament

Offensive: 1×TL-14 150-Mj Laser Turret (Loc: 10; Arcs: 1,2,3; 4.2 MW; 1 Crew)

	Short	*Medium*	*Long*	*Extreme*
TL-14 150-Mj Las Trt	2:1/10-31	4:1/10-31	8:1/10-31	16:1/10-31

Accommodations

Life Support: Extended (0.28 MW), Gravitic Compensators (5G; 7 MW)
Crew: 5: 1×Engineering, 1×Electronics, 2×Maneuvering, 1×Gunnery
Crew Accommodations: 1×Small Stateroom (single-occupancy, 0.0005 MW ea.) 2×Small Stateroom, (double-occupancy, 0.0005 MW ea.)
Passenger Accommodations: 6×Small Stateroom (0.0005 MW ea.)
Cargo: 94.6 m³, one small cargo hatch
Small Craft and Launch Facilities: Air raft in internal bay (Minimal), one launch port
Air Locks: 1

Notes

Fuel scoop and purification machinery (1.4 MW), 12 hours to refine 560 m³. Bridge has one excess workstation, for use by observer or psionic adept.

Reformation Coalition *Aurora*-Class Clipper

General Data

Displacement: 600/1080/2080 tons
Length: 144 meters
Price: MCr749.86
Configuration: Open Frame USL
Mass (Loaded/Empty): 17,404.69/13,311.09
Hull Armor: 20
Volume: 8400/14,000/28,000 m³
Target Size: M (L)
Tech Level: 12

Engineering Data

Power Plant: 2280 MW Fusion Power Plant (50 MW/hit), 1 year duration
Jump Performance: 2 at 2080 tons, 3 at 1560 tons, 4 at 1248 tons (Group III only), 5 at 1040 tons (Group III only) (Fuel used per jump varies with displacement and jump distance, but is always 4368m³ for maximum jump at current displacement.)
G-Rating: 2 at all displacements, limited by hull construction. Divide displacement (in 14 m³ tons) by 2 to get MW needed per G of performance. No contra-grav lifters.
G-Turns: Assuming fuel from fuel skimmer (3500 m³) and 400-ton fuel module (4722 m³), 8222 m3 fuel is available, but fuel use varies with displacement. At 2080 tons, 130 m3 fuel per G-turn. For other configurations, divide MW/G by 8 to get m³ of fuel per G-turn for current displacement.
Maint: 630

Electronics

Computer: 1×TL-12 Mod Fb Computer (0.8 MW), 2×TL-12 Mod St Computer (0.4 MW)
Commo: 300,000km radio (10 hexes; 10 MW), 1000 AU maser (∞; 0.6 MW)
Avionics: TL-10+ Avionics
Sensors: Passive EMS fixed array 120,000km (4 hexes; 0.15 MW), Active EMS 300,000km (10 hexes; 27.5 MW)
ECM/ECCM: EM Masking (8.4 MW)
Controls: Bridge with 18×Bridge Workstation, plus 26 other workstations

Armament

Offensive: 8×TL-12 120-Mj Laser Turret (Loc: 4,5,5—Arcs: 1,2,3,4; Loc: 10—Arcs: All; Loc: 18,19,20,20—Arcs: 2,3,4,5; 3.3 MW ea.; 1 Crew ea.), TL-12 1000-Mj Meson Gun (Loc: Spinal; Arcs: 1; 27.8 MW; 5 Crew)
Master Fire Directors: 3×TL-12 MFD (4 Diff Mods; No Msl, 10 hexes; 2.95 MW ea.; 1 Crew ea.)

	Short	*Medium*	*Long*	*Ext*
120-Mj Laser Turret	4:1/5-27	8:1/5-27	16:1/5-20	32:1/5-10
1000-Mj Meson Gun	5:158	10:75	20:38	40:19

Accommodations

Life Support: Extended (1.68 MW), Gravitic Compensators (3G; 42 MW)
Crew: 85: 26×Engineering, 2×Electronics, 2×Maneuvering, 16×Gunnery, 7×Maintenance, 18×Flight Crew, 11×Command, 2×Steward, 1×Medical
Crew Accommodations: 20×Small Stateroom (double-occupancy; 0.0005 MW ea.). Additional accomodations for crew contained in 100-ton auxiliary quarters module.
Passenger Accommodations: None, but additional quarters modules may be added.
Cargo: 149 m³, plus cargo modules, one small cargo hatch
Small Craft and Launch Facilities: External grapples (USL) for 50-ton Cutter, 30-ton craft, 1×400-ton fuel skimmer, and 4×100-ton, 1×200-ton, and 1×400-ton auxiliary modules.
Air Locks: 6

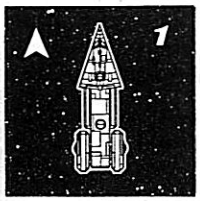
Notes

Clipper carries no fuel of its own. All reaction mass and jump fuel carried in *Manta*-class fueler and fuel modules. Listed price does not include *Manta*, but *Manta*'s loaded mass is included with the clipper's loaded mass, along with loaded mass of one modular cutter and one 30-ton boat (which account for the extra 80 tons of displacement). Price and mass does not include any modules, although clipper is typically fitted at least with one 100-ton auxiliary quarters module and a 400-ton fuel module. The fuel module carries 4722.4 m³ of fuel, plus fuel purification machinery (9.9 MW) sufficient to purify that amount in 17.17 hours.

The Group III clippers are later models with recovered higher technology jump drives.

Fully loaded clipper only has an actual target size of medium (M), but because its laser turrets are all mounted on turret extenders, it is treated as a large (L) target when being scanned by active sensors.

On the damage table, modules A, B, C, and D are 100-ton modules, module E is a 200-ton module, and module F is a 400-ton module, almost always a fuel module.



When clipper is empty, treat as Open Frame for purposes of hit location and fire arcs. When loaded with any modules, use Close Structure. When *Manta* is not docked, treat hits on areas 12, 13, 16, and 17 as a surface hit on its 400-ton grapple, then reroll for interior hit location on 1D10+10.

For hits on fuel module, use 1-18: Fuel, 19-20: Fuel Purification, with FP-13H. Hits on a 100-ton quarters module are treated as SSR hits, there are 43 such rooms. Other locations should be handled abstractly as cargo.

Covenanter-Class Scout Cruiser

General Data

Displacement: 500 tons
Length: 75 meters
Price: MCr241.7
Configuration: Wedge SL
Mass (Loaded/Empty): 5340.61/4405.73
Hull Armor: 30/62
Volume: 7000 m³
Target Size: S
Tech Level: 12/15

Engineering Data

Power Plant: 891 MW Fusion Power Plant (99 MW/hit), 1 year duration, plus 38.4 MW auxiliary fusion plant (38.4 MW/hit), 1 year duration
Jump Performance: 2 (1050 m³ fuel)
G-Rating: 3 (250 MW/G), Contra-Grav lifters (50 MW)
G-Turns: 48 (59.2 allowing fuel for jump 1, 81.6 using all jump fuel), 31.25 m³ of fuel each
Maint: 156

Electronics

Computer: 3×TL-15 Model St (0.55 MW ea.)
Commo: 2×300,000km radio (10 hexes; 10 MW), 2×1000AU maser (∞; 0.6 MW)
Avionics: TL-10+ Avionics
Sensors: Passive EMS folding array 150,000km (5 hexes; 0.15 MW), Active EMS 300,000km (10 hexes; 15 MW), TL-15 Densitometer (0.4 MW), TL-14 Neutrino Sensor (0.01 MW)
ECM/ECCM: EMS jammer (10 hexes; 30 MW), EM Masking package (6.58 MW)
Controls: Bridge with 7×Bridge Workstation, plus 6 other workstations

Armament

Offensive: 3×TL-14 150-Mj Laser Turret (Loc: 2/3; Arcs: 1,2,3; 4.2 MW; 1 Crew; Loc: 16,17; Arcs: All; 4.2 MW ea.; 1 Crew ea..), 1×300-Mj Laser Barbette (Loc: 10; Arcs: 1,2,3; 8.3 MW; 1 Crew), 1×Missile/RCV Barbette (Loc: 11; 5 ready Msls or recce drones; 0.15 MW; 1 Crew)
Master Fire Directors: 1 TL-14 (5 Diff Mod; Non-Msl; 10 hexes; 1.62 MW; 1 Crew)

	Short	*Medium*	*Long*	*Extreme*
150-Mj Laser Turret	2:$^{1}/_{10}$-31	4:$^{1}/_{10}$-31	8:$^{1}/_{10}$-31	16:$^{1}/_{10}$-31
300-Mj Laser Barbette	10:$^{1}/_{14}$-43	20:$^{1}/_{14}$-43	40:$^{1}/_{8}$-26	80:$^{1}/_{4}$-13

Accommodations

Life Support: Extended (1.036 MW), Gravitic Compensators (5G; 32.9 MW)
Crew: 35 (6×Engineering, 1×Electronics, 2×Maneuver, 6×Gunnery, 1×Maint, 3×Small Craft, 3×Command, 1×Medic, 6×Scouts, 6×Troops)
Crew Accommodations: 1×Small Stateroom (0.0005 MW), 17×Large Stateroom (0.001 MW)
Small Craft and Launch Facilities: External grapple for 30-ton small craft, Internal hangars for 2 air rafts, 2 tracked ATVs, 1 launch port each
Additional Fittings: 5×Air Lock, 247.5 m³ cargo with 1 large hatch, 8-ton sick bay (0.8 MW), 2×8-ton lab (0.8 MW ea.), 10-ton machine shop (1 MW), 6-ton electronics shop (0.6 MW)

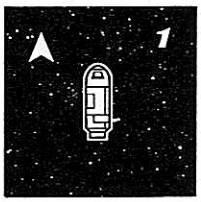
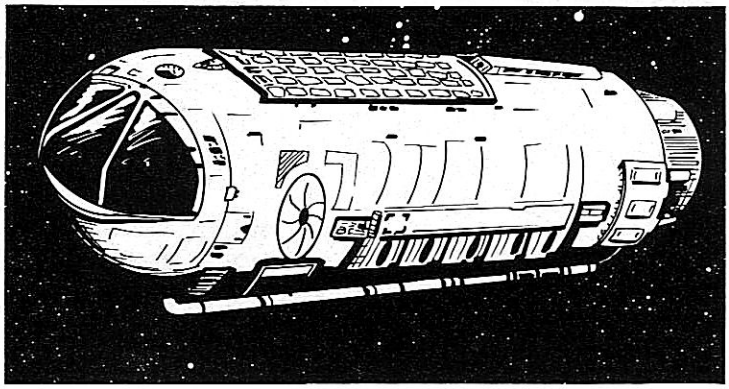
Notes



Built by the Covenant of Sufren from cannibalized TL-14 *Gazelle* and TL-15 Scout hulls, with locally manufactured TL-12 components.

Systems consume 929.4 MW. *Gazelle* drop tanks are now permanently attached.

2550 m³ of fuel (not counting 94.86 m³ reactor fuel), 1050 m³ needed for jump 2, 700 m³ for jump 1. Fuel purification machinery (3.1875 MW) sufficient to purify 637.5 m³ in 6 hours (24 hours for entire load).



Surface hit locations 1-5 have armor 30, all others have 62.

Skiff & Ship's Boat

General Data

Displacement: 10 tons
Length: 14 meters
Price: MCr9.9
Configuration: Cylinder, SL
Mass (Loaded/Empty): 83.99/74.83
Hull Armor: 14
Volume: 140 m³
Target Size: VS
Tech Level: 12

Engineering Data

Power Plant: 14MW Fusion Power Plant (14 MW/hit), 1 year duration (0.255 MW power shortfall)
G-Rating: 1 (5 MW/G), Contra-Grav lifters (1 MW)
G-Turns: 16, 0.625 m³ of fuel each
Maint: 3

Electronics

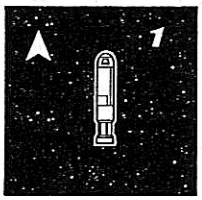
Computer: 2×TL-12 Model St (0.4 MW each)
Commo: 30,000km radio (1 hex; 1 MW), 1000 AU maser (∞; 0.6 MW)
Avionics: TL-10+ Avionics
Sensors: Passive EMS fixed array 30,000 km (1 hex; 0.03 MW), Active EMS 300 km (0 hexes; use extreme range for task difficulty in same hex; 5 MW)
Controls: Flight deck with 2×workstation

Armament

None

Accommodations

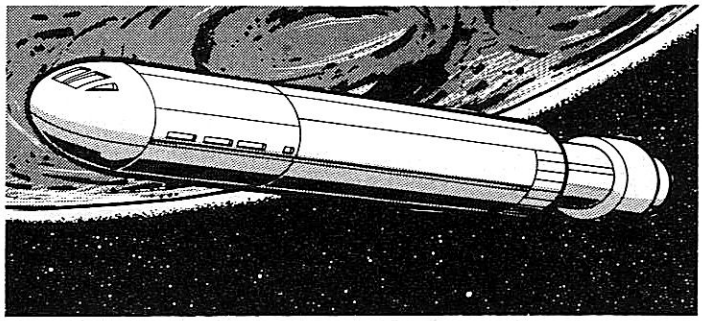
Life Support: Basic (0.014 MW), Gravitic Compensators (3G; 0.7 MW)
Crew: 2 (1×Maneuver, 1×Electronics)
Crew Accommodations: 2×Workstation
Passenger Accommodations: 20×Seat (Adequate)
Cargo: 8.46m³, one small cargo hatch
Small Craft and Launch Facilities: None
Air Locks: 1



Notes

Passenger seats may be removed, each adding 3.5 m³ to the cargo capacity. Must shut down radio or maser when taking off.

No fuel purification machinery, 10 m³ (0.7 tons) of reaction mass is carried.



DAMAGE TABLES

Area (1D20)	*Surface Hits*	*Internal Explosion*	*Systems*
1		Hold	PP-1H

10-17		Hold	
18-19		1-5: Eng, 6-20: Hold	
20		Eng	

General Data

Displacement: 30 tons
Length: 27.6 meters
Price: MCr17.67
Configuration: Needle SL
Mass (Loaded/Empty): 428.08/378.48
Hull Armor: 40
Volume: 420 m³
Target Size: VS
Tech Level: 12

Engineering Data

Power Plant: 90MW Fusion Power Plant (45 MW/hit), 1 year duration (17.297 MW excess power)
G-Rating: 4 (15 MW/G), Contra-Grav lifters (3 MW)
G-Turns: 96, 1.875 m³ of fuel each
Maint: 14

Electronics

Computer: 2×TL-12 Model St (0.4 MW ea.)
Commo: 30,000km radio (1 hex; 1 MW), 1000 AU maser (∞; 0.6 MW)
Avionics: TL-10+ Avionics
Sensors: Passive EMS fixed array 30,000 km (1 hex; 0.03 MW), Active EMS 300 km (0 hexes; use extreme range for task difficulty in same hex; 5 MW)
Controls: Flight deck with 2×workstation, plus 1 other workstation

Armament

None

Accommodations

Life Support: Basic (0.042 MW), Gravitic Compensators (3G; 2.1 MW)
Crew: 3 (1×Engineering, 1×Electronics, 1×Maneuver)
Crew Accommodations: 3×Workstation
Passenger Accommodations: 20×Seat (Adequate)
Cargo: 37 m³, one small cargo hatch
Air Locks: 1

Notes

Passenger seats may be removed, each adding 3.5 m³ to the cargo capacity. No fuel purification machinery, 180m³ (12.86 tons) of reaction mass is carried.

The Ship's Boat design has 17.3 MW of power left over, which allows the mounting of weapons or more powerful sensors at the expense of cargo space.

Modular Cutter & Shuttle

General Data

Displacement: 50 tons **Hull Armor:** 30
Length: 33 meters **Volume:** 700 m³
Price: MCr18.98 (cutter alone) **Target Size:** VS
Configuration: Needle SL **Tech Level:** 12
Mass (Loaded/Empty): 353.82/340.72 cutter alone
727.45/684.96 with fuel module

Air Locks: 1

Engineering Data

Power Plant: 100 MW Fusion Power Plant (50 MW/hit), 1 year duration (10.9196 MW excess power used to power modules)
G-Rating: 3 (25 MW/G), Contra-Grav lifters (5 MW)
G-Turns: 48, 3.125 m³ of fuel each
Maint: 13, +13 for fuel module

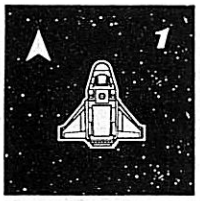
Electronics

Computer: 2×TL-12 Model St (0.4 MW ea.)
Commo: 30,000km radio (1 hex; 1 MW), 1000 AU maser (∞; 0.6 MW)
Avionics: TL-10+ Avionics
Sensors: Passive EMS fixed array 30,000 km (1 hex; 0.03 MW), Active EMS 300 km (0 hexes; use extreme range for task difficulty in same hex; 5 MW)
Controls: Flight deck with 2×workstation, plus 1 other workstation

Accommodations

Life Support: Basic (0.0294 MW), Gravitic Compensators (3G; 1.47 MW)
Crew: 3 (1×Engineering, 1×Electronics, 1×Maneuver)
Crew Accommodations: Flight Deck
Passenger Accommodations: Varies depending upon module fitted.
Cargo: Varies depending upon module fitted (388 m³ in cargo module), 2.6 m³ in cutter

Notes



Modular Cutter may be fitted with a variety of 29-ton (406m³) modules, including lab module (336.3 tonnes loaded/284.4 empty, MCr14.12), passenger/cargo module (311.59 tonnes loaded/133.59 empty, MCr0.4, carries 30 passengers and 178 m³ cargo—passenger seats, 7 m³ each, can be traded for cargo or for smaller seats, but if cargo mass exceeds 284 tonnes, cutter G-rating will drop to 1G), ATV module (211.84 tonnes loaded/161.84 empty, MCr0.16, includes space for a single ATV of up to 50 tonnes).

Data assumes the fitting of a fuel scoop module (373.63 tonnes loaded/344.24 empty, MCr0.17). The module can scoop and carry 277 m³ (19.8 tons) of fuel and has fuel purification machinery sufficient to refine 277 m³ in 6 hours.

Difficulty Modifier

BRILLIANT LANCES™ Player Aids Card

Traveller® Starship Combat

SENSOR AND FIRE TASKS DIFFICULTY MODIFIER FLOWCHARTS

When calculating the Diff Mods below, use the scale provided on the left margin of this card to help in keeping a running total. Hold the card so that your left thumb and forefinger are free to move up and down the scale, "pinching" the current Diff Mod total.

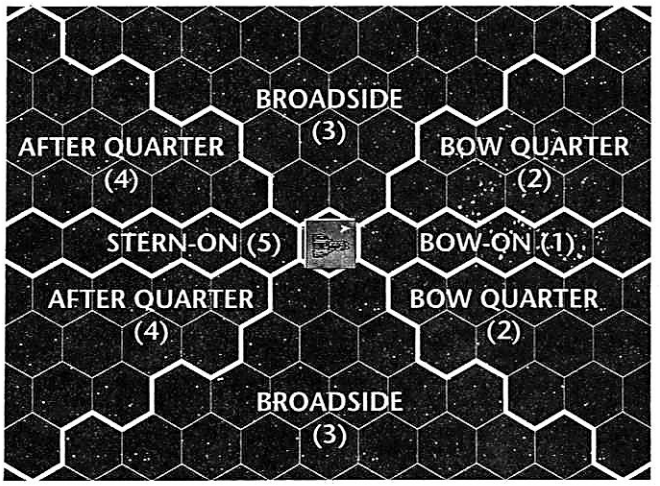
SENSOR TASK DIFFICULTY MODIFIERS: SENSING PLAYER

The player attempting a Sensor Task computes a total Difficulty Modifier based on the following criteria and combines this cumulative Diff Mod with the cumulative Diff Mod reported by the target player. This final combined Diff Mod is applied to the base difficulty level based on the sensor's range performance when rolling the Sensor Task. No difficulty level may be reduced to less than Easy.

1. If task is an attempt to **retain a lock** from a previous turn, **–1 Diff Mod**. (Cannot be combined with 2.)
2. If task is using a **handed-off sensor lock** from another sensor on the same or a different ship, **–1 Diff Mod.** (Cannot be combined with 1.)
3. If sensing ship suffered a **Catastrophic Failure at an Evasion Task** this turn, **+1 Diff Mod**.
4. If sensor line of sight **passes through an Area Jamming** area of effect, **+1 Diff Mod per area**.
5. If a **Planet or Asteroid** counter is in the target's hex, **+1 Diff Mod.**
6. If there are any **White Out** (missile detonation) markers in the target's hex, **+1 Diff Mod per marker.**
7. If target has **gone active** on the current turn (using active sensors or radio) and the sensing vessel is within twice the active sensor's extreme range, and has a direction finder or passive EMS sensor with a tech level equal to or greater than the active sensor, **–1 Diff Mod.**
8. If target is the **source of Area Jamming**, and the sensing vessel is within 80 hexes of the area jammer, and has any form of functioning direction finder or passive EMS, **–2 Diff Mod.**

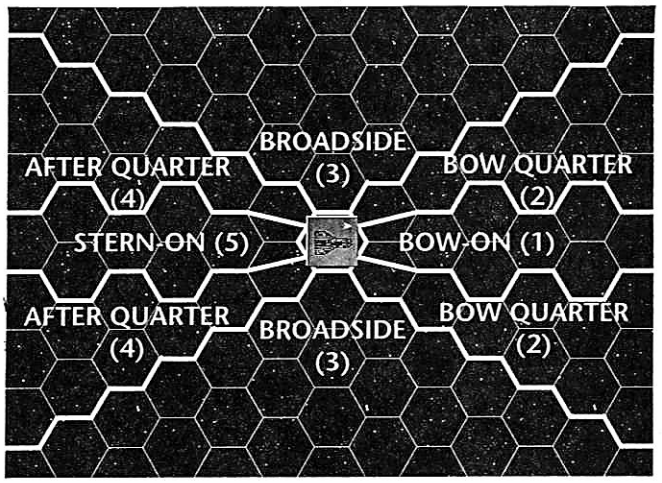
SENSOR TASK DIFFICULTY MODIFIERS: TARGET PLAYER

The player controlling the target of a Sensor Task computes a total difficulty modifier based on the following criteria and reports the total to the sensing player.



1. The **Constant Diff Mods** value which corresponds to the sensor being used by the sensing player, taken from the table on the Control Panel. Diff Mod ranges from **+4 to –5 Diff Mods**. This combined Diff Mod includes:
   A: Difficulty Modifer for target size (+2 to –5 Diff Mods), and
   B: EMM (Electromagnetic Masking) Difficulty Modifier according to type of sensor, +1 or +2 Diff Mods, or +0 if no EMM is fitted.
   If the EMM suite has been damaged so that it no longer functions, the player should remember to line out the EMM line of the Constant Diff Mods table and use only the target size difficulty modifier.
2. If successful **jamming** attempt was made against the sensor, **+1 Diff Mod** (or **+2 if Outstanding Success** was rolled).
3. Diff Mods **versus passive sensors only** (HRT or passive EMS) based on target's **use of power plant** for maneuver or evasion.
   - If target spent **no G-turns** this turn, **+1 Diff Mod**
   - If target spent **one or more G-turns** this turn, **+0 Diff Mod**
   - If target **powered down** in "cold mode," **+2 Diff Mod**
   - If target spent **one or more G-turns and is facing stern-on** (Arc 5) to the sensing vessel, **–3 Diff Mod**
4. If the target has a **Passive EMS Array Extended, –1 Diff Mod versus Active sensors only.**
5. If target made a successful **evasion** attempt, **+1 Diff Mod** (on **Outstanding Success, +1 Diff Mod per G-turns spent on evasion ÷2, drop fractions**).
6. If sensor is **ladar** and target has sandcaster and elects to expend a cannister, or already has sand up, **+1 Diff Mod.**
7. If target has a **black globe**, use the following difficulty modifiers:
   - If black globe is **full up**, use **+5 DIff Mod vs. Active Sensors**, and **+3 Diff Mod vs. Passive Sensors.**
   - If black globe is **flickering**, use **+1 Diff Mod per flicker rate ÷30** (round to nearest whole number for both active and passive sensors).

FIRING TASK DIFFICULTY MODIFIERS



The player attempting a Fire Task computes a total cumulative Difficulty Modifier based on the following criteria. This total combined Diff Mod is applied to the base difficulty level based on the weapon's range performance when rolling the Fire Task. No difficulty level may be reduced to less than Easy.

1. Diff Mod based on **target size, +1 to –5,** take from Constant Diff Mods table on Control Panel.
2. If target made a successful **evasion** attempt, **+1 Diff Mod** (on **Outstanding Success, +1 Diff Mod per G-turns spent on evasion ÷2, drop fractions**).
3. **Absolute range** to the target in hexes, **divided by 3 (drop fractions) = + Diff Mods**, or see table above right.
   A: For controlled missiles, use range from controlling ship to target
   B: For semi-independent or fully independent missiles (with their own sensor locks), use range from missile to target.
4. If firing ship rolled **Catastrophic Failure on its own Evasion Task** for the current turn, **+1 Diff Mod.**
5. For **overpowered weapons, disregard 1 or 2 + Diff Mods,** based on additional power supplied, as indicated on control panel.
6. Weapons that are being fired with **MFDs** may **disregard 1 to 6 + Diff Mods,** based on TL, as indicated on control panel.

DAMAGE

Arcs of Fire and Hit Locations by Hull Form

Configuration	*(1) Bow On*	*(2) Bow Quarter*	*(3) Broadside*	*(4) After Quarter*	*(5) Stern On*
Open Frame	1-20	1-20	1-20	1-20	1-20
Needle	1-15	1-19	1-20	2-20	6-20
Wedge	1-19	1-19	2-19	16-20	16-20
Cylinder	1-5	1-15	2-19	6-20	16-20
Box	1-5	1-15	2-19	6-20	16-20
Sphere	1-11	1-15	2-19	6-20	10-20
Dome/Disc	1-11	1-15	2-19	6-20	10-20
Close Structure	1-9	1-15	2-19	6-20	12-20
Slab	1-5, 10-11	1-15	2-19	6-20	10-11, 16-20

Table shows the weapon locations that can fire into the listed arcs (e.g., a laser in location 10 on a sphere hull form could fire into arcs 1, 2, 3, 4, and 5, but on a cylinder hull form could only fire into arcs 2, 3, and 4), as well as the hit locations which can be hit from those listed arcs. When rolling for hits from a particular arc, re-roll all hit locations which are not listed in the appropriate column.

Note: Firing meson guns are subject to arc of fire limitations, but always roll 1D20 for hit location, regardless of the facing of the target. Missiles that denonate and fire in the same hex as their targets also roll 1D20 for hit location, rather than worrying about the target's facing.

Damage Type Chart

Spacecraft Damage

Damage Points	*Result*
0 or less	No effect
1 to 10	1 minor
11 to 20	2 minor
21 to 40	1 major
41 to 60	2 major
61 to 80	3 major
81 to 100	4 major
101 to 120	5 major

No more than 5 major damage hits can be done in a single location. Remaining damage points beyond 120 are rolled as excess damage in another location.

Excess Damage Location

1D6	*Area*
1	-1 internal area
2-3	same internal area
4	+1 internal area
5	-1 surface area
6	+1 surface area

Minor and Non-Destroying Damage Table

1D6	*Damage*
1-3	System reset, operation interrupted for 1 turn
4-6	Performance degraded: All tasks using system at +1 Diff Mod.

Note: If damage is against the crew, a minor damage is 1 crew casualty. If damage is against fuel, ship loses 1D6 tons of fuel before the tanks re-seal. If damage is against sensors, all locks are lost and must be re-rolled when operations resume.

Major Damage

Major damage to a crew section causes 1D6 casualties. If damage is against fuel, ship loses 1D20 tons of fuel before the tanks re-seal.

Penetration Rating Conversions

Damage Value÷Penetration Rating=Penetration Value
Penetration Value×Penetration Rating=Damage Value

(The number is number of Critical Hits applied to the target.)

Proportional Movement Guide

Velocity	*Step 1*	*2*	*3*	*4*	*5*	*6*	*7*	*8*	*9*	*10*
1	—	—	—	—	M	—	—	—	—	—
2	—	—	M	—	—	—	—	M	—	—
3	—	—	M	—	—	M	—	—	M	—
4	—	M	—	—	M	—	M	—	—	M
5	—	M	—	M	—	M	—	M	—	M
6	M	—	M	—	M	M	—	M	—	M
7	M	—	M	M	—	M	M	—	M	M
8	M	—	M	M	M	M	—	M	M	M
9	M	M	M	M	—	M	M	M	M	M
10	M	M	M	M	M	M	M	M	M	M

For craft with a velocity greater than 10, use the line for 10 plus the line for velocity in excess of 10. For example, a vessel with velocity 15 uses the 5 and 10 line. In step 1 it moves one hex, step 2 moves two hexes, and so on. Missiles always detonate at closest approach, so that even if one of the vessels moves two hexes in a step, the missile may detonate before the second hex is moved.

Difficulty Modifier

BRILLIANT LANCES™

Traveller® Starship Combat

Player Aids Card

SENSOR AND FIRE TASKS DIFFICULTY MODIFIER FLOWCHARTS

When calculating the Diff Mods below, use the scale provided on the left margin of this card to help in keeping a running total. Hold the card so that your left thumb and forefinger are free to move up and down the scale, "pinching" the current Diff Mod total.

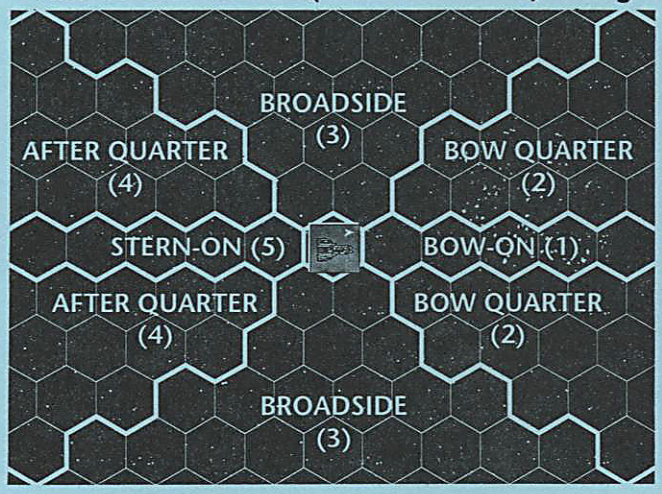
SENSOR TASK DIFFICULTY MODIFIERS: SENSING PLAYER

The player attempting a Sensor Task computes a total Difficulty Modifier based on the following criteria and combines this cumulative Diff Mod with the cumulative Diff Mod reported by the target player. This final combined Diff Mod is applied to the base difficulty level based on the sensor's range performance when rolling the Sensor Task. No difficulty level may be reduced to less than Easy.

1. If task is an attempt to **retain a lock** from a previous turn, **–1 Diff Mod**. (Cannot be combined with 2.)
2. If task is using a **handed-off sensor lock** from another sensor on the same or a different ship, **–1 Diff Mod.** (Cannot be combined with 1.)
3. If sensing ship suffered a **Catastrophic Failure at an Evasion Task** this turn, **+1 Diff Mod**.
4. If sensor line of sight **passes through an Area Jamming** area of effect, **+1 Diff Mod per area**.
5. If a **Planet or Asteroid** counter is in the target's hex, **+1 Diff Mod.**
6. If there are any **White Out** (missile detonation) markers in the target's hex, **+1 Diff Mod per marker.**
7. If target has **gone active** on the current turn (using active sensors or radio) and the sensing vessel is within twice the active sensor's extreme range, and has a direction finder or passive EMS sensor with a tech level equal to or greater than the active sensor, **–1 Diff Mod.**
8. If target is the **source of Area Jamming,** and the sensing vessel is within 80 hexes of the area jammer, and has any form of functioning direction finder or passive EMS, **–2 Diff Mod.**

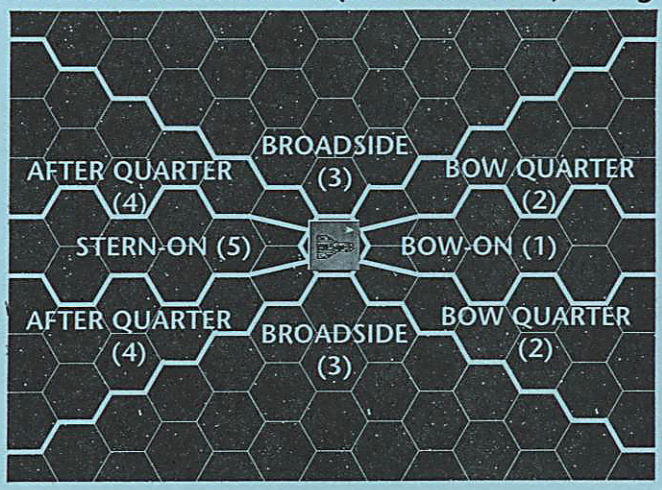
SENSOR TASK DIFFICULTY MODIFIERS: TARGET PLAYER

The player controlling the target of a Sensor Task computes a total difficulty modifier based on the following criteria and reports the total to the sensing player.



1. The **Constant Diff Mods** value which corresponds to the sensor being used by the sensing player, taken from the table on the Control Panel. Diff Mod ranges from **+4 to –5 Diff Mods**. This combined Diff Mod includes:
   A: Difficulty Modifer for target size (+2 to –5 Diff Mods), and
   B: EMM (Electromagnetic Masking) Difficulty Modifier according to type of sensor, +1 or +2 Diff Mods, or +0 if no EMM is fitted.
   If the EMM suite has been damaged so that it no longer functions, the player should remember to line out the EMM line of the Constant Diff Mods table and use only the target size difficulty modifier.
2. If successful **jamming** attempt was made against the sensor, **+1 Diff Mod** (or **+2 if Outstanding Success** was rolled).
3. Diff Mods **versus passive sensors only** (HRT or passive EMS) based on target's **use of power plant** for maneuver or evasion.
   - If target spent **no G-turns** this turn, **+1 Diff Mod**
   - If target spent **one or more G-turns** this turn, **+0 Diff Mod**
   - If target **powered down** in "cold mode," **+2 Diff Mod**
   - If target spent **one or more G-turns and is facing stern-on** (Arc 5) to the sensing vessel, **–3 Diff Mod**
4. If the target has a **Passive EMS Array Extended, –1 Diff Mod versus Active sensors only.**
5. If target made a successful **evasion** attempt, **+1 Diff Mod** (on **Outstanding Success, +1 Diff Mod per G-turns spent on evasion ÷2, drop fractions**).
6. If sensor is **ladar** and target has sandcaster and elects to expend a cannister, or already has sand up, **+1 Diff Mod.**
7. If target has a **black globe**, use the following difficulty modifiers:
   - If black globe is **full up**, use **+5 DIff Mod vs. Active Sensors**, and **+3 Diff Mod vs. Passive Sensors.**
   - If black globe is **flickering**, use **+1 Diff Mod per flicker rate ÷30** (round to nearest whole number for both active and passive sensors).

FIRING TASK DIFFICULTY MODIFIERS



The player attempting a Fire Task computes a total cumulative Difficulty Modifier based on the following criteria. This total combined Diff Mod is applied to the base difficulty level based on the weapon's range performance when rolling the Fire Task. No difficulty level may be reduced to less than Easy.

1. Diff Mod based on **target size, +1 to –5,** take from Constant Diff Mods table on Control Panel.
2. If target made a successful **evasion** attempt, **+1 Diff Mod** (on **Outstanding Success, +1 Diff Mod per G-turns spent on evasion ÷2, drop fractions**).
3. **Absolute range** to the target in hexes, **divided by 3 (drop fractions) = + Diff Mods**, or see table above right.
   A: For controlled missiles, use range from controlling ship to target
   B: For semi-independent or fully independent missiles (with their own sensor locks), use range from missile to target.
4. If firing ship rolled **Catastrophic Failure on its own Evasion Task** for the current turn, **+1 Diff Mod.**
5. For **overpowered weapons, disregard 1 or 2 + Diff Mods,** based on additional power supplied, as indicated on control panel.
6. Weapons that are being fired with **MFDs** may **disregard 1 to 6 + Diff Mods,** based on TL, as indicated on control panel.

Sphere	1-11	1-15	2-19	6-20	10-20
Dome/Disc	1-11	1-15	2-19	6-20	10-20
Close Structure	1-9	1-15	2-19	6-20	12-20
Slab	1-5, 10-11	1-15	2-19	6-20	10-11, 16-20

Table shows the weapon locations that can fire into the listed arcs (e.g., a laser in location 10 on a sphere hull form could fire into arcs 1, 2, 3, 4, and 5, but on a cylinder hull form could only fire into arcs 2, 3, and 4), as well as the hit locations which can be hit from those listed arcs. When rolling for hits from a particular arc, re-roll all hit locations which are not listed in the appropriate column.

Note: Firing meson guns are subject to arc of fire limitations, but always roll 1D20 for hit location, regardless of the facing of the target. Missiles that denonate and fire in the same hex as their targets also roll 1D20 for hit location, rather than worrying about the target's facing.

Damage Type Chart

D10	*Engineering*	*Electronics*	*Quarters*	*Hold*	*Weaponry*	*Antenna*	*Drones*

Abbreviations: **DCP:** Damage Control Personnel; **Def Scrn:** Defensive Screen; **ECM:** ECM and ECCM; **ELS:** Emergency Life Support; **FPP:** Fuel Processing Plant; **Grav Comp:** Gravitic Compensators; **Hngr:** Hangar; **LB:** Low Berths; **Man Drive:** Maneuver Drive (heat exchanger/ignition chamber); **MES:** Machine or Electonics Shops; **MFD:** Master Fire Director (roll on Weaponry column for Mount or Crew)

DMs: **Engineering:** If no jump drive, +2; **Electronics:** If no Defensive Screens, +1, If no Def Screens or ECM, +2; **Quarters:** If no Ship's Troops, +2; if no Ship's Troops or Sick Bay, +3; **Hold:** If no Labs or Hangar, +2; if no Labs, Hangars, or Shops, +3; **Antenna:** If no Defensive Screens, +1, If no Defensive Screens or ECM, +2, If no Defensive Screens, ECM, or MFD, +4; **Drones:** If unarmed, +2

Spacecraft Damage

Damage Points	*Result*
0 or less	No effect
1 to 10	1 minor
11 to 20	2 minor
21 to 40	1 major
41 to 60	2 major
61 to 80	3 major
81 to 100	4 major
101 to 120	5 major

No more than 5 major damage hits can be done in a single location. Remaining damage points beyond 120 are rolled as excess damage in another location.

Excess Damage Location

1D6	*Area*
1	-1 internal area
2-3	same internal area
4	+1 internal area
5	-1 surface area
6	+1 surface area

Minor and Non-Destroying Damage Table

1D6	*Damage*
1-3	System reset, operation interrupted for 1 turn
4-6	Performance degraded: All tasks using system at +1 Diff Mod.

Note: If damage is against the crew, a minor damage is 1 crew casualty. If damage is against fuel, ship loses 1D6 tons of fuel before the tanks re-seal. If damage is against sensors, all locks are lost and must be re-rolled when operations resume.

Major Damage

Major damage to a crew section causes 1D6 casualties. If damage is against fuel, ship loses 1D20 tons of fuel before the tanks re-seal.

Penetration Rating Conversions

Damage Value÷Penetration Rating=Penetration Value

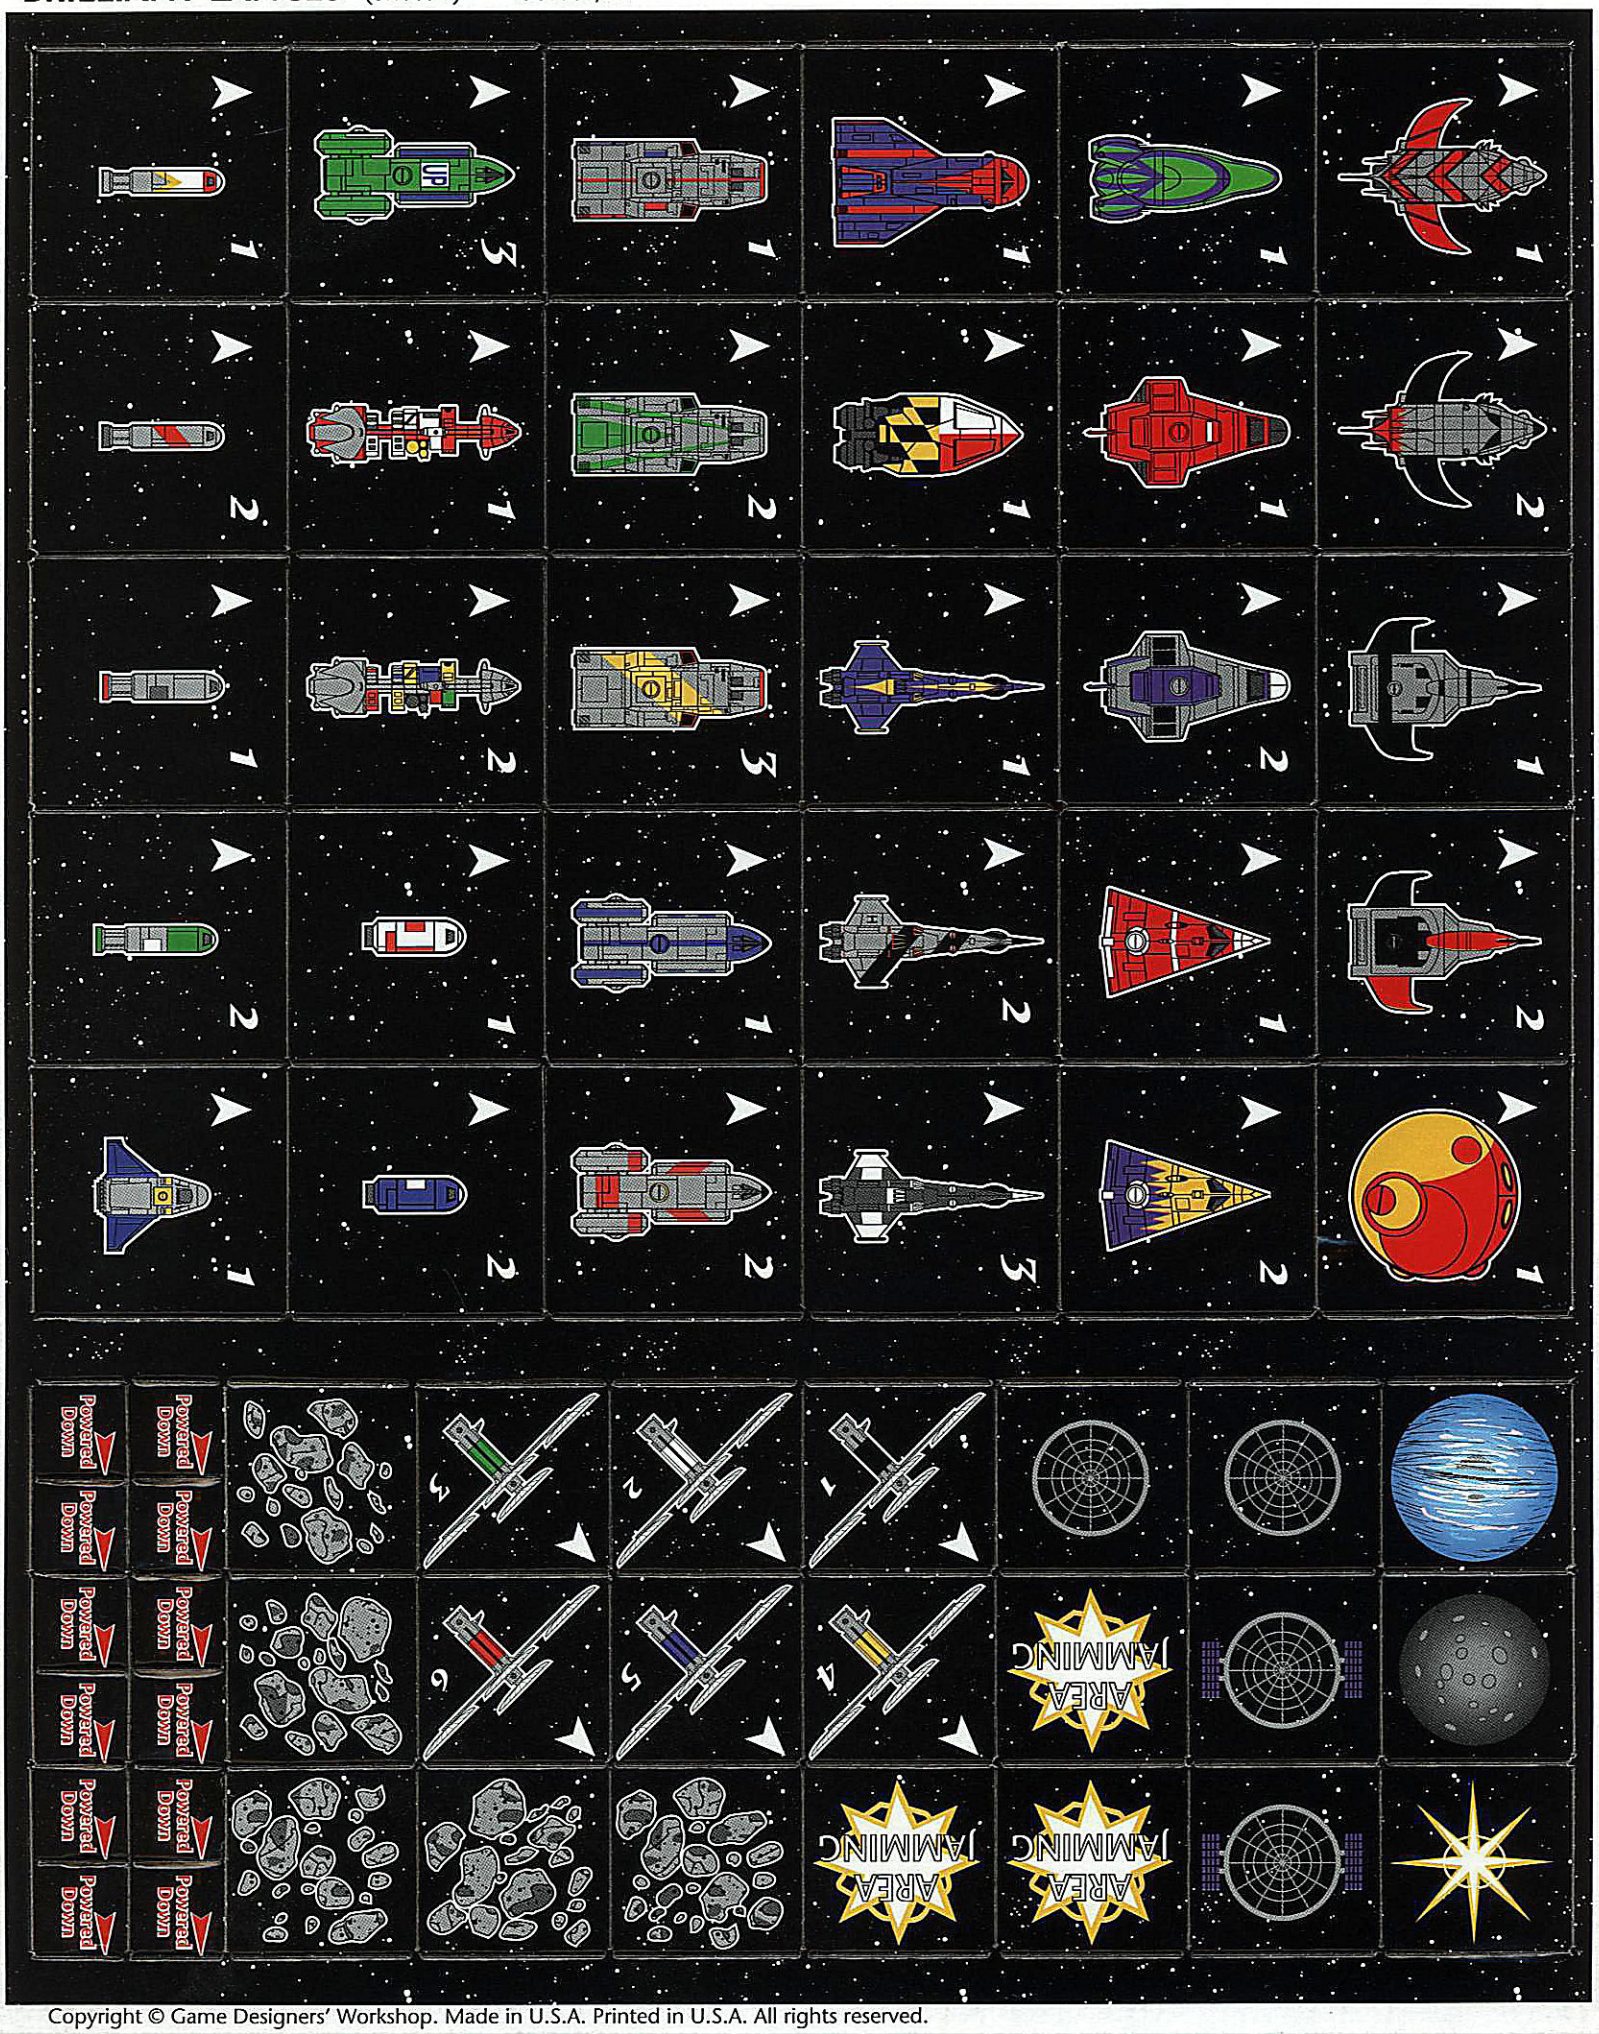
Proportional Movement Guide

Velocity	*Step 1*	*2*	*3*	*4*	*5*	*6*	*7*	*8*	*9*	*10*
1	—	—	—	—	M	—	—	—	—	—
2	—	—	M	—	—	—	—	M	—	—
3	—	—	M	—	—	M	—	—	M	—
4	—	M	—	—	M	—	M	—	—	M
5	—	M	—	M	—	M	—	M	—	M
6	M	—	M	—	M	M	—	M	—	M
7	M	—	M	M	—	M	M	—	M	M
8	M	—	M	M	M	M	—	M	M	M
9	M	M	M	M	—	M	M	M	M	M
10	M	M	M	M	M	M	M	M	M	M

For craft with a velocity greater than 10, use the line for 10 plus the line for velocity in excess of 10. For example, a vessel with velocity 15 uses the 5 and 10 line. In step 1 it moves one hex, step 2 moves two hexes, and so on. Missiles always detonate at closest approach, so that even if one of the vessels moves two hexes in a step, the missile may detonate before the second hex is moved.



Damage Control

BRILLIANT LANCES™

Deadly beams of pure energy

In space combat, you never see your opponent until it's all over, if even then. With acquisition and tracking ranges measured in tens of thousands of kilometers, to human eyes the people that are trying to kill you are not even a speck. But they can hurt you, even though you can't see them. Precise laser arrays and big particle accelerators, honed by centuries of engineering, can reach out without warning to slit your hull like the belly of a fish, spilling life—oxygen, heat, and fuel—into the hard vacuum.

That's why space combat is a game of cat-and-mouse. Keep yourself wrapped in the mantle of space—cold, dark, silent. Keep your thrust burns to a minimum—they blaze like miniature suns for all to detect. Rig your passive sensors to greedily absorb data, but remain quiet yourself—give nothing away. Keep your weapons ready, in case…There! A faint trace of mid-wavelength infrared betrays a maneuver drive. Bring up the ladar dishes while the big passive array builds up a targeting solution. The moments seem endless while every crewmember shares the same thought: "Have they seen us?" Is the unseen enemy at this moment doing the same thing you are?

You might never know the answer. If you beat him, maybe you'll find out. But what if you hadn't seen him first? Some questions must remain unanswered when death, unbidden, comes scorching toward you as silent, brilliant lances.

Brilliant Lances includes:

- Vector-based movement
- Detailed hit location and damage resolution
- Lasers, particle accelerators, meson guns, detonation laser missiles, and the systems that defend against them
- Extensive ship ratings, including New Era and pre-Collapse warships, from the swift Rampart fighter up to large naval and merchant vessels
- Complete starship design rules, usable both with this game and with the **Traveller: The New Era** roleplaying game

INTRODUCTION

In the 57th century, travel between the stars has long been an accepted fact of life. Starships with powerful jump drives form the basis of interstellar commerce, and the warships that protect that commerce.

But jump drives are bulky and take up volume that could be filled with defensive systems or offensive weaponry. A specialized vessel, optimized for large fleet actions, gained popularity during the Second Imperium and came to completely dominate the fleets of the Third Imperium. These vessels had no jump drives, had nothing in fact not directly related to producing the most effective line-of-battle combatant possible.

They were carried from star to star by huge jump tenders, vessels with little or no combat ability of their own which would release their deadly cargo before the battle started and withdraw to a safe distance. These warships became the very symbol of large fleet actions. Because the warships were carried from star to star, they were called battle riders.

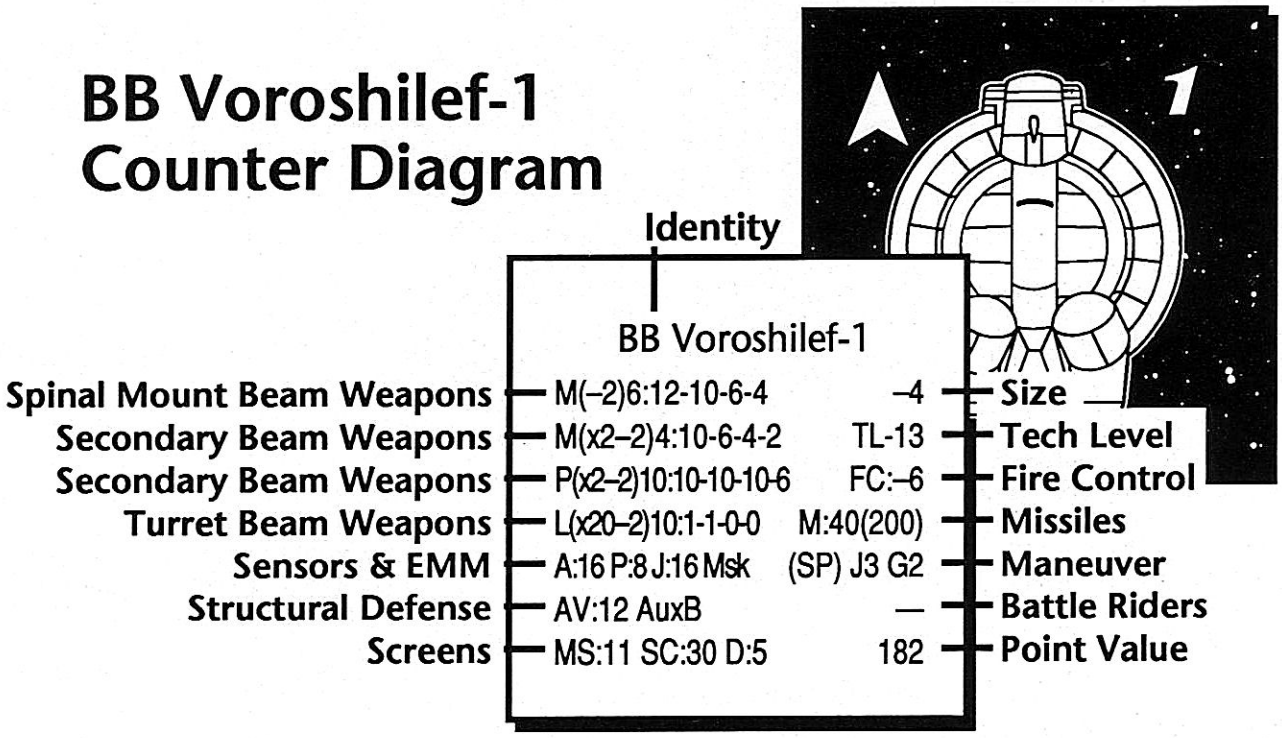
Battle Rider™ is the game of squadron and fleet combat in GDW's **Traveller®** universe. GDW's other space combat boardgame, **Brilliant Lances**, is a detailed and faithful reproduction of individual starship combat, and is very useful for resolving actions between smaller vessels. Because of its level of detail, however, it is unsuited to actions between large groups of vessels. **Battle Rider** undertakes that mission.

COMPONENTS

Battle Rider contains this rules booklet, three 22"x31" maps, three sheets of die-cut cardboard game counters and markers, two reference charts, and several sheets of die-cut game cards. Not included in **Battle Rider**, but necessary for play, are pencils and paper (one each per player).

Battle Rider is one of many games and supplementary products intended for use with the **Traveller: The New Era** science-fiction roleplaying game. However, it is also intended as a stand-alone space combat game, and can be played and enjoyed on its own by players who never intend to play any other **Traveller** products. At many points in the rules below, references are made to concepts detailed elsewhere in the **Traveller** line of materials. While familiarity with these other products may enhance the players' enjoyment of **Battle Rider**, none of these are necessary to understand or play this game. When referring to the **Traveller: The New Era** roleplaying game rulebook, the rules below will sometimes use the abbreviation "TNE."

Rules Booklet: This booklet presents the rules necessary to play **Battle Rider**, as well as the scenarios with which the game is played.



Maps: The three maps are all identical, and portray the vastness of open space within a hexagonal grid which is used to measure distance. Each hexagon measures 30,000 kilometers, or 1/10 of a light-second (the distance that light travels in 1/10 of a second). Note the way that the hexagonal pattern runs off of the map edges.

Unfold the maps and back-fold them against the creases so that they will lie flat. Place the three maps on a table butted up to each other along their short or long edges to form a continuous hexagonal grid.

These maps are duplicates of the maps in the GDW game **Brilliant Lances** and are interchangeable with them. Players who already own **Brilliant Lances** now have a total of six maps to use with either game. Players may also order additional maps from GDW to create as large a playing area as desired.

Counters: The three die-cut counter sheets provide a total of 366 cardboard pieces. Sixty of these are large, measuring 1 1/3 inches square; 42 measure 1 inch square; and the remaining 264 pieces measure 1/2 inch square. These pieces are used in two ways, as "counters" and "markers." A piece which represents a spacecraft, task force, sensor drone, missile, planet, or other object in the game is called a "counter." A marker is a piece which is used to represent the status of certain systems (such as damage or evasion) or conditions on the map (such as Area Jamming and White Out markers).

The ship counters are back-printed with the performance characteristics of the ship. These characteristics are read according to the following diagram:

Identity: Type, class, number.

Beam Weapons: Type (number and/or Diff Mod), close range: damage. Types are lasers (L), particle accelerators (P), and meson guns (M). Numbers of weapons are preceded by an "x" while Diff Mods ignored are preceded by a "–."

Spinal mount beam weapons are long meson guns and particle accelerators mounted along the centerline, or spine, of the ship. If a vessel has two different parallel spinal mount weapons, they are listed in the spinal mount and top secondary beam weapon fields and enclosed in a box. (The *Admiral*-class battle riders, which have both a meson gun and a particle accelerator in the spinal mount position, are examples of this.)

Secondary beam weapons include bay weapons, barbette weapons, and occasionally smaller accelerators mounted radially in a spherical hull ship. (The *Voroshilef*-class battleship is an example of this.)

Turret-mounted beam weapons are lasers usually used as anti-missile weapons.

Sensors: These are listed in the order active sensor (A) and short range, passive sensor (P) and short range, jammer (J) and short range, and electromagnetic masking (Msk). If the passive sensor value is in brackets, the passive sensor array is extendable and retractable.

Structure: The main entry here is the ship's armor value (AV). If the ship has an auxiliary bridge, that is noted here as well.

Screens: These are active defensive systems and are listed in the order meson screen (MS) and value, sandcasters (SC) and number mounted, and nuclear dampers (D) and number mounted.

Size: The number is the size modifier of the vessel. The notation "E" appears on some vessels, but this is used only in the advanced game. (See the Socket Extenders rule, page 19).

Tech Level: The tech level of manufacture.

Fire Control: The number of Diff Mods ignored when firing at a target.

Missiles: If the ship has missiles, the notation "Msl:" will appear here, followed first by the number of missile directors on the ship and then (in parentheses) by the number of ready missiles carried.

Maneuver: This data field covers both interplanetary and interstellar travel capabilities. The first entry (in parentheses) indicates whether the ship can skim (S) and/or process (P) fuel from a gas giant. Next comes the interstellar jump drive (J) capability, if any, and finally the maneuver drive ratings in Gs of acceleration per turn (G). If the G-rating is followed by an asterisk, the vessel has limited maneuver fuel. This has no effect on the basic game, but see the Limited Fuel advanced rule (page 19). The *Gazelle*-class close escort has two jump values separated by a slash, but this has no effect on play of the game.

Battle Riders: This lists the number of battle riders (BR) or light battle riders (BRL) carried by the ship.

Point Value: This is the point value of the ship used for victory determination and and scenario generation. Ships without jump drives have two values separated by a slash. These values differ based on the conditions under which the ship is purchased. See the advanced scenario generation rule (page 19) for a discussion.

Ship Types

BB	Battleship	DD	Destroyer

CVM	Corvette, Missile	SM	Sloop, Multimission

Charts: Two identical cardstock charts are included. These are player aids cards printed with frequently used charts for quick reference. Some of these charts appear in the rules booklet, but keep these charts handy as you read the rules.

Cards: The cards included in the game are used to resolve the success of various sensor and combat tasks in the game. Punch out the cards, shuffle them thoroughly, and place the deck face-down by the map.

There are a total of 96 cards in the game. Ninety-five of these have values printed on them and are uniquely numbered from 1 through 95. The remaining card is blank and may be used to create a replacement for a card lost or damaged. A summary of the values printed on all 95 cards is included on page 29 of this book.

BASIC RULES

GENERAL COURSE OF PLAY

Battle Rider is played in scenarios, each of which represents a hostile encounter between two or more spacecraft. A hostile encounter involves detecting the hostile vessel and maneuvering to intercept or avoid it. Combat involves pinpointing targets with fire control sensors, and performing successive attacks (such as missile fire, laser shots, or spinal meson fire) on the located targets.

Task attempts are made at each point in order to obtain sensor locks and hits; the likelihood of success is established and modified by such considerations as range between the attacker and the target, the type of weapon used, the defensive abilities of the target spacecraft, and other factors. If a hit is obtained, the weapon must penetrate the target's screens and active defenses (such as laser fire destroying incoming missiles). Actual success is determined by turning a card and reading its results. The damage inflicted depends on the type of weapon.

The game continues until one side is vanquished, flees, surrenders, or is destroyed.

Definitions

The following terms are used repeatedly in the rules:

Game Turn: The game is played in turns. Each turn represents 30 minutes of elapsed time. Thus, two game turns equal one hour.

Within a single turn, each individual spacecraft is allowed opportunities to maneuver, detect, and attack. Each spacecraft may likewise be detected and attacked by one or more enemy spacecraft as they conduct their turns.

Hex: A hexagonal grid is superimposed over the map to regularize movement and placement of spacecraft. Distance between vessels (used to calculate sensor and weapon range) is measured in hexes, each of which represents an area of space 30,000 kilometers (1/10 of a light-second) from hexside to hexside.

Velocity: The speed of a vessel or missile expressed in hexes per game turn. For reference purposes, a velocity of 1 hex per turn is equal to a speed of 60,000 kilometers per hour.

G: An acceleration of 1G for one game turn (30 minutes). Gs are cumulative; for example, 6 Gs of thrust yields the same final velocity regardless of whether it was generated by accelerating at 1G for six turns, or 6Gs for one turn.

Tasks: All combat activities are resolved as tasks. Each task involves turning a card and comparing the result to a target number. If the card value is equal to or greater than the target number, the task succeeds; if it is less than the target number, the task fails. See the Task Resolution section (page 4) for more details.

Task Force: A group of spacecraft operating together.

Spacecraft: Spacecraft refers to all of the various vehicles that move and fight in **Battle Rider**, and includes starships, small craft, missiles, and sensor drones.

Starships: Starships are the most commonly used type of spacecraft. These are space vessels with interstellar jump drives that allow

them to travel from star system to star system, much faster than light can travel the same distance.

Battle Riders: Large, heavily armed and protected fleet combatants which do not have jump drives fitted.

Manned Craft: This term means a spacecraft that has a living crew (as opposed to missiles and unmanned drones) and refers to both starships and small craft.

Missiles: These are weapons fired from spacecraft that maneuver on the map like other spacecraft, but destroy themselves when attacking their targets.

Drones: These are vehicles that are controlled by an operator from another point, usually a starship. Unlike missiles, drones are not built to be used up with each mission, but are intended to be reused. However, since they have no crew, they can be abandoned or placed at great risk if necessary.

TASK FORCES AND FLEET TACTICS

Combat ships in the game are combined into task forces, and all of the ships in a task force maneuver, evade, and attack together. They are represented on the map by a single Task Force counter until detected. Players may change the composition of task forces during play by detaching or adding ships.

In each scenario, both players will have a specified Fleet Tactics skill level. This skill level is the maximum number of craft which may be placed together in a task force. Players may have fewer craft than this in a task force, but may never have more. There is no limit on the number of task forces in play by either player, except as imposed by the number of ships in play and the level of Fleet Tactics skill.

Dummy Task Forces: Not all task forces need contain ships or sensor drones. Task forces without ships or sensor drones are called "dummy" task forces, and are used to confuse the opposing player. Each side may have dummy task forces in play equal to the Fleet Tactics level of its commander. Note that dummy task forces, once detected and removed from play, can be recreated by splitting them off from another undetected task force. If all task forces are detected, detected dummy task forces cannot be recreated.

TASK RESOLUTION

Every action attempted in **Battle Rider**, whether an evasive maneuver, attempting a sensor lock, or firing a weapon, is a *task*. A task is an attempt by the crewmember operating a particular piece of equipment (maneuver controls, sensors, weapons, etc.) to use his or her skills and training to successfully accomplish the action. The success of these tasks is based upon the difficulty of the task being attempted and the random turn of a card. Success and failure of the task is determined by turning a card and reading the result.

Types of Tasks: Tasks include attempts to detect enemy vessels, obtain sensor locks, jam enemy sensors, fire beam weapons, and defend against enemy fire with defensive screens. Detection, sensor locks, jamming, and fire are range-based tasks, while other tasks are absolute difficulty tasks.

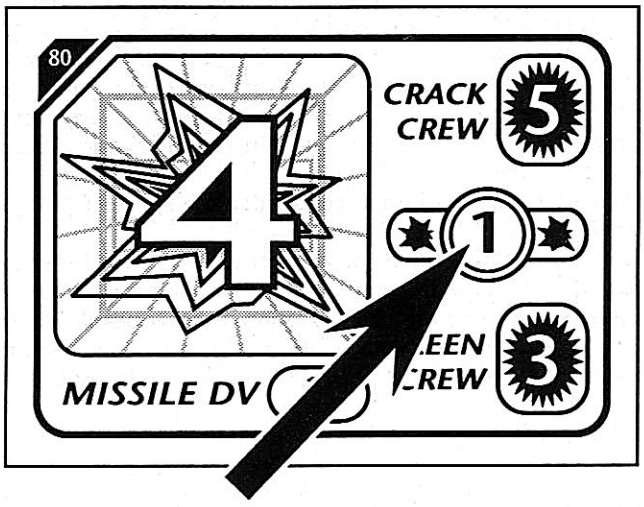
Base Difficulty: The rules below give specific details on the calculations of difficulty in each specific area, but all tasks begin with a base difficulty to which additional difficulty modifiers (often shortened to Diff Mods) are applied, based on specific circumstances. If the task is an absolute difficulty task, its base difficulty is specified in the rules (and repeated on the reference chart). If it is a ranged task, the range at which the task is attempted determines the base difficulty level. Each sensor, jammer, and weapon in the game has a listed range, which is its short range. Medium range is twice short, long is twice medium (i.e., four times short), and extreme is twice long (i.e., eight times short). Base difficulties at these ranges are given in the accompanying table.

Difficulty Level by Range

Range		*Difficulty*
Short		1
Medium	(2×Short)	2
Long	(4×Short)	3
Extreme	(8×Short)	4

Difficulty Modifiers: After the base difficulty level has been determined, difficulty modifiers (Diff Mods) increase or decrease the difficulty of the task. These Diff Mods are explained in the rules covering individual tasks and are summarized on the play aid card. Plus Diff Mods add to the difficulty level, making the task more difficult, while minus Diff Mods subtract from the difficulty level.

Reading the Card: Once the difficulty level of the task has been determined, turn a card and read the result. If the difficulty level is greater than 5, the tasks may not be attempted. Even if the difficulty level of the task is less than 1, a card is still turned. The central field of the card gives the card's success number. If the success number shown is equal to or greater than the task difficulty level, the task succeeds. If it is less than the difficulty level, the task fails.



For example, a medium range task with no Diff Mods has a difficulty level of 2. If a 1 is turned the task attempt fails, while if a 2 or higher is turned it succeeds.

Miss: If a "Miss" card is turned, the task attempt fails, even if the difficulty level was less than 1.

Bull's-eye: If a "Bull's-eye" card is turned, the task attempt succeeds.

Outstanding Success: Many tasks have additional beneficial effects from an Outstanding Success result. An Outstanding Success in fire combat, for example, causes double damage.

Two types of cards result in Outstanding Success. First, any "Bull's-eye" card is an Outstanding Success. Second, high-value cards can generate Outstanding Success. Cards with a value of 5 result in an Outstanding Success on tasks with a difficulty level of 2 or less, and cards with a value of 4 result in an Outstanding Success on tasks with a difficulty level of 1. This is noted in the Outstanding Success field of the card (see example below).

Crew Quality: Part of the card deals with success levels when different quality crews man the firing or sensing vessel. These values are used only when playing with the Crew Quality advanced rules (page 18).

Missile Damage: The missile damage field of the card is used to determine the damage levels of missiles. See the Missiles rule (page 12).

SEQUENCE OF PLAY

Each turn of play in **Battle Rider** is broken down into several subturns, called phases, to organize the number of activities that must be conducted each turn. Phases are always conducted in the same order. If, in a later phase, a player remembers something that he meant to do in an earlier phase, it is too late, as the decisions made in each phase affect the decisions in the phases that come later.

Initiative Phase
Operations Phase
Missile Movement Phase
Missile Attack Phase
Turn Record Phase

Initiative Phase

Players turn cards to determine initiative. Each player turns a card and the player whose card has the highest card ID number has the initiative. The player without the initiative launches and/or recovers ordnance, drones, and battle riders (see the Launching rule, below) and reconfigures task forces. After this is done, the player with the initiative does the same.

Reconfiguring task forces means that vessels in a task force may be divided into two or more smaller task forces, and vessels in several different task forces in the same hex may be switched between task forces or combined into fewer larger task forces. However, vessels may only switch from one task force to another, and task forces may only be combined, if both task forces have exactly the same vector (see Movement, below). Also, no task force at the end of the Initiative Phase may have more vessels in it that are allowed by the owning player's Fleet Tactics rating.

Operations Phase

In the Operations Phase, players take turns conducting operation rounds until one player has conducted operations with all of his task forces. The opposing player then conducts operations with all of her remaining task forces.

In each operation round, a player conducts all operations with any one of his task forces. Any task force desired may be used, but each task force may conduct operations only once per game turn.

All ships in the task force conduct all activities, and do so in any order desired. However, all must conduct each activity simultaneously. That is, the task force may fire and then detect, then move, or move and then fire and then detect, but all ships must make the same choice, conducting all fires at the same time, all detection attempts at the same time, and all movement at the same time. The following activities may be conducted in each operation round by each task force, in any order desired:

Move: First, determine whether the ships of the task force will expend Gs on maneuver and/or evasion. If so, place a Thrust marker in the hex with the task force. If the task force is maneuvering, the Projected Endpoint marker of the task force is moved (see the Movement rule, below). If the task force successfully evades, place an Evade marker in the hex.

All ships in a task force must spend the same number of Gs on maneuver and evasion, even if they have different G capabilities.

Detect: First, adjust status of sensors, if desired. (Place or remove Active Sensor marker, place or remove Passive Array marker.) Next, make any detection attempts desired against enemy task forces. See the Detection rule (page 6).

Fire: Ships may only fire at enemy vessels which have been detected (are on the map). First, turn a card to determine if the firing ship has a fire control lock. If so, then turn one card for each firing weapon to see if the weapon hit.

Missile Movement Phase

All missiles move according to the rules of missile movement. Players take turns moving missile spreads, with the player without the initiative moving the first missile spread, until all Missile Spread markers have moved. See the Missiles rule (page 12) for an explanation of the particulars of missile movement.

Missile Attack Phase

All defensive fire against missiles is resolved, and then all surviving missiles attack targets in their hex. All of the defensive fire by one target task force is resolved, and then all of the missile fire at that task force is resolved, before any fire by or at another task force is resolved. Although fire by and at task forces is conducted in order for ease of play, all fire in the Missile Attack Phase is considered to be simultaneous. In other words, ships destroyed or disabled by missile fire early in the phase may still control missile spreads attacking enemy targets later in the phase.

Turn Record Phase

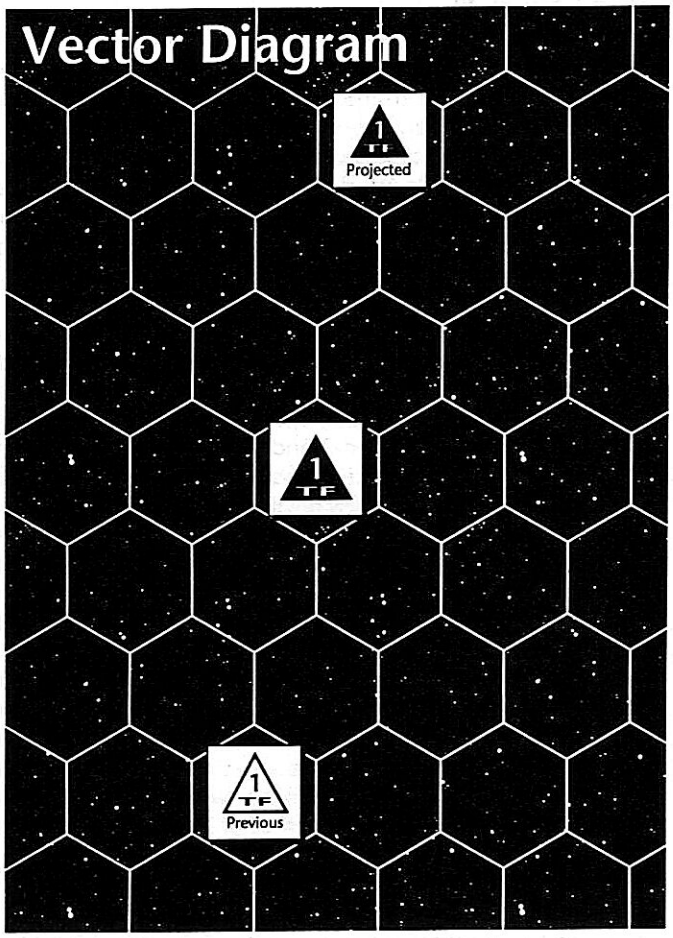
This marks the end of a complete game turn and is a time to take care of certain administrative tasks. All White Out-1, Circuitry Overload-1, and Temporary Damage-1 markers are removed. All White Out-2, Circuitry Overload-2, and Temporary Damage-2 markers flip to the 1 side. All task forces reposition their Projected Endpoint and Previous Position markers as detailed in the Movement rule.

LAUNCHING

Ships can launch and recover battle riders that they are carrying as well as missiles and sensor drones. This takes place during the Initiative Phase of the turn. Battle riders when launched may either become part of the launching ship's task force or form one or more additional task force in the same hex. Missiles are always represented by a Missile Spread marker, placed "undetected" side up. All newly launched battle riders and missiles have the same vector (see Movement rule, below) as the vessel they were launched from.

A ship may (but need not) launch all of its battle riders and/or missiles and/or drones in a single turn.

To recover battle riders, both the tender and the rider must be in the same task force.



Each tender may only carry the battle riders designed for it. In this game, the following tenders carry the following battle riders:

Tender	*Rider*
Triumph	Gallant
Cleon	Admiral
Maggart	Manticore

MOVEMENT

Battle Rider uses a realistic system of vector movement. Spacecraft move through space due to thrust and inertia. Once a spacecraft has expended thrust to move it in a certain direction, it will continue to coast in that direction forever, unless another force acts upon it, usually meaning until it expends thrust to change its course or speed. A spacecraft's course and speed are called its vector. On Earth, we rarely see pure examples of vectors, because moving objects are acted on by so many other forces such as friction with the ground or air, aerodynamic lift, and gravity. Our intuitive experience tells us that moving objects tend to slow down and stop, and that it's difficult to keep things moving. However, that is only true in the limited area of our planetary frame of reference. In fact, all objects are in motion and remain that way, coasting along at quite high speeds through empty space. Although it might initially seem strange to players who have not played vector games before, it is that reality which **Battle Rider** portrays.

Vectors: A vector is a representation of directional movement. In the game, each ship's vector is represented by its current position and either its former position or Projected Endpoint marker. At the beginning of each turn, a task force's vector is represented by the position of the task force itself and by a task force Projected Endpoint marker. At the end of each turn, a task force's vector is represented by the position of the task force itself and by a task force Previous Position marker.

In the Turn Record Phase of the game turn, the player places the task force's new Projected Endpoint marker on the map and then removes the Previous Position marker. The Projected Endpoint marker will have the same relationship to the Task Force counter as the Task Force counter does to the Previous Position marker. (See illustration above.)

Movement: Each task force begins each game turn (including the first) with a vector as described above. During the Operations Phase, the player will move the task force by replacing the Task Force counter with a Previous Position marker, moving the Task Force counter to the hex containing the Projected Endpoint marker, and then removing the Projected Endpoint marker from the map. Prior to movement, however, the player may alter the position of the projected endpoint by means of maneuver.

Maneuver: During the Operations Phase of each game turn, all players make decisions concerning the movement of their vessels. Each vessel maneuvers by firing its maneuver drive thrusters to change its vector. The power of a craft's thrusters is expressed in Gs of thrust (each of which represents the force of 1 G acting for a period of 30 minutes, or one game turn). Each vessel may spend Gs up to its G-rating on maneuver (to change its vector), evasion (to thwart potential incoming fire), or a combination of the two. Each craft's G-rating is listed on the back of the counter.

Each G of thrust spent on maneuver allows the player to move the projected endpoint of the task force one hex in any direction.

Any ship that does not use its maneuver drive to change its vector during the Operations Phase simply continues to execute the same already existing vector each and every Operations Phase until it is acted on by an outside force (such as the gravity of a large body), or until it exits the map.

Whenever a task force expends 1 or more Gs to maneuver (change its projected endpoint), place a Thrust marker in the map hex with the task force. This Thrust marker is placed on the one hexside which is closest to being in exactly the opposite direction from which the Projected Endpoint marker was moved. If two hexsides are equally close, the opposing player decides which hexside the marker is placed on.

Evasion: Vessels may also expend Gs on erratic, evasive maneuvers in an attempt to throw off enemy sensor and fire tasks, but the total number of Gs spent on maneuver and evasion combined may not exceed the vessel's G-rating. All ships in the task force must spend the same number of Gs on evasion, and one card is turned to determine the success of the entire task force. An evasion attempt has a base difficulty level of 5, but the task is reduced one level of difficulty (–1 Diff Mod) for each G-turn that is spent for evasion. For example, a ship with a G-rating of 5 that spent 3Gs on maneuver and 2 on evasion would have an evasion difficulty level of 3.

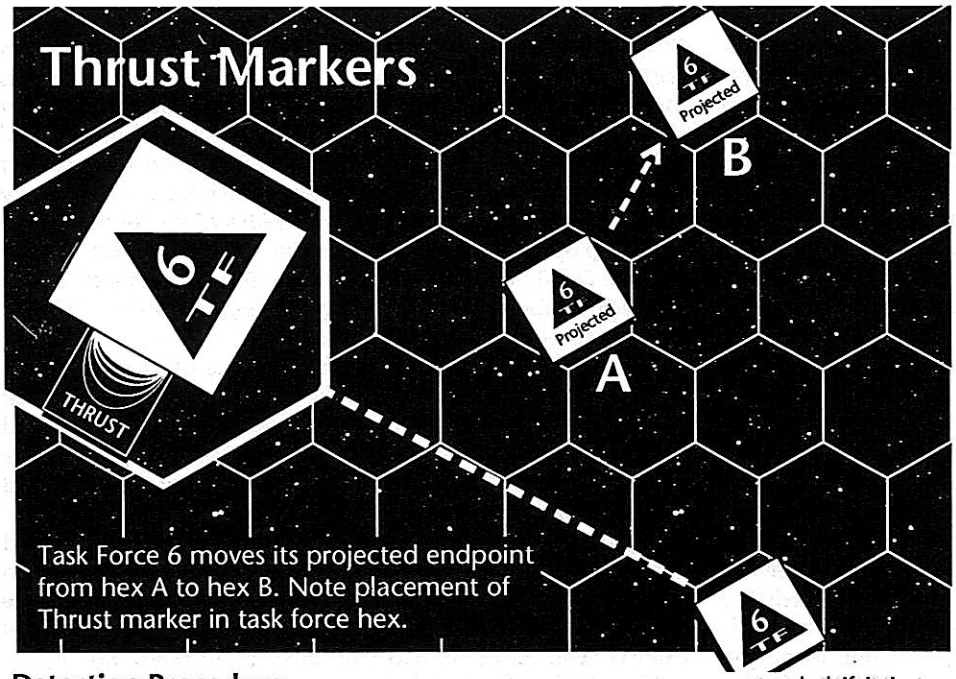
One card is turned for evasion during the operation round of the task force. If successful, an Evade +1 marker is placed on the task force. If the card turned indicates an Outstanding Success, the Evade +2 side of the marker is placed on the task force. If the attempt fails, there are no adverse affects (except for the waste of maneuver Gs).

Evasion results apply to all sensor and hit tasks directed against the task force for the rest of that turn and all of the next turn until its next operations round.

Because of the fragility of the structure, no vessel with a folding passive sensor array extended may burn Gs in a turn for evasion. (See Detection, below, for an explanation of folding passive sensor arrays.)

Movement of Dummy Task Forces: Each dummy task force can spend an unlimited number of Gs on maneuver and evasion each turn. (Of course, very large G expenditures will give away the fact that it is a dummy task force and defeat its purpose.)

DETECTION



Detecting an unidentified or known enemy target is the single most crucial step in space combat. Until detected, the exact nature of the target is not known. The crew of a starship may be well aware that "something is out there" based on ghost images, thermal hot spots, or flashes of returns on active sensors, but detection is required to identify the target, and more importantly, to do something about it.

At the start of play, all spacecraft are unknowns, whether they are large starships or sensor drones. For this reason, only the Task Force counter is placed on the map until an opponent detects them. The Task Force counter is moved normally using the movement and maneuver rules. This represents the tell-tale indications of something out there that can invite a detection attempt.

Detection attempts are made by spacecraft during the craft's operation round. Once a successful detection attempt is made, the detected spacecraft are placed on the map along with the Task Force counter (which is still required for movement purposes). Once detected, the spacecraft remain on the map for the rest of the scenario.

Types of Sensors: There are two broad types of sensors in the game—active and passive. Active sensors detect targets by sending out pulses of energy, such as radio waves or lasers, which then bounce off their targets and back to the sensor. The time that it takes the pulse to return, the shift in frequency of the pulse, etc., can be used to determine the distance and direction of the target, its motion relative to the sensor, etc. The two major drawbacks of the active sensor are that it broadcasts its own presence by filling space with pulses of energy, and that it requires a lot of power to generate pulses powerful enough to bounce back from very distant targets.

Passive sensors do not betray themselves by emitting energy; rather, they detect targets by sensing the energy given off by those targets. Passive sensors are typically less effective than active sensors in terms of absolute range, but are more tactically useful for ships that wish to remain unnoticed.

Task Force 6 moves its projected endpoint from hex A to hex B. Note placement of Thrust marker in task force hex.

Detection Procedure

Most ships have both an active and a passive sensor, each with different ranges of effectiveness. Once the scenario begins, players may begin to make detection attempts using any of the sensors available to them. Detecting a target is a task with the basic difficulty determined by the range of the target from the sensor, using the sensor range printed on the back of the ship counter. For example, a sensor with listed ranges of 5 would have a basic difficulty of 1 at 0-5 hexes, 2 at 6-10 hexes, 3 at 11-20 hexes, and 4 at 21-40 hexes. Detection could not be attempted beyond 40 hexes. This basic difficulty level can then be modified up or down by other factors as explained below.

All detection attempts are made during the task force's operation round. Each ship may use any or all of its sensors, and may make as many detection attempts as desired, with the limitation that no sensor may attempt to detect the same target (task force) more than once in the same operation round.

Each detection attempt is made against the craft in a task force which is easiest to detect. If successful, the detecting player may attempt to detect the next easiest craft, and so forth, until the player either fails in a detection attempt or determines that there are no additional undetected ships in the task force. This is done by detecting the "sensor shadow" of the task force.

Sensor Shadows: All task forces have a sensor shadow; task forces with no ships in them consist solely of a sensor shadow. The sensor shadow of a task force is treated as a size 0 spacecraft. If a detection attempt against the sensor shadow is successful, the detecting player is told that there are no further ships in the task force; if it is unsuccessful the detecting player is told only that.

A task force with no ships in it (usually a dummy task force, although it could be a task force in which the ships have all been detected and destroyed) is removed from play after its sensor shadow is detected.

Example: The Blue player attempts to detect the ships in Red Task Force 1 (RTF-1). Unknown to the Blue player, RTF-1 consists of only one ship. Blue's first detection attempt is against the easiest target in the TF, which is the ship. It is successful, and so Blue is allowed another detection attempt at the next easiest target. Since the only remaining undetected target is the sensor shadow, the Red player gives the Blue player the Diff Mods for this. The attempt is unsuccessful, and so the Blue player does not know whether there are additional Red ships in the task force. (Had the attempt been successful, the Red player would announce that there are no other ships present.)

In combat, the Red ship is destroyed, but the task force remains in play until the Blue player detects its sensor shadow.

Sensor Status: Before any detection attempts are made, the player decides which sensors each vessel in the task force will use.

Active/Passive: Players decide for each ship whether it will use active or passive sensors, or both. Vessels which have gone active are easier to detect by vessels equipped with direction finders or passive EMS sensors, and so the owning player places an Active marker on each vessel that uses its active sensor. This marker remains in place until the next operation round for that task force.

Folding Sensors: Some vessels are equipped with passive sensors that are noted on the counter back as being folding arrays. Passive sensor ratings printed in brackets are folding arrays. These sensors have large, synthetic aperture collection areas that must be extended on the ends of pylons and struts in order to be used. The passive sensor must be extended if it is to attempt a lock, as it cannot function when retracted. However, the greater target area presented by a vessel with an extended passive array makes it a better target for enemy *active* sensors. Each ship with a folding array must also make an extend/retract decision at the start of each Operations Phase. A marker is also provided for this purpose. On the Extended side, the marker shows a front view schematic of a ship with its array deployed, and the notation "–1 vs. Active." On the Retracted side is the notation that no locks are possible with the passive sensor.

Because of the fragility of the folding struts, no vessel with its folding array extended may burn any Gs in a turn for evasion.

Additional Difficulty Modifiers

The following conditions and circumstances modify the basic difficulty level based on range:

Going Active: A ship which has gone "active" becomes easier to detect for ships equipped with passive sensors. Any ship using passive sensors applies a –1 Diff Mod to detection attempts against an active target.

Target Size: The size of the target is a universally applicable modifier which applies in all sensor and fire tasks. The size modifier for each vessel is printed on the counter back.

Target Maneuver: The basic *passive* detection difficulty levels assume that the target is expending some energy (and hot reaction mass) to maneuver. Thus, a target which has spent any Gs at all in the turn adds no Diff Mod to the passive detection task attempt (except in the case of stern on—see next paragraph). If the target has expended no Gs for any purpose in the current turn, passive detection is one difficulty level harder (+1 Diff Mod). If the target is in "powered down" mode with its systems off-line and its power plant reduced to only a trickle of power, the passive detection is raised by two difficulty levels (+2 Diff Mod).

On the other hand, if the target is expending Gs of thrust and is presenting its stern (and therefore its hot exhaust) toward the sensor, the passive detection is reduced by three difficulty levels (–3 Diff Mod). Trace a line from the detecting ship to the target task force (traced from center of hex to center of hex). If that line crosses the hexside of the target task force which has the Thrust marker on it, the target task force is "presenting its stern."

Target Evasion: If the target task force has an Evasion marker on it, the appropriate addition is made to the difficulty level (+1 or +2, depending on the marker).

Electromagnetic Masking (EMM): Ships which are equipped with electromagnetic masking (EMM) packages reduce the effectiveness of active and passive sensors which are used against them. EMM not only disguises a vessel's passive (heat) signature, it also includes the use of stealthy materials to reduce the echo of active sensor energy, and so EMM on the target provides a +1 Diff Mod for both active and passive detection attempts.

Ships with EMM have the notation "Msk" in the sensor field of the counter back.

Jamming: Vessels may be equipped with jammers which allow them to attempt to jam enemy *active* sensors. These jammers are deceptive jammers, and are different from the area jammers discussed immediately below. Deceptive jammers do not attempt to blot out enemy sensor energy, but deceive enemy sensors by sending back false echoes that fool the enemy sensor about its target's true location/heading, etc.

Jamming tasks, like other ranged tasks, are based on the range in hexes from the jammer to the target of the jamming attempt, as indicated on the ship counter. Additional modifiers to this basic difficulty level are based on tech level (TL) differences between the sensor and the jammer. For each TL that the sensor exceeds the jammer, the jamming task is increased one level in difficulty (+ Diff Mod). For each TL by which the jammer exceeds the sensor, the jamming task is decreased one level in difficulty (– Diff Mod).

A separate task card is turned for each enemy active sensor that the player attempts to jam. The decision to jam is made separately each time an active sensor detection attempt is made, and the jamming card is turned immediately before the detection task card is turned. Success in the jamming task indicates that the opposing sensor is jammed, and attempts its sensor task at one difficulty level higher (+1 Diff Mod). Outstanding Success means that it must attempt at *two* difficulty levels higher (+2 Diff Mod).

A jammer-equipped ship may use deceptive jamming to raise the difficulty level of any detection attempt directed at the task force to which it belongs, including attempts to detect the task force's sensor shadow. If several ships in a task force are equipped with jammers, only one may be used per detection attempt. Ships from one task force may not use their jammers to aid ships from another task force, even if they are both in the same hex.

Area Jamming: Some ships may be equipped with jamming drones. These drones are fitted with energy-intensive broad-band noise jammers. Area jammers are not finesse devices like the above deceptive jammers. Area jammers attempt to defeat enemy sensors merely by drowning out their signals with more powerful electronic noise. The area of affect of an area jammer is the hex it is in plus the six hexes surrounding it. Any sensor "line of sight" (i.e., the straight line traced from the center of the sensor's hex to the center of the target hex) that passes through this area of effect has its difficulty increased by one level (+1 Diff Mod). In the example at right, a sensor in hex A is attempting to detect targets in hexes B, C, and D. Because the lines of sight A-B and A-C pass through the area jammer's area of effect, those sensor tasks are increased by one difficulty level. The sensor task A-D is unaffected by the area jammer.

If the line of sight passes through the overlapping areas of effect of more than one area jammer, the difficulty is increased by one level per area jammer.

Because area jammers are typically mounted on drones, the areas of effect will move from turn to turn. Area jammers may be turned on and off by the owning player at will. The decision is made during the operation round of the task force containing the jammer, and remains in effect until the next operation round of that task force.

Any craft that is carrying an operating area jammer makes itself an easy target for passive detection. Use the rule above for going active, except that the Diff Mod is –2 .

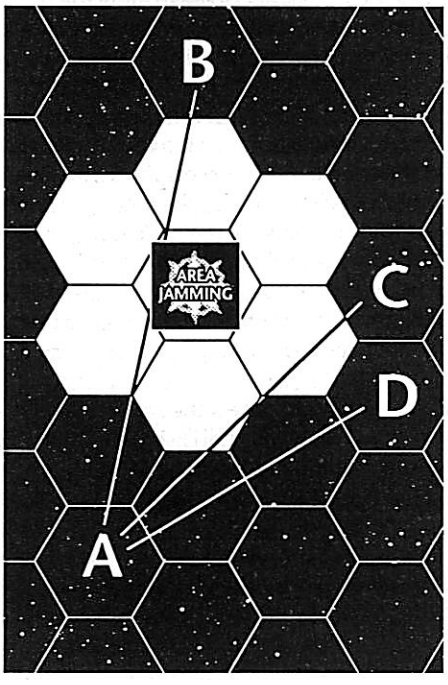
Missile Detonation White Out: When a missile detonates (see the Fire and Combat rules below for a fuller description) in a hex, its nuclear explosion creates a temporary white out effect that makes the use of passive sensors more difficult. Any passive sensor detection attempt into that hex (this does not include attempts whose "line of sight" merely pass through the hex) is one difficulty level higher (+1 Diff Mod) for each missile detonation in the hex. This is easily represented by replacing each detonated missile counter with a White Out marker, and adding up the Diff Mods of the White Out markers in the hex.

White Out-1 and White Out-2 markers have the same effect; the different numbers are merely means of keeping track of when the marker was placed and when to remove it.

"Terrain" Effects: Certain objects in space can also affect the difficulty of a detection attempt. There are two types of interstellar terrain in **Battle Rider:** planets and asteroids, which are represented by counters placed on the map. For a complete discussion of the use of planets and asteroids in **Battle Rider**, see the Advanced Astrographics rule (page 17).

Any craft that is in the same hex as a Planet counter or an Asteroid counter is given the benefit of the doubt that it is maneuvering to take advantage of the object's bulk and passive signature to obscure its own. All sensor tasks attempted against the target are one level more difficult vs. passive and active sensors (+1 Diff Mod).

Black Globes: Black globes are very sophisticated, very rare, and very expensive defensive devices that create a sphere around the defended vessel. Because these screens are so rare, they are not discussed here, but are dealt with in the advanced rules (page 17).



Multiple Effects: The effects described above are all cumulative.

Procedure for Resolving Detection Attempts

The procedure for resolving sensor lock attempts divides the task between the sensing player and the target player, where each is responsible for calculating certain Diff Mods. This not only eases the workload and keeps both players interacting, but also is intended to ensure that information about targets is not revealed to an opponent during the course of resolving an unsuccessful sensor task.

Always start with easiest target in the task force to detect. Then go to harder and harder targets, until a task fails or all targets are detected.

Detecting Player: The player making the detection attempt indicates the target of the attempt and announces to the target player the type of sensor being used: active or passive. If using an active sensor, the detecting player must indicate where the scan is coming from.

When announcing these scans, the detecting player is responsible for calculating the following items which need not be told to the target player.

- Basic difficulty level of the sensor lock attempt based on range (the sensing player must also be careful to not use folding arrays which are in retracted status).

•Diff Mods based on sensor line of sight passing through an area jamming area of effect (+1 Diff Mod per area).

•Diff Mods based on Planet or Asteroid counter in the target hex (+1 Diff Mod).

•Diff Mods based on White Out markers in the target hex (+1 Diff Mod per marker).

•Diff Mods based on target having gone active (–1 Diff Mod for passive detection).

•Diff Mods based on target being a source of area jamming (–2 Diff Mod for passive detection).

•Diff Mods based on the target's maneuver that turn (0, +1, +2, or –3 Diff Mods).

•Diff Mods based on the target's successful evasion attempt that turn (+1 or +2 Diff Mods).

The player aids card recapitulates these items to assist the player in keeping track of them. These items yield one cumulative, net Diff Mod.

Target Player: Once told that his or her ship is the target of a sensor lock attempt, the target player is responsible for reporting to the sensing player the net Diff Mod based on the following criteria.

First, if the sensor attempt is using an active sensor, the target player must decide whether to try to jam the sensor. If so, the target player must announce to the sensing player that the target is jamming and announce the difficulty level of the attempt. The jamming task determination is made by turning a card. The target player then includes the correct jamming Diff Mod in the net Diff Mod reported to the detecting player.

The target player is responsible for the following items:

•Diff Mods based on a successful jamming attempt vs. the sensor (+1 or +2 Diff Mods).

•Diff Mods for spacecraft target size and EM masking packages (printed on the spacecraft counter back) (+1 or +2 Diff Mods for masking).

•Diff Mods for difference in tech levels of the detecting sensor and the target craft. Add the difference in tech levels if the target craft's tech level is higher; subtract the difference if it is lower.

•Diff Mods based on passive array extended (–1 Diff Mod for active detection).

•Diff Mods based on black globe generators (Diff Mod varies with use).

The player aids card presents these items to assist the player in keeping track of them.

Resolution: The target player announces the target net Diff Mod to the detecting player, who then combines it with the sensing net Diff Mod to get the final net Diff Mod. The sensing player then applies this modifier to the basic difficulty level based on range. A card is turned and the the success level compared to the difficulty level.

If the attempt is a success, the target ship is placed on the map in the same hex as the Task Force counter.

Outstanding Success has no additional effect when part of a sensor task.

FIRE AND COMBAT

Fire of virtually all weapons on a vessel takes place during that vessel's operation round. Ships may fire before or after movement, and ships in a task force may split their fire, so that some fire before movement and some after. A ship may itself split its fire, firing some weapons before and some after movement.

Larger ships (those with a size code of –2, –3, –4, or –5) may fire all of their beam weapons in the Operations Phase and then fire all of them again (except for the spinal mount) in the Missile Attack Phase. Smaller ships (those with a code of –1 or more) may fire their weapons in either one phase or the other, but not both. A small vessel may choose to hold fire with its anti-missile lasers to fire later in the Missile Attack Phase. If so, place a Lasers Hold Fire marker on the vessel. If virtually all small vessels of a side are holding fire with their lasers, it may be easier to simply mark those which fired. In this case, use the reverse side of the marker, which is labeled Lasers Fired.

Hits may be negated or reduced in effect by shipboard defenses which include active defenses like sandcasters, and relatively passive defensive screens and armor.

Weapons Types

There are three main types of weapons used in space combat: lasers, particle accelerators, and meson guns. Each of these has differing characteristics.

Lasers use focused beams of coherent light to impart energy to enemy targets over a very small area. Relative to other long-range beam weapons, lasers have good penetration performance, but generate less explosive force and damage. The missiles used in **Battle Rider** are specialized high-performance laser carriers, which power these lasers by detonating a nuclear explosion, thereby destroying itself. All weapons designated L are lasers.

Lasers are little affected by ship armor, but can be blocked by sandcasters and black globes.

Particle accelerators accelerate subatomic particles—almost exclusively neutral atoms such as hydrogen—to very high speeds at enemy targets. These have less penetrative ability than do lasers, but generate a much greater explosive force. Unlike lasers, particle accelerators require long accelerator tunnels, and so most are built as spinal mount weapons, running the entire length of the ship. All weapons designated P are particle accelerators.

Particle accelerators can be blocked by ship armor, sandcasters, and black globes.

Meson guns also accelerate subatomic particles at enemy targets. But in this case the particle is a meson, which does not interact with matter, and therefore passes through all objects without resistance. However, the meson has only a short life, after which it decays into other more destructive particles. By accelerating the meson to relativistic speeds, its subjective passage of time slows, and its decay is delayed. By timing the decay to occur as a group of mesons pass through an enemy ship, powerful explosions can be created within enemy targets without having to penetrate the armor.

Meson guns may only be blocked by meson screens and black globes.

Fire Eligibility

In order to be eligible to fire its weapons at a target, a ship must have a fire control lock on that target. A fire control lock is obtained immediately before firing the ship's first weapon. It is a task performed exactly like detection, using all of the same Diff Mods as detection, but with two additional conditions:

1) Fire control locks may only be attempted against targets which have already been detected (i.e., are physically placed on the map).

2) Fire control locks are conducted with an additional –1 Diff Mod.

If the task is successful, the ship my fire any or all of its weapons at the target. If it fails, no fire at that target is allowed. There is no additional effect from Outstanding Success.

No single weapon may fire more than once in a phase. No weapon rendered inoperative by damage may fire.

Hit Procedure

As with sensor lock and communications tasks, obtaining a hit on a target is a task whose basic difficulty level is based on the range to the target. Basic difficulty levels by range are given on the table at the top of page 10 and are summarized on the reference card.

Difficulty Level by Range

Range		*Difficulty*
Short		1
Medium	(2×Short)	2
Long	(4×Short)	3
Extreme	(8×Short)	4

Additional Diff Mods are applied to this basic level. These are based on target size, target evasion, absolute range, overpowering the weapon, and the use of advanced fire control systems.

Target Size: The target's size provides a Diff Mod that is used when resolving all fire tasks. This Diff Mod is printed on the counter backs.

Target Evasion: Target evasion works in the hit procedure exactly as it does in the sensor lock procedure, detailed above. Remember that the evasion attempt is made in the operation round once for the entire turn, with that result applying to all sensor and hit tasks in the turn.

Absolute Range: The basic difficulty level listed with each weapon is based on that weapon's own fire control system. This difficulty reflects the weapon's ability to accurately direct the weapon's fire at a given point in space over a certain range. However, the range to the target has another affect on hit probability.

When a weapon fires at a target at range R, it is using tracking data that has come from the target (infrared radiation, reflected radar or ladar beams, etc.) over that range R at the speed of light. Assuming the weapon is a laser, it arrives at the target at the speed of light, again passing over the distance R. The time elapsed from when the tracking information left the target and the arrival of the laser fire back at that target is the amount of time that it takes light to travel the distance 2R. If R is a large number, say 300,000 kilometers or one light-second (10 hexes in **Battle Rider** scale), the elapsed time would be two seconds. The target can have moved a long way in two seconds, and a tiny degree of error magnified over 300,000 kilometers makes it very easy to miss that target.

To account for this additional difficulty, take the range to the target in hexes, divide by three, and drop fractions (or see the accompanying table). The result is the number of difficulty level increases (+ Diff Mods) applied to the to hit task.

Diff Mods from Absolute Range

Range in hexes	*Diff Mod*
0-2	—
3-5	+1
6-8	+2
9-11	+3
12-14	+4
15-17	+5
18-20	+6
21-23	+7
24-26	+8
27-29	+9
30-32	+10
33-35	+11
36-38	+12
39-41	+13
42-44	+14

Overpowered Weapons: All weapons can draw more than their normal rated power. Although this does not increase the energy in each shot, it enables the weapon to fire a broader pattern of shots, thus increasing the hit probability.

All weapons can be fired at –1 or –2 Diff Mods by overpowering. Those weapons with overpowering capability designed in, and with sufficient excess power-generating capability, have their overpowering Diff Mods appended in parentheses after the weapon type designator.

For example, a typical meson gun spinal mount might be described as:

M10:6-4-3-2

If designed for routine overpowering to the –2 Diff Mod level, it would be described as:

M(–2)10:6-4-3-2

Weapons designed to be overpowered to the –1 or –2 level may always fire with those Diff Mods without penalty. Weapons not designed with this capability suffer two limitations: power and circuitry.

Power: In order for the ship to fire any weapons at –1 Diff Mod, the ship must forego use of 1G of acceleration that turn. In other words, its total of maneuver and evasion Gs used must be one less than its total G-rating. This allows the ship to fire any and/or all of its weapons at –1 Diff Mod. In order for a ship to fire any weapon at a –2 Diff Mod, the ship must forego use of 2Gs of acceleration that turn, which allows the ship to fire any and/or all of its weapons at a –2 Diff Mod.

Circuitry: Ships not designed to fire at higher power levels may experience firing circuitry overload. A player announces the intention to overpower one or more weapon on a ship before any fire is resolved from that ship and then makes the task attempt to avoid a circuit overload. Avoiding circuitry overload is a task with a fixed difficulty level of 2, and with a +1 Diff Mod applied for every weapon overpowered that turn in excess of the first one. Note that this attempt is made once for the ship, not separately for all weapons on the ship.

If the ship fired at a –1 Diff Mod above its normal capacity, the player turns one card. (This is the case if it fired at a –1 Diff Mod and was not designed for any overpowered fire, or if it fired at a –2 Diff Mod but was designed only for –1 overpowered fire.) If the ship fired at a –2 Diff Mod above its normal capacity, the player turns two cards and must succeed on both attempts for the overall task to succeed. If the task succeeds, the ship fires normally; if it fails, the ship suffers a circuitry overload result. Place a Circuitry Overload-2 marker on the ship.

Ships that suffer a circuitry overload result may not fire any beam weapon for the remainder of that turn and all of the next turn. A ship with overloaded circuits may still launch missiles and use screens.

Fire Control: Most warships are equipped with fire directors. A fire director allows the gunners to fire weapons with an improved chance to hit.

The difficulty level of a fire director-directed fire task is calculated the same as it would be for weapons without fire control. However, when calculating increased difficulty levels due to absolute target range and evasion, the fire director allows the gunner to ignore a certain number of + Diff Mods. The fire control rating of the ship is the number of + Diff Mods it may ignore *on every weapon fired in a turn.* In other words, a ship with a fire control rating of 6 could ignore 6 +Diff Mods on each shot it takes; it does not have to divide the 6 between separate shots.

Fire control may only *counteract* +Diff Mods that apply; it may not *reduce* a base difficulty level.

Resolution: Once the final difficulty level is derived, turn a card and resolve the task. Success indicates that the weapon hit. Outstanding Success indicates that the weapon hit and did double damage. (See Damage, page 11.)

SCREENS

Screens on the target vessel may be used to attack specific "hits" which have been scored. A hit, for purposes of this rule, is the damage caused by one weapon, even if that weapon causes more than one Damage marker to be drawn and placed on the target ship.

Each screen must be directed against a specific "hit," and all weapons firing against a specific hit must be allocated before any are resolved. Although more than one weapon may be directed against a specific hit, if one defensive weapon stops the hit, the others may not then be re-targeted against a different one, nor may additional defenses be allocated against a hit if previous defenses failed.

For each screen directed against a hit, turn a card to make a "screen save." *All screen saves have a base difficulty level of 2.* Diff Mods for different types of screens are detailed below and summarized on the game reference chart.

Sandcasters: Sandcasters fire cannisters of ablative crystals, commonly known as "sand." Each sandcaster contains a generator which creates a field which manipulates the location and shape of the cloud of crystals. At early tech levels, these fields are electromagnetic in nature, and require the use of magnetic sand. More advanced systems are able to supplement and then supplant the magnetic manipulation with gravitic manipulation, which allows the use of more effective non-magnetic crystals.

These clouds are placed in the path of incoming beam weapons, and cause the beam weapon to expend its energy burning through the cloud. The sandcaster operator uses laser warning sensors installed in the sandcaster to detect fire control locks and anticipate incoming beam fire.

Sandcasters may only be used against laser and particle accelerator hits.

Screen save tasks with sandcasters are modified one level up (+1 Diff Mod) for each two tech levels by which the firing beam weapon exceeds the sandcaster, or downward one (–1 Diff Mod) for each two tech levels by which the sandcaster exceeds the beam weapon's tech level.

A successful sandcaster "hit" on a laser or particle accelerator hit reduces its damage value by 1. On an Outstanding Success, its damage value is reduced by 2.

Each sandcaster can only be used against one hit per enemy operation round, but is available to fire again in later operation rounds and in the Missile Attack Phase. Thus it is possible for the coordinated fire of a large enemy task force to overwhelm the defenses of a ship, although several task forces firing at different times have less ability to do so.

Meson Screens: Meson screens project an energy field which interacts with incoming mesons, causing them to decay harmlessly outside of the vessel's hull. Meson screens may only be used against meson gun hits. A meson screen is not directed at a specific meson gun hit; instead, the ship's meson screen automatically protects it against all incoming meson gun hits that turn. As a result, there is no limit to the number of meson gun hits a single screen may protect against.

Screen save tasks with meson screens are modified with +Diff Mods equal to the firing meson gun's damage value (or twice its damage value if it scored an Outstanding Success on its hit task), and with –Diff Mods equal to the meson screens' screen value.

Success indicates that the meson gun "hit" does no damage to the vessel.

Dampers: Nuclear dampers are another form of screen, but are useful solely against missiles, and so are covered in the Missiles rule (see page 12).

Black Globes: These rare defensive screens are not normally encountered, so are discussed in the advanced rules, page 17.

DAMAGE

Once hits are obtained, and they have successfully made it through the target's defenses, determine what systems were damaged and how much actual damage was sustained.

Weapon Damage Performance

Weapons are listed with damage values that are used to calculate the amount of damage they do when they hit a target. These figures vary with range; make sure to use the correct numbers for the range at which the hit was scored.

Calculating Damage Value: The method used to calculate damage inflicted on a target differs depending on the type of weapon being fired. In all cases, if the weapon did double damage (due either to a Bull's-eye card or a Double Damage card), double the damage value before making any of the following calculations.

Lasers: When calculating the damage of a laser (including a missile), subtract the value of any sandcaster hits, subtract the target's armor value divided by 10 (dropping fractions), and add the target's size modifier to the weapon's damage value. (Since most ships have a negative value for a size modifier, adding this will have the effect of reducing the damage value of the weapon.)

Note that lasers have a very high ability to penetrate armor, and this is reflected in the game by dividing armor by 10 and dropping fractions. As no ships in this game have an armor value of 20 or more, as a practical matter it means that ships with an armor value of 10 or more subtract 1 from laser damage while ships with an armor value of 9 or less subtract nothing.

Partide Accelerators: When calculating the damage of a particle accelerator, subtract the value of any sandcaster hits and the target vessel's armor value (AV), and add the target's size modifier to the weapon's damage value.

Meson Guns: When calculating the damage of a meson gun, add the target's size modifier to the weapon's damage value and subtract the value of the defending meson screen.

Note that the meson screen value is only subtracted from the weapon damage value on a *failed* meson screen task attempt. On a successful task, the meson gun shot misses and causes no damage at all.

The meson screen value, when subtracted from the firing weapon's damage value, may never reduce the damage value to less than 0, provided it was greater than 0 after addition/subtraction of target size.

Determining Damage: If the weapon's final damage value is less than 0, it has no effect. If its damage value is exactly 0, draw one Damage marker and treat it as temporary damage (see below). If the damage value is 1 or more, this is the number of permanent damage results the ship suffers.

Temporary Damage: Draw one Damage marker and place it, along with a Temporary Damage-2 marker, on the ship counter. The effects of the damage last for the rest of the turn in which the damage was suffered and throughout the next turn. This represents a less severe version of the damage result in all cases except Ship Explodes results. If a Ship Explodes result is drawn, the target ship is still destroyed and permanently removed from play; replace it with a White Out-2 marker.

Permanent Damage: The weapon's final damage value is the number of permanent damage results the target vessel suffers. Draw this number of Damage markers from the cup and place them on the target vessel. Examine them and return any duplicates to the cup. If a Ship Explodes result is drawn, return all of the markers to the cup, remove the vessel from the map, and replace it with a White Out-2 marker.

In all cases, the Damage markers may be examined by the opposing player.

Damage Results: There are 12 distinct damage results possible.

Bridge Destroyed: The ship's bridge explodes, destroying all controls located there (including maneuvering, astrogation, sensors,

and fire directors) and killing or incapacitating the entire bridge crew. The ship is no longer capable of maneuvering, entering jump, jamming enemy sensors, detecting new targets, or operating screens (meson, damper, or black globe). Weapons may continue to engage targets, but attempt a sensor lock-on at one difficulty level higher (+1 Diff Mod). Ships equipped with an auxiliary bridge may shift control functions there beginning the following turn and so treat the first bridge destroyed result as temporary damage. (The second hit of this type suffered, however, will be permanent.)

Fire Control: Destroyed circuitry and power spikes disable the ship's fire control interface between weapons, sensors, and targeting processors. The ship may not fire any energy weapons, nor may it operate missiles. Ship's screens (sandcasters, nuclear dampers, meson screens) continue to operate.

Power Plant: The power plant is disabled and goes off-line. It may not be repaired or restarted for the duration of the scenario. The ship goes on auxiliary power/batteries. The ship may not maneuver, evade, jam hostile sensors, fire energy weapons, or operate any active sensors or screens (meson, damper, or black globe). The ship may fire missiles and sandcasters and operate passive sensors at +1 Diff Mod.

Sensors: Destroyed circuitry and power spikes disable all sensors. The ship may no longer jam hostile sensors nor make active or passive detection attempts. The ship may still attempt target fire control locks, but does so at +2 Diff Mod.

Life Support: The ship's life support has failed and the hull's integrity has been breached, and the crew must rely on their vacuum suits for survival. All tasks are conducted at +1 Diff Mod.

Ship Explodes: Liquid hydrogen and oxygen escape from shattered storage tanks, combine in the internal spaces of the ship, and explode, setting off a chain reaction with the ship's ordnance and power plant. The vessel is completely destroyed. Replace the ship counter with a White Out-2 marker.

Artificial Gravity: The ship's artificial gravity and G compensators fail. The ship may not spend more than 2Gs to maneuver in the same operation round, and may not evade at all.

Jump Drive: The ship's jump drive is disabled and the ship may not enter jump space.

Maneuver Drive: The ship's maneuver drive is disabled and it may not maneuver or evade.

Spine: The ship suffers serious structural damage that throws the vessel out of alignment. Any spinal mount weapons are rendered inoperative. In addition, the maneuver drive thrust line is no longer centered on the ship's axis of mass, and so any acceleration must be accompanied by constant attitude correction. For each G of maneuver or evasion thrust used, turn a card to test for tumble. Avoiding tumble is a task with a base difficulty of 2, with no Diff Mods. If the task attempt fails, place a Tumble marker on the ship. If 2 or more cards are turned which fail the attempt, place a Severe Tumble marker on the ship.

A ship tumbling (or tumbling severely) immediately becomes a separate task force and continues to tumble until the end of movement in its next operation round. The tumbling ship automatically corrects its tumble at the end of that movement, but may not maneuver or evade in the operation round in which it corrects its tumble.

So long as a ship has a Tumble marker on it, all tasks are performed with a +1 Diff Mod. So long as a ship has a Severe Tumble marker on it, all tasks are performed with a +2 Diff Mod.

Computer: Destroyed circuitry and power spikes disable the ship's data bus and information processing systems. The ship may not launch small craft or enter jump. All other tasks are conducted at one higher difficulty level (+1 Diff Mod).

No Effect: Damage control parties respond rapidly and bring all damaged systems back on line.

MISSILES

All missiles in **Battle Rider** are armed with nuclear-pumped X-ray laser warheads. Missiles maneuver to arrive in or near the hex occupied by the target. Once it is close enough to the enemy, the missile makes final targeting adjustments, then deploys a number of laser-generating rods, and detonates its nuclear warhead. The energy of the nuclear explosion creates high-energy (X-ray) photons within the rods, which are focused along the rods' lengths into X-ray beams which travel to the target, and do damage as normal lasers. Mere milliseconds after firing, the rods are themselves consumed by the nuclear explosion.

Ships which can launch missiles have the necessary game information recorded in the missile field of the counter back. This information always consists of the notation "Msl:" (indicating that the information refers to missiles) followed by two numbers, the second of which is in parentheses. The first number is the number of missile directors the ship has and the second number is the total number of ready missiles carried. The *Voroshilef*, for example, has 40 missile directors and 200 ready missiles.

BB Voroshilef-1
M(–2)6:12-10-6-4 –4
M(x2–2)4:10-6-4-2 TL-13
P(x2–2)10:10-10-10-6 FC:–6
L(x20–2)10:1-1-0-0 M:40(200)
A:16 P:8 J:16 Msk (SP) J3 G2
AV:12 AuxB —
MS:11 SC:30 D:5 182

The missile director value is the number of missiles which may be controlled in a turn. The ready missiles carried is the total number of missiles that the ship may fire throughout a scenario. A ship may launch as many missiles in a turn as the owning player desires (up to the total of ready missiles remaining).

Missiles moving on the map after launch are represented by Missile Spread counters. Each such counter represents all of the missiles fired by a ship in a single turn and with the same vector. If some of the missiles later change vector, a new Missile Spread marker will be placed on the map to represent them.

Missile Spread counters have a detected and an undetected, "Bogey," side. When launched, the undetected side is placed up. Missile spreads are detected as a whole, and have the detection characteristics of a single missile in the spread (target size code of +2). Once a spread is detected, the detected side is turned face up and all missiles in the spread are detected.

Types of Missiles

In the basic game only controlled missiles are used. These are missiles remotely piloted to their target from the launching ship. Semi-independent missiles are covered in the advanced rules (page 18). All controlled missiles have 12Gs of acceleration to expend in movement and have a target size code of +2.

Missile Roster

A missile roster is required to keep track of missile ammunition and the composition of missile spreads on the map. Either photocopy the sheet provided on page 30 of this booklet or use a blank sheet of ruled paper. Record missile spread information on the ruled side of the paper, and on the reverse record missile ammunition information. (This way you only have to deal with one sheet of paper.)

The missile ammunition side of the sheet should have the identity of each ship in play under your command which is equipped with missiles. Write the number of ready missiles after the ship identity (taken from the missile field on the counter or the scenario information, if different from normal availability). Leave room to make hash marks after the ship name to mark of missiles as they are fired.

The missile spread information side should be divided into four columns, labeled "spread," "composition," "G," and "ship."

Launching Missiles

Missiles are launched in the Initiative Phase of the turn. First the player without the initiative launches missiles, then the player with the initiative launches. Launching missiles is done in three steps.

1. Record Missile Spread: On the Missile Spread Sheet, write down the letter code of the Missile Spread counter used (in the "spread" column), the number and type of missiles in the spread (in the "composition" column), and the identity of the ship which fired the spread (in the "ship" column).

Write the number of Gs available to the missiles in the spread in the "G" column. This is the G-rating of a single missile. If missiles of different types are included in a single spread, the lowest G-rating is recorded in the "G" column.

2. Update Missile Ammunition: Mark off the appropriate number of missiles from the firing ship's supply on the missile ammunition side of the Missile Spread Sheet.

3. Place Spread Marker: Place the correct spread marker in the same hex as the task force which contains the firing ship. Place the missile spread's Projected Endpoint marker in the hex containing the task force's Projected Endpoint marker.

Detecting Missiles

Missile Spread counters have a detected and an undetected, "Bogey," side. When initially launched, they are place with their undetected side up, even if launched from a ship which has already been detected.

The opposing player may use sensors to detect missile spreads the same way that they are used to detect task forces. Missile spreads are detected as a whole, and have the detection characteristics of a single missile in the spread. Once a spread is detected, the Missile Spread counter is flipped to its detected side and the owning player must tell the detecting player how many missiles are in the spread (but need not tell what type).

Controlling Missiles

All missile control decisions are made during the Missile Movement Phase. Each player indicates, in turn, which missiles are being controlled and then moves those missiles. A ship controls its own missiles and may not control those launched by a different ship. If a firing ship is destroyed or suffers a fire control hit, remove all of the ship's missile spreads from play. The missile director value of the ship is the number of missiles which it may control in a turn.

Note that a ship can have more missiles in flight at one time than it can control. For example, a ship could launch a large number of missiles a few at a time, and maneuver them to a form a picket line in front of the ship. As it launched more missiles, the missiles that were already in position in the picket line would be allowed to go uncontrolled, and would coast along ahead of the ship, forming a screen until they were needed.

Moving Missiles

Players take turns moving controlled missile spreads in the Missile Movement Phase. All missiles in a spread execute the same move. If player wishes some missiles in a spread to move differently than others, then a new Missile Spread marker is placed in the hex (and a new Missile Endpoint marker) and the missiles of the original spread are divided between the two spreads.

Missiles maneuver by burning Gs of acceleration, just as do ships. The Missile Characteristic chart (on page 18 and on the Player Aid Card) lists the total number of acceleration Gs available to each type of missile, and this should be recorded on the Missile Spread Sheet. As many of these Gs may be expended in a single turn as desired. The number of Gs expended is the number of hexes the controlling player can displace the Projected Endpoint marker of the missile. After the Projected Endpoint marker is displaced, mark of the number of Gs expended on the Missile Spread Sheet, then move the missile spread to its projected endpoint, and then move its Projected Endpoint marker an identical number of hexes to show the new projected endpoint for the next turn. Flip the Projected Endpoint marker over to show that this missile spread has finished its movement for the turn.

If the straight line path of the Missile Spread marker from its starting position to its endpoint ends in or passes through a hex containing a target, the controlling player may declare that the missile spread is attacking that target. Only detected targets may be attacked; undetected missiles and task forces may not. Before moving the missiles, the declaring player must make a fire control lock task attempt from the controlling ship to the target. If this succeeds, the missile spread may attack; if it fails, the spread finishes its projected move without attacking.

If the missile spread will attack the target, place the missile in the hex with the target and then place the missile Projected Endpoint marker as if the target hex were the true final hex of movement. For example, if a missile had a straight-line vector of four hexes but stopped to attack a detected ship after three hexes of movement, the Projected Endpoint marker for the missile would be placed four hexes past the target hex. (This is important for calculating closing velocities, as explained below.)

Once all controlled missile spreads have moved, move all uncontrolled missile spreads. These move exactly like controlled missile spreads, except that they may not burn Gs and may not attack targets they pass or end the move with.

Defensive Fire at Missiles

Detected missiles may be fired at the same as any other detected target in the Operations Phase of the game. However, a special round of last-ditch defensive fire at attacking missiles takes place during the Missile Attack Phase.

All of the defensive fire by one target task force is resolved, and then all of the missile fire at that task force is resolved, before any fire by or at another task force is resolved. Although fire by and at task forces is conducted in order for ease of play, all fire in the Missile Attack Phase is considered to be simultaneous. In other words, ships destroyed or disabled by missile fire early in the phase may still control missile spreads attacking enemy targets later in the phase.

Note that during the Missile Attack Phase ships in a task force may only fire at missiles targeted against it; they may not fire at missiles attacking another task force, even if that task force is in the same hex.

Defensive fire by a task force is resolved in five steps:

1. Target Declaration: The missile-firing player declares the targets of the missiles in each missile spread. The missiles in each spread may be divided among the ships of a task force, but all of the missiles in the spread must attack a single task force. If a large number of missiles are involved, players will find it convenient to make a side note on scratch paper of how many missiles are attacking each ship from each spread.

2. Fire Control Lock: Each ship of the task force must obtain a fire control lock on any missile spread before it can fire at it. If the missile spread has already been detected, this is done normally (and receives the –1 Diff Mod for attempting a fire control lock). If the missiles are undetected, a fire control lock is normally not possible. In this case, however, the ship is allowed a normal detection attempt (without the –1 Diff Mod for the fire control lock attempt) and, if successful, has a fire control lock on the missile spread.

3. Beam Weapon Fire: Beam weapons can be used in a *de facto* defensive role to destroy missiles before they get close enough to fire, and takes place in the short period of time that the missile is deploying its laser rods and making adjustments for its final fire control solution.

Each beam weapon may fire at a single missile (not spread). If more than one beam weapon fires at a single missile, only one firing card is turned. The beam weapon with the best chance of hitting is used, and

each additional beam weapon firing provides a –1 Diff Mod (in addition to any other Diff Mods) to the fire. Any hit on a missile destroys it, and it is removed from play. A missile destroyed by hostile beam fire does not detonate, and so no White Out marker is placed in the hex.

4. Nuclear Damper Fire: Nuclear dampers are based on the manipulation of the so-called strong nuclear force which holds atomic nuclei together. By properly projecting this force onto incoming nuclear warheads, the damper can prevent the warhead from undergoing nuclear or thermonuclear reactions. Nuclear dampers have only enough range to be used within the same hex, and are used against missiles which were not destroyed by beam fire.

It is crucial that the damper remain focused on the warhead long enough to disable it. The base difficulty of the nuclear damper attempt is 2. Diff Mods are based on the closing velocity of the missile. The closing velocity of the missile is the number of hexes from the missile's projected endpoint to the target task force's projected endpoint, including either one (but not both) of the endpoint hexes and using the shortest path between the two markers.

The actual Diff Mods applied vary with the tech level of the damper, and are listed below, and repeated on the game reference chart, as "CV" followed by a number. This means that the missile's closing velocity is divided by that number and the result (dropping fractions) is the number of + Diff Mods applied to the task.

Success indicates that the missile's warhead becomes inert, cannot detonate and fire, and is removed from play. Failure means that the missile is still operational and fires.

Nuclear Damper Diff Mods

Damper TL	+Diff Mod
12	CV/2
13	CV/3
14	CV/4
15	CV/5

5. Sandcaster Fire: The ships of the task force allocate their sandcasters against surviving missiles. Because the target ships can project the incoming path of the missiles with some assurance, no task card is turned; all sandcasters directed against missiles automatically hit and subtract 1 point of damage. Sandcasters may only be used for self-defense by a ship, however; a ship may only direct its sandcasters against missiles targeted against itself, not against other ships in the task force.

Firing Missiles

Once all defensive fire by a task force is completed, surviving missiles fire. Missiles resolve their laser fire using a modified version of the normal fire procedures. Missile lasers do not have short, medium, long, and extreme ranges, but rather have an *absolute range* of 0, meaning that they may only fire at targets in the same hex. This is also considered to be the missile's short range, and so the base difficulty level of missile fire is always 1.

Difficulty is modified by target size and target evasion as normal. However, missiles carry no sensors of their own, and rely on sensor updates from the controlling ship. (For an exception to this, see the advanced rules on semi-independent missiles, page 18). For this reason, the absolute range Diff Mods are calculated based on the range from the controlling ship to the missile's target. As is the case with beam weapon fire, the controlling ship's fire control rating may allow some of these Diff Mods to be ignored.

If a hit is scored, turn another card and read the missile damage value to determine the damage level of the hit. Any damage reduction by sandcasters earlier is now subtracted from the damage value. Whether any missiles hit or not, remove the Missile Spread marker from the map at the end of the phase and replace it with a White Out-2 marker.

SENSOR DRONES

Drones are basically larger missiles which carry sensors and do not blow up, but return to their owning ship to be used again.

Two varieties of drones are covered in this game: tech level 12 dual-mode drones and tech level 14 passive mode drones. Their characteristics are listed below.

Drone Characteristics

TL	*Size*	*G*	*Sensors*	*Points*
12	+1	1	A:4, [P:5]	2
14	+1	1(4)	[P:5]	1

TL: Tech level of availability.

Size: The size Diff Mod and damage modifier for the drone.

G: The allowed Gs of acceleration the drone may expend per turn. The parenthetical notation 4 for the TL-14 drone is the total amount of fuel the drone can expend throughout the scenario. (The TL-12 drone has unlimited fuel.)

Points: These are used for victory determination and scenario generation.

Drones are available in scenarios just as are ships. Each drone is controlled by a single ship of equal or higher tech level, which must be recorded before the start of the scenario. If the controlling ship is destroyed or suffers a bridge hit, the sensor drone is removed from play and lost.

This concludes the basic rules. You are now ready to play **Battle Rider.**

SCENARIOS

Battle Rider is played in scenarios, each of which represents an encounter between two hostile groups of vessels. The scenarios presented in the game are described using the following format:

Name: The scenario number and name.

Description: A short paragraph describing the battle recreated by the game scenario.

Red Fleet: This section lists the ships available to the Red player, gives the Fleet Tactics level of the Red commander, and gives the force's general objective.

Blue Fleet: This gives the same information as above, but for the blue fleet.

Advanced Rules: If any advanced rules are required to play the scenario, they are listed here.

Victory: The specific victory conditions to win the scenarios are given. Victory is often based on points worth of ships destroyed. Note that when calculating victory, a ship is always worth its printed point total. If a ship has two different point totals, it is always worth the lower of the two for victory (even if the scenario required purchase using the higher point total).

Variants: Variants to the scenario usually change the mix of ships available or suggest advanced rules to use. If different ships are available, they are usually purchased with points. When variants (or, in the case of the fourth scenario, the basic scenario itself) rely on points to purchase ships, points will usually be used to purchase Fleet Tactics skill as well. The scenario will assume a Fleet Tactics level of 1 and then will list an additional point cost which must be spent to purchase each additional level of Fleet Tactics (up to a maximum level of 7).

Ships themselves and sensor drones are purchased with the remaining points. Drones are color-coded by side and may be used as any type of drone (provided the correct number of points are paid). Ships must be purchased from the pool of available ships.

Pool of Available Ships: The variant notes may specify the pool of ships available to purchase. If not, all ships are divided into two pools as evenly as possible. First, divide every multi-ship class of vessels in two, dividing them between the two pools. Set aside any single-ship classes and the third ships of any three-ship classes.

Next, divide the remaining ships up. Take the extra *Manticore* and place it with the *Maggart*-class LT and treat them as a single ship. Arrange all remaining ships in descending order of points (counting the *Maggart*-class LT as worth simply its own points). Each player now turns a card and the player who turns the card with the highest card ID number takes the highest point ship (*Sylea*). The opponent takes the next highest ship (*Voroshilef*), and so on until all the ships are in one of the two pools. The two *Maggarts* should be placed together in this sequence so that they end up in different pools.

Other Considerations

A number of general considerations affect all scenarios:

Maps: The three maps will always be placed side by side. Unless otherwise specified, both players will begin the scenario by entering the far opposing map edges.

Task Force Entry: Task forces containing ships and drones enter the map on the first turn and do so with a straight-ahead vector of any value desired by the owning player, so long as it is at least a velocity of 1 and no more than the lowest G-rating in the task force. For example, a task force with a ship with a rating of 3G and another with a rating of 6G could have an initial velocity of 1, 2, or 3. The initial vector must be a straight-ahead course pointed down the grain of the hex grid toward the opposing map edge.

Ships may be divided into task forces in any manner desired, so long as the restrictions of the player's Fleet Tactics skill level are observed. At least one task force must, and all task forces may, enter the map on the first turn of the game. Some task forces may delay their entry, but the owning player must record the turn of entry of each delayed task force, along with its initial velocity, which is subject to the same limitation discussed above.

Exiting the Map: Ships which exit the map are permanently removed from play. If they are capable of entering jump space and if they exit along the map edge that their opponents entered along, they may enter jump space and escape. Ships which exit the sides of the map or which are not capable of entering jump space may not escape and are likely to count toward victory by their opponents (but see the individual scenario victory conditions).

A ship is capable of entering jump space if it has a jump drive, has not suffered a permanent computer, bridge, life support, or jump drive damage result, and has not used any of its jump fuel for maneuver (see the Limited Fuel advanced rule, page 19).

The requirement that escape to jump space must be by means of the opponent's map edge is an abstraction and a necessary artifact of a limited playing area. Players with very large playing areas can instead define a "jump line" beyond which any vessel may enter jump space. Using the Advanced Astrographics rule (page 17), select a planet and then define the 100-diameter distance on the playing surface.

Scenario 1: Skirmish

Light fleet elements often precede the "heavies" into an unknown area to trigger enemy ambushes and secure the area for refueling operations. In the many confused frontier actions toward the end of the Final War, light squadrons of the opposing factions often found themselves thrust into sudden and violent contact.

This scenario is a good one to learn with since both sides are evenly matched and have a wide variety of capabilities.

Red Fleet: Scouting elements, Lucan's 7th Vengeance Fleet

Fleet Tactics: 4

Ships: 1 each of the following classes

CL *Starburst*	DE *Chrysanthemum*
ED *Rapier*	CVM *Valor*
DD *Midu Agashaam*	EC *Fiery*

Objective: Secure the star system by eliminating any enemy resistance encountered.

Blue Fleet: Advanced escort elements, Convoy GX-27 (Margaret's Faction)

Fleet Tactics: 4

Ships: 1 each of the following classes

CL *Starburst*	DE *Chrysanthemum*
ED *Rapier*	CVM *Valor*
DD *Midu Agashaam*	EC *Fiery*

Objective: Secure the star system by eliminating any enemy resistance encountered.

General Information:

Advanced Rules Needed: None

Victory: The last player to have an operational ship on the map is the winner. If both players lose their last operational ship in the same turn, the game is a draw.

Variant: Players secretly purchase their vessels from the available pool of ships. No non-jump-capable ships may be purchased. Both sides have 208 points to spend on vessels and Fleet Tactics. Fleet Tactics level is 1 unless a higher skill is purchased; each increase of 1 (to a maximum of 7) costs 10 points.

Scenario 2: Task Force Dagger

The Reformation Coalition undertook to subdue a extraordinarily large volume of space with very slim resources. Their only hope for success was to use their resources sparingly and always to good effect.

The warlords of the planet Montezuma had been carefully assembling a small fleet of interplanetary combatants designed to protect their world from Star Viking (Reformation Coalition) operations. When word was received on Aubaine that a derelict warship had been recovered from the asteroid belts of Montezuma's star and added to its small fleet, the Assembly decided that it was time to act. A small task force was assembled from whatever vessels could be spared from other duties and sent to Montezuma.

Red Fleet: Task Force Dagger, Reformation Coalition Navy (RCN)

Fleet Tactics: 4

Ships: 1 each of the following classes

LM *Aurora*	SM *Victrix*
LC *Aurora*	2 TL-12 Drones
CR *Ashtabula*	

Objective: Cripple the Montezuman Navy at a minimum cost in friendly vessels.

Blue Fleet: Montezuman High Guard

Fleet Tactics: 1

Ships: 1 each of the following classes

DE *Chrysanthemum*	CP *Patrol Cruiser*
SDB *Shukugan*	EC *Gazelle*
MA *Mary Ellen Carter*	

Objective: Defend the home system and punish any attempt at invasion.

Special Rules: The Montezuman *Chrysanthemum*-class destroyer escort has no missiles loaded and only one of its two spinal mount particle accelerators is operational. Ignore the jump ratings for all Montezuman ships (none are jump-capable) and treat them as having no fire control equipment. In addition, whenever a Montezuman ship suffers a Life Support hit, it may conduct no actions in its next operation round (may not fire, maneuver, or detect) and may not control any missiles in the next Missile Movement and Missile Attack Phases. (The crew is completely occupied trying to find and put on vacuum suits.) Finally, as Montezuman

damage control parties are poorly trained and equipped, return any No Effect damage tokens and keep drawing replacements until a token other than No Effect is drawn.

General Information:

Advanced/Optional Rules Needed: Boarding Actions.

Victory: The scenario ends when one side or the other has no ships remaining on the map capable of attacking with either beam weapons or missiles. To win, the Coalition player must destroy Montezuman ships whose point total is at least 15 *and* is at least twice the point total of Coalition ships lost. A Montezuman ship is destroyed if it suffers a Ship Destroyed result in combat, exits the map, or is successfully boarded and captured by a Coalition ship (see optional Boarding Actions rule, page 25). A Coalition ship is lost if it suffers a Ship Destroyed result or exits the map unable to enter jump space. In addition, any Coalition ship left on the map at the end of the scenario is considered lost unless either it is capable of entering jump space or there are no Montezuman ships left capable of attacking.

Variant 1: The Coalition player places the four ships in a cup, draws one at random, and sets it aside. This ship does not participate in the action. (This variant tips balance toward the Montezuman player.)

Variant 2: Use the advanced rule for Crew Quality (page 18). All Coalition crews are crack and all Montezuman crews are green. (This variant tips balance toward the Coalition player.) Note that variant 1 and 2 can be used together.

Variant 3: Players secretly purchase their vessels from the available pool of ships. The Reformation Coalition pool of available ships includes all those part of Task Force Dagger in the original scenario as well as both *Maggart*-class ships, all three *Manticores*, the *Lancer*, and the *Fusilier*. All other ships worth less than 15 points are in the Montezuman pool.

The Coalition player has 63 points to spend on ships and Fleet Tactics. Fleet Tactics level is 1 unless a higher skill is purchased; each increase of 1 (to a maximum of 7) costs 3 points. If *Manticores* are purchased by the Coalition player, sufficient *Maggarts* must be purchased to transport them.

The Montezuman player automatically has the *Chrysanthemum*-class destroyer escort in the condition described in the basic scenario and has 35 additional points to spend on ships and Fleet Tactics. Fleet Tactics level is 1 unless a higher skill is purchased; each increase of 1 (to a maximum of 7) costs 3 points.

Scenario 3: First Clash

The Reformation Coalition was not alone in its efforts to recover and expand in the vacuum left by the collapse of the Third Imperium. Immediately to coreward, no more than a dozen or so parsecs from the Coalition frontier, lay the fledgling Empire of Solee. Although much smaller than the Coalition in population and worlds controlled, it had the advantage of a large cache of relatively intact Imperial Navy vessels waiting to be repaired and recrewed. Lacking Hiver technical assistance, the process was painstaking and the crews learned by trial and error. But eventually Solee would be able to assemble a nearly irresistible naval presence if left to grow undisturbed. Frontier friction quickly turned to open warfare, and the Coalition's first generation of purpose-built warships received their baptism of fire.

Red Fleet: Task Group 17, Reformation Coalition Navy (RCN)

Fleet Tactics: 4

Ships: 1 each of the following classes

LT *Maggart*	DD *Lancer*
LC *Maggart*	DD *Fusilier*

Plus a total of 3 BRL *Manticores* carried on the *Maggarts* and 2 TL-12 Drones

Objective: Seek out and engage the Soleean Empire's advanced elements and inflict serious damage on them.

Blue Fleet: Cruiser Scouting Detachment 1, Soleean Grand Imperial Fleet

Fleet Tactics: 3

Ships: 1 each of the following classes

CL *Starburst*	DE *Chrysanthemum*
ED *Rapier*	CP Patrol Cruiser
DD *Midu Agashaam*	Plus 2 CVM *Valors*

Objective: Avoid decisive losses from enemy craft while gaining combat experience for the crews.

General Information:

Advanced Rules Needed: Crew Quality. All Coalition crews are crack; all Soleean crews are green.

Victory: The scenario ends when one side or the other has no ships remaining on the map capable of attacking with either beam weapons or missiles.

The Coalition player must destroy Soleean ships whose point total is at least 50 *and* is at least 10 points greater than the point total of all Coalition ships destroyed. A ship is destroyed if it suffers a Ship Destroyed result or exits the map unable to enter jump space. In addition, any ship left on the map at the end of the scenario is considered lost unless either it is capable of entering jump space or there are no enemy ships left capable of attacking.

The Soleean player must avoid the Coalition victory conditions *and* escape with ships whose combined point value is equal to or greater than 25.

Failing a win by either side, the scenario is a draw.

Variant: Players secretly purchase their vessels from the available pool of ships. The Soleean Empire pool of available ships includes all tech level 15 ships except for the CR *Ashtabula*. All remaining ships form the Coalition pool of available ships. Both sides have a total of 167 points to spend on ships and Fleet Tactics. Fleet Tactics level is 1 unless a higher skill is purchased; each increase of 1 (to a maximum of 7) costs 8 points.

If this variant is used, the advanced game scenario purchasing system (including Crew Quality) should be used as well. The Soleean player may only purchase ships with green crews. The Coalition player may purchase ships with crews of any desired quality level.

If *Manticores* are purchased by the Coalition player, sufficient *Maggarts* must be purchased to transport them.

Scenario 4: Battle Royal

When major fleet elements encountered each other with blood on their minds, the resulting battle was usually quick and extraordinarily violent. The following scenario is typical of of a smaller action fought between battle fleets in the closing months of the Final War.

Red and Blue Fleets:

Ships: Both sides purchase their fleets using the point system. Available ships are divided into two pools as described in the scenario main rules above. Both sides have 1200 points with which to purchase ships and Fleet Tactics. Neither side may purchase non-jump-capable ships unless tenders capable of carrying them are also purchased.

Fleet Tactics: Fleet Tactics level is 1 unless a higher skill is purchased; each increase of 1 (to a maximum of 7) costs 60 points.

Objective: Total annihilation of the enemy.

General Information:

Advanced Rules Needed: None, but Crew Quality is recommended. If this advanced rule is used, the advanced rules for fleet purchase should also be used, including costs for crack and green crews.

Victory: The last player to have an operational ship on the map is the winner. If both players lose their last operational ship in the same turn, the game is a draw.

ADVANCED RULES

ADVANCED ASTROGRAPHICS

Gravity

Gravity has very little effect in **Battle Rider.** This is because Gs are measured in whole numbers, and no worlds which fit onto Battle Rider counters extend their 1G field out of their own hex. Larger bodies such as stars and large gas giants would certainly do so, and sample figures are given below. **Battle Rider** does not contain templates for such large bodies, but players should feel free to make their own.

Effects: Any craft that is within the 1G threshold of an astronomical body has 1 G-turn added to its vector each turn in a direction directly at the center of the body. A craft within the 2G threshold has 2 G-turns added to its vector each turn, and so on. These G-turns must be counteracted by the craft's own drives, or else its vector will be bent toward the gravity source.

G thresholds are calculated by using the formula

$$\frac{\sqrt{GM \div g}}{3 \times 10^7} = \text{range in hexes}$$

$G = 6.67 \times 10^{-11}$
M = body's mass in kg
g = 9.8 × G threshold desired

Remember to subtract the body's radius to get the range above its surface to the threshold.

Stars

Stars are far too large to be portrayed in **Battle Rider.** In the **Battle Rider** scale, our sun would have a diameter of 46.5 hexes. Its 1G threshold would extend out another 99.5 hexes from its surface (2G threshold at 63.5 hexes, 3Gs at 47.6, 4Gs at 38 hexes, etc.), and there would be tremendous + Diff Mods against sensor tasks within this area and beyond.

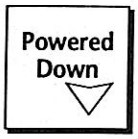
Planets

At the scale and distances from the system's primary star represented in **Battle Rider,** the orbital paths of planets show no curvature and are treated as perfectly straight lines. Planets may be given a heading and velocity in the scenario instructions, and these will not change during play for any reason.

The planets represented by counters in **Battle Rider** are Terra-size worlds, as even small gas giants take up multiple hexes.

Take-Off and Landing: Any ship that wishes to land on a planet must first match vectors with it in the same hex. This means that craft must spend one game turn in which their movement from hex to hex is identical to that of the planet. On the first game turn following, the craft can announce that it is landing, which takes the entire turn. Craft which are landed on a world have a +2 Diff Mod applied to sensor tasks against them if the world has an atmosphere of Very Thin or less, +3 if the atmosphere is Thin or greater, and +4 if the atmosphere is Exotic, Corrosive, or Insidious. In addition, any craft landed on a planet with a Hydrographic rating of 1 or more may declare that it is underwater, in which case an additional +1 Diff Mod is applied.

Taking off from a Terra-sized planet also takes a full turn. At the end of this turn, the craft has a vector identical to that of the planet.



Sample Planets: To assist players in designing their own scenarios, the following planetary statistics from our own Solar System are presented in **Battle Rider** terms as examples. 1G threshold is given in hexes beyond the planet's surface. Velocity is orbital velocity, and has nothing to do with the rate that our entire Solar System is scorching around the core of the Milky Way (12 hexes per turn, in BR scale, is our "local standard of rest").

Planet	*Diameter in hexes*	*1G Threshold*	*Velocity in hexes per turn*
Mercury	0.16	Below surface	2.87
Venus	0.40	Below surface	2.1
Earth	0.43	Surface	1.787
Mars	0.23	Below surface	1.45
Jupiter	4.76	1.4 hexes	0.78
Saturn	4.00	0.07 hexes	0.58
Uranus	1.86	Below surface	0.41
Neptune	1.62	0.07 hexes	0.33

There are two equally valid ways to handle planetary (and asteroid belt) motion in **Battle Rider.** One is to have the maps represent a motionless chunk of space and have the astronomical bodies move across them at their appointed rates. Another is to pick the planet or asteroid belt as the frame of reference so that they remain motionless and drag the visual window represented by the map along with them. Both are perfectly correct, but the latter is usually much easier.

POWERED DOWN

A ship which is in cold mode, with its power plant powered down to minimal levels (assume 1% of maximum power plant output), presents a very difficult target to passive sensors. Ships which are powered down have a +2 Diff Mod applied against attempts to detect them using passive sensors.

Ships which are powered down may not maneuver, jam hostile sensors, fire energy weapons, nor operate any active sensors or screens (meson, damper, or black globe). The ship may fire missiles and sandcasters and operate passive sensors at +1 Diff Mod.

However, this tactic can backfire if the ship has to start up quickly. To bring the power plant up to full power normally requires a full 30 minutes, leaving the vessel vulnerable for an entire turn. To show this, a Powering Up marker is placed on the ship at the start of its operation round, and the marker is removed at the start of its next operation round. While powering up, the ship suffers all of the limitations of being powered down, but does not enjoy the +1 Diff Mod against passive detection attempts.

Rather than waiting, the player may attempt a crash start-up. A crash start-up is a task with a difficulty level of 4. Success indicates that the power plant is immediately on-line, while failure indicates that the ship will have to wait the full turn to power up.

BLACK GLOBES

Black globes are highly sophisticated and exotic defensive screens. Even at the height of the Third Imperium's technology, only the most basic black globe screens could be reproduced. The best black globes in use were recovered relics from an ancient civilization that pre-dated humanity's starfaring days. Thus black globes are only rarely encountered.

Although these weapons are very advanced from an engineering and scientific standpoint, their use is very simple. Black globe generators create a spherical field around themselves which absorbs all energy that crosses it. This energy is shunted into capacitors within the hull of the protected vessel where it is stored. This screen can be also set to flicker at a set percentage rate in multiples of 10%. (The

single ship with a black globe in **Battle Rider,** *Kinunir,* has only one flicker rate for its black globe: 10%.)

The decision to turn the black globe off, turn it on to full, or set it to flicker is made at the start of the vessel's peration round, and is marked with one of the counters provided.

Combat: When set all the way up, the black globe absorbs the energy of all weapons which successfully rolled to hit the target. For example, each hit from a 7 damage value meson gun would place 7 DP into the capacitors of the protected ship.

When the weapon is set to flicker, all weapons which successfully made "hits" then determine if they were absorbed by the globe or passed through to hit the target normally. For each hit, turn a card. If the last digit of the card's identity number is higher than the flicker rate divided by 10 (i.e., turn a 2+ to get through 10% flicker), the hit penetrates the black globe and does full damage. Hits which do not penetrate are completely absorbed.

Outgoing fire is not affected, as it is synchronized to match the flicker.

Capacitors installed aboard the ship will have a listed capacity in damage points. If this limit is ever exceeded, the capacitors spontaneously discharge. Turn two Missile Damage cards, add the results, and inflict that number of damage results on the vessel, plus the vessel automatically suffers both a power plant and jump drive critical hit.

When set to flicker, the only fire which can overpower the capacitors is fire whose damage value exceeds the capacitor's storage level. That is, a ship with a flickering black globe and a size-9 capacitor can take an unlimited number of hits with a damage value of 9 or less during a turn, but a single hit with a damage value of 10 or more will overload the capacitors.

While the screen is completely up, the capacitors can be overloaded in the way described above, or they can be overloaded by cumulative energy. In each operation round in which the globe is completely up and in which the ship is hit by at least one weapon with a damage value of 2 or more, the capacitor value of the shield is reduced by 1. Note that this reduction makes it easier for weapons to overpower the screen in later operation rounds. This reduction is made regardless of how many or how few weapons hit. The reduction is in effect until the vessel turns off its black globe completely. Incoming sensor and communicator energy absorbed by the black globe is considered to be negligible.

Kinunir's capacity is 10 damage points.

Maneuver: When its globe is all the way up, a vessel cannot maneuver to change its vector or attempt to evade. When the black globes available in this game are set to flicker, they allow normal maneuver.

Sensors: A vessel with its black globe fully up may not detect targets or make fire control lock attempts.

Detection and fire control lock attempts against a full-up black globe have a +5 Diff Mod vs. active sensors and a +3 Diff Mod vs. passive sensors for the black globe, and the only additional Diff Mods that apply are those for target size, fire control lock, terrain, area jamming, and white out.

Detection and fire control lock attempts against a flickering black globe (as well detection and fire control lock attempts by ships using flickering black globe) use all of the standard sensor lock Diff Mods, with the addition of the black globe flicker Diff Mods. For both active and passive sensors, divide the flicker rate by 30 and round to the nearest whole number to get + Diff Mods. Thus, 10% is 0 Diff Mod, 20-40% is +1 Diff Mod, 50-70% is +2 Diff Mod, and 80-90% is +3 Diff Mod.

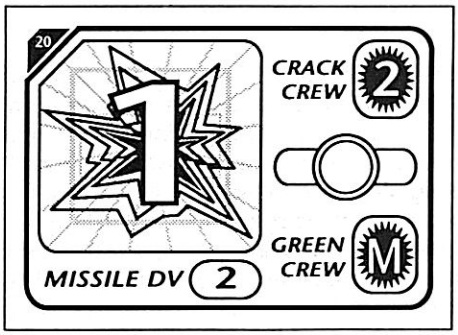
As with normal detection tasks, the target player is responsible for calculating certain of the Diff Mods for the task, but the emissions signatures of a flickering black globe are distinctive enough that anyone who attempts to detect a flickering black globe should be given that information whether the attempt is successful or not.

SEMI-INDEPENDENT MISSILES

Missiles which carry their own sensors but which are still controlled by their firing gunner (as discussed in the basic rules above) are referred to as semi-independent missiles (SIMs). SIMs may attempt to detect targets just like spacecraft, but only controlled SIMs may do so and each SIM may only make one detection attempt per turn. This detection attempt is either before or after the missile moves, at the owning player's option.

When SIMs fire, they may attempt a fire control lock with their own sensor instead of the firing ship's. If successful, the absolute range Diff Mod is based only on the range from the SIM to the target. If unsuccessful, the missile may still fire, but a fire control lock from the controlling ship is necessary and absolute range Diff Mods are calculated from the controller to the target just like normal missiles.

There are two types of semi-independent missiles: tech level 12 and tech level 14. Characteristics of these, plus the basic controlled missiles, are listed below and on the Player Aid Card for ease of use during play. The table below lists their maneuver characteristics in total G-turns, the size modifier of the missile, and the sensor rating of the missile (if any).



Missile Characteristics Chart

Type	*Gs*	*Size*	*Sensor*
Controlled Missile	G:12	+2	—
TL-12 Semi-Ind	G:9	+2	P:1
TL-14 Semi-Ind	G:7	+2	P:3

CREW QUALITY

All task attempts in the basic game assume an average crew quality. Exceptional crews are capable of much more, while untrained or inexperienced crews tend to fail more often. In the game this difference is expressed by terming a crew "crack" or "green."

Average crews (the majority) use the task cards normally. Crack and green crews do as well, except when a different value appears in the crack or green crew fields. In this case, the value shown there is used instead.

For example, if a player attempts a task with a difficulty level of 2 and draws card with a value of 1, the task fails. If, however, the ship attempting the task had a crack crew *and* the card drawn had a value of 2 in the crack crew data field (see example above), the task would succeed.

By the same token, a task with a difficulty of 1 would normally succeed if the illustrated card were drawn, but would fail if it were drawn by a green crew.

A card with a bull's-eye result in the crack crew data field is treated like a bull's-eye in all respects when drawn by a crack crew, including causing double damage.

MULTIPLE FIRING BATTERIES

Very large ships (those with a size value of –2, –3, –4, or –5) mount more weapons than can be brought to bear in a single direction. The ratings provided on the ship counter for all dampers, sandcasters, and beam weapons (except spinal mounts), are actually the values for a single "battery" of weapons. Each ship has batteries equal to the absolute value of of its size value (except that vessels with a size code of +2 and 0 both have only a single battery.)

A battery is the maximum number of weapons which may fire through a single hexside, or fire at missiles entering the ship's hex across a single hexside. A ship may split the fire of battery between several hexsides, but may not fire more than a battery through a hexside in a phase.

Each ship may fire each battery once per game turn. Some or all batteries may fire during the Operations Phase and then the remainder may fire during the Missile Attack Phase. (This is abstracted in the basic game by allowing ships with one battery to fire in either phase and allowing ships with two or more batteries to fire once in each phase.) Players must keep track of how many batteries fired in the Operations Phase so that they know how many remain to fire in the Missile Attack Phase.

All nuclear dampers from all batteries are assumed to be available for fire in the Missile Attack Phase.

Note that spinal mounts are not part of any battery and are not affected by this rule in any way.

SOCKET EXTENDERS

Some vessels mount their weapons on socket extenders to allow more of them to bear on a target at one time. These vessels have the notation "E" following their size codes. Socket extenders have the following effects:

Batteries: Ships with socket extenders may fire two batteries through each hexside instead of only one.

Detection: Ships with socket extenders subtract 1 from their size rating (–2 becomes –3, for example) when the opposing player makes active detection attempts against them.

LIMITED FUEL

Some ships, marked with an asterisk following their G-rating, have only limited maneuver fuel. At the start of the scenario, draw three cards and add the missile damage values from the cards together. The result is the number of G-turns of maneuver fuel carried in the ship. Repeat this for each ship with limited fuel in the scenario.

Each time that a ship expends a G for thrust or evasion, the owning player marks off a G-turn of maneuver fuel. If, for example, a ship expended 2Gs for maneuver and 3Gs for evasion in an Operations Phase, the owning player would mark off a total of 5 G-turns of maneuver fuel.

Once a ship's maneuver fuel is expended, it may not expend any more maneuver or evasion Gs without consuming the reserve of fuel necessary to make an interstellar jump. In some scenarios this will not matter, but if the ship needs the capability to jump out of system to escape this can be crucial.

CROSSING MOVEMENT

Crossing movement occurs when a task force moves between a ship and its intended target, whether the target is the object of a detection attempt or actual fire combat. A detection or fire attempt is affected by crossing movement when the line from the detecting/firing ship to the target passes through the imaginary line connecting a Task Force counter (friendly or enemy) with either its Projected Endpoint marker or its Previous Position marker, whichever is currently on the map.

Note that movement by the firing/detecting task force and the target are never considered crossing movement.

All tasks affected by crossing movement are subject to a +1 Diff Mod. Tasks which are subject to crossing movement due to more than one task force suffer a cumulative +1 Diff Mod per crossing task force.

ADVANCED TECH LEVEL EFFECTS

Here are two additional tech level effects which add color to the game but were not appropriate to the basic game rules.

Sandcasters: Tech level 15 sandcasters which hit negate 2 points of laser or particle accelerator damage instead of 1. Outstanding Success negates 4 points of damage.

Going Active: In the basic game there is a –1 Diff Mod on attempts to use passive sensors to detect ships which are using their active sensors. In the advanced game, this Diff Mod is applied only if the detecting ship is from a tech level equal to or higher than the active ship.

ADVANCED SCENARIO GENERATION

The advanced scenario generation system is designed to provide a nearly limitless selection of game situations for players, as well as inserting a strong dose of uncertainty in each scenario. The advanced scenarios assume two "pocket empires," comparatively small clusters of worlds in close proximity to each other but surrounded by the "Wilds," the vast, devastated and technologically regressed area of settled space that constitutes the bulk of the ruins of the old Third Imperium.

The two pocket empires have come into contact with each other and are engaged in low-level border fighting, struggling for naval supremacy while also engaged in diplomatic maneuvering with each other and with the few remaining interstellar mercantile interests.

The slowness of communication, the lack of reliable intelligence about the opponent, and the frequent misunderstandings as to motives of enemies and neutrals, makes the situation fraught with uncertainty, especially for the local naval commanders who have to wage an increasingly violent war almost in the dark.

Sides: The two sides, red and blue, divide the ships in the game into two pools of available ships, just as described in the basic game's scenario section, with one exception: All four extra *Gallant*-class battle riders and both *Shukugan*-class system defense boats are automatically assigned to the Blue pool of available ships.

Although the initiative shifts between the two pocket empires, with first one and then the other engaged in offensive acts, for scenario purposes the Red side will always represent the intruder while the Blue side will always represent the native, or defending, player.

Astrographic Bodies: Place the planet and four asteroids on the map at the beginning of each scenario. Place the planet in hex 1010 of the map closest to the blue entry edge. In all scenarios, the Blue player will start with ships on or near the planet, and it will often be the focus of activity in the scenario. The Blue player then places two asteroids in any hex of the central map. Finally, the Red player places the remaining two asteroids in any two hexes of the map containing the planet, but at least four hexes away from it.

Set-Up: The Red player always enters the map with at least one task force on turn 1, and may enter all task forces on that turn or later turns. (The Red player follows the basic game's scenario instructions for entry.) The Blue player may place her task forces landed on the planet, in orbit, stationary in any asteroid hex, or anywhere within five hexes of the planet with an initial vector of one hex per turn in any direction. Some Blue forces may be held off-map for entry later if the mission instructions so specify.

Missions: Each player has 10 numbered Mission markers. To prepare for play, each player draws one Mission marker from the mix and reads the mission statement given below. For ease of scenario preparation, we encourage players to photocopy these mission descriptions so each player has a copy (and hereby give specific permission to do so for this purpose).

Each mission consists of a general description of the player's objectives, a point total to spend on ships and other assets, and a precise statement of victory conditions for the scenario.

The base point values below are for medium-sized scenarios. For larger scenarios, double the points. (For really insane scenarios, triple them.)

Spending Points: Points may be spent for ships and to purchase higher levels of Fleet Tactics skill. The assumed Fleet Tactics level of a side is 1, and each additional level of tactics costs 5% (round fractions to the nearest whole number) of the total points available, up to a maximum Fleet Tactics level of 7.

Ships may be purchased by spending the points printed on the vessel. The Red player may not purchase battle riders without also purchasing tenders sufficient to carry them. The Blue player may purchase battle riders without tenders, but if so must pay the second (higher) price for them. (If purchased with tenders the lower price is paid.)

Ships may be purchased with SIMs instead of regular missiles. A ship carrying SIMs has its price multiplied by 1.05 if half of its missiles are SIMs and by 1.1 if all of its missiles are SIMs. A ship may not carry SIMs from a higher tech level than the ship's own tech level.

Drones may also be purchased for the points listed in the basic rules. Each drone must be assigned to a specific ship, and may not be assigned to a ship of a lower tech level than the drone itself.

Crew Skill: The base purchase price of the ship assumes an average crew. Individual ships may be purchased with crack or green crews at different prices. If purchased with a crack crew, multiply the ship's point value by 1.2. If purchased with a green crew, multiply the ship's point value by 0.8.

Victory and the Turn Record: If only one side fulfills its victory conditions, that side wins and the opposing side loses. If neither side fulfills its victory conditions, both sides lose (the scenario is a draw).

Many scenario victory conditions are dependent on the point level of the opponent, which is not known until after the scenario is over. As a result, it is possible for one side to win and not know it until much later, and it is sometimes possible for both sides to win. As a result, a complete turn record should be kept. At the end of each turn make a check mark after the turn number. If any ships escaped or were destroyed during the turn, record the name and side by the turn number. Likewise, if a successful bombardment was carried out or if a covert team was recovered, record that here as well. If both sides fulfill their victory conditions, the winner is the side which did so first, which can be established by consulting the written turn record.

Intruder (Red) Missions

1. Command of the Spaceways

Mission: Your fleet is to crush all enemy naval opposition in the system as a prelude to further advances on the enemy home system. The planet itself is unimportant and can be bypassed, but all enemy ships must be destroyed. If any enemy vessels escape, you lose.

Points: 500

2. Invade and Secure

Mission: Your fleet is to bombard the planet surface and then land a substantial force of ground troops to seize the key ground installations necessary to control the planet. A total of four turns of bombardment must precede the landing of assault troops, each turn consisting of 10 missiles fired from orbit at the planet surface.

Following bombardment, ground troops may be landed. Only ships with a size code of –3 or –4 may land ground troops. Each size –3 ship in orbit lands one ground troop per turn. Each size –4 ship lands three ground troops per turn. In the Missile Attack Phase of each turn, local ground troops fight back by turning one card and subtracting the missile damage shown from the total number of ground troops landed so far. The invasion succeeds when the cumulative total of landed ground troops (minus casualties) reaches 20. Invasion success is determined during the Initiative Phase of each turn.

Points: 450

3. Probing Attack

Mission: Your fleet is to test the enemy defenses and, if a weak spot is found, press hard. If you have more points than the enemy, you win by controlling the map at the end of the scenario (all enemy ships destroyed, disabled, or escaped). If you have twice as many points as the enemy, you win only by destroying or disabling all ships (and escapes prevent you from winning). If you have three quarters or less as many points as the enemy, you win by disabling or destroying more enemy ships than you lose.

Points: 300

4. Surface Raid

Mission: Intelligence operatives have uncovered evidence of an important technological breakthrough by enemy researchers based on the target world. Your mission is to land a commando team on the world and then extract them 10 turns later (after which they will have secured and neutralized the enemy research facility and made a complete copy of all databases).

The commando force will be landed under cover of a surface bombardment. A total of two turns of bombardment, each turn consisting of 10 missiles fired from orbit at the planet surface, are necessary to cover the landing. Once the second turn of bombardment is complete, the commandos are landed and begin their mission. (You need not, and should not, tell the opposing player that the commando mission is taking place.) Starting 10 turns after the commandos land, they may be extracted. Any ship in orbit over the planet can extract them. Successful extraction is a task with a difficulty level of 1, with crew quality of the extracting ship counting toward success or failure. Each turn after the tenth turn, apply one additional +1 Diff Mod. (+1 Diff Mod on turn 11, +2 Diff Mod on turn 12, etc.) Extraction may be attempted after turn 14, but only a Bull's-eye result will result in successful extraction.

Extraction may only be attempted once. If it fails, the commando team has been captured and the mission is a failure. If it succeeds, the ship containing the commando team must escape from the map. If it is destroyed or disabled, the mission fails.

If the enemy has more points than you do, you win if you successfully complete the bombardment and land the commando team. Extraction and escape are not necessary.

Points: 300

5. Bombardment

Mission: Enemy raids against friendly commercial shipping have been staged out of the target world, and maintenance facilities on the planet surface are key to continuing the raids. Your mission is to destroy those facilities without suffering crippling losses. A total of two turns of bombardment, each turn consisting of 10 missiles fired from orbit at the planet surface, are necessary to destroy the maintenance facilities.

If your point total is equal to or greater than the enemy total, you must carry out the bombardment and suffer no more losses than 1.5 times those suffered by the enemy. If your point total is less than the enemy total, you win simply by successfully carrying out the bombardment, regardless of losses.

Points: 250

6. Hit And Run

Mission: While our forces are still weak in this area, it is necessary to convince the enemy that a major effort is planned here so that enemy naval reserves will be drawn away by our main effort. If you have equal or fewer points than the enemy, your squadron must destroy at least one enemy ship and then escape. If you have more points than the enemy, you must destroy more points of enemy ships than you lose and then escape.

Special Note: In this scenario, you can escape off of either your map entry edge or the hostile map entry edge.

Points: 200

7. Propaganda Raid

Mission: Recent operations by hostile naval elements have been extremely successful, and the enemy has amassed a preponderance of naval forces in this area. Both for diplomatic purposes and to strike a blow at enemy morale, it is necessary to prove that even the largest enemy fleet units are not safe.

Your squadron is directed to engage the enemy and, at whatever cost necessary, destroy or seriously damage a large enemy combatant vessel (size code –3 or –4). If your point total is less than the enemy's, you win if you inflict one hit (other than a no effect) on a size –3 or –4 ship. If your point total is equal to or greater than the enemy's, you win if you destroy a size –3 or –4 ship or, if none are in the scenario, over half of the point total of the enemy fleet.

Special Note: In this scenario, you can escape off of either your map entry edge or the hostile map entry edge.

Points: 150

8. Transit

Mission: Your squadron is needed to reinforce another squadron at a nearby star. In order to make the jump, your ships must take on additional fuel. One of the asteroid clusters on the map (you select which one and record its map and hex number before play begins) is mostly hydrogen gas chunks. To refuel, each of your ships must spend one turn stationary in the same hex as the asteroid. Once refueled, your ships may exit and escape into jump space.

If your points are equal to or greater than the enemy's points, you win if over three quarters of your ships (by point value) escape. If your point total is less than the enemy's, you win if half of your ships escape. If your point total is less than half of your enemy's, you win if any of your ships escape.

Special Note: In this scenario, once refueled you can escape off of either your map entry edge or the hostile map entry edge.

Points: 150

9. Deep Black

Mission: A clandestine intelligence-gathering station has been at work in the enemy system for several months. Your mission is to extract the personnel and collected intelligence data from the secret base. The secret base is located on one of the asteroids (you select which one and record its map and hex number before play begins). To extract the team, one of your ships must spend one turn stationary in the same hex as the asteroid. Once the team is extracted, your ships may exit and escape into jump space. If the team is extracted and the ship carrying the team, or any ship which was part of the same task force as that ship at any time after the extraction (allowing the database to be transferred by tight beam communications), escapes, you win.

Special Note: In this scenario, you can escape off of either your map entry edge or the hostile map entry edge.

Points: 100

10. Snoop 'n' Scoot

Mission: Naval Intelligence suspects an enemy build-up in this area, but needs to have precise information on the size and scope. Your squadron is to detect enemy ships operating in the neighborhood of the star and report back to fleet headquarters. You win if you detect 300 or more points worth of enemy ships or every enemy ship (whichever is less), and escape with at least one ship.

Special Note: In this scenario you can escape off of either your map entry edge or the hostile map entry edge.

Points: 50

Blue (Native) Missions

1. Ambush

Mission: Naval Intelligence has determined that the enemy is planning an operation against this system, although the nature of that operation is unclear. This information gives us an excellent opportunity to inflict a major defeat on our enemy and alter the naval balance of power in this area.

A covering force is in place around the main world while a much larger fleet is hidden in a denser asteroid belt (off-map). The ambush force may enter on your map entry edge anytime on or after turn 6. Your mission is to thwart any enemy plans directed at the system and crush the forces committed here. To win you must prevent the enemy from gaining his victory conditions and you must destroy every enemy ship in the scenario. (If any escape, you lose.)

Points: 500 (up to 150 on the map, up to 350 enter turn 6 or later)

2. Vampire!

Mission: When Virus, the self-aware combatant computer program, swept through the Third Imperium it brought on the Collapse and ended the Final War. Mostly as self-destructive as it was murderous, there remain few examples of functioning Virus in human space, but most survivors, inhabiting the computer brains and control systems of starships, have gathered together for self-defense. These groups are called vampire fleets by humans, and your ships make up such a fleet.

Your objectives are to destroy human ships and, if possible, survive (to destroy more). To win you must destroy more human ships (in terms of point value) than you lose. Human ships which you disable and successfully board (see optional Boarding Action rule) count as double points toward victory (as its computer brain has been infected and taken over by you).

Special Note: Any computer hit on one of your ships destroys it.

Points: 400

3. Naval Supremacy

Mission: Naval command has assembled a powerful squadron of warships under your command to enable you to frustrate any enemy plans in this star system. To win you must prevent the enemy from achieving her victory conditions.

Points: 350

4. Active Defense

Mission: Naval command has assembled a powerful squadron of warships under your command to enable you to maintain control of this star system. If you have equal or greater points than your opponent, you must thwart the enemy victory conditions and have the only operational ships left on the map at the end of the scenario. If you have fewer points than the enemy, you must destroy more enemy ships (in terms of points) than you lose.

Points: 300

5. Fleet In Being

Mission: Your fleet is the only group of major naval combatants we have in this stellar region. It is vital, therefore, that it be preserved intact, even at the price of surrendering this planetary system.

If your point total is equal to or less than that of your enemy, you win if your losses at the end of the scenario are equal to or less than

one-third of the point total of the enemy fleet. If your point total is greater than your enemy's, you must meet the same criteria and in addition must prevent her from achieving her victory conditions.

Points: 300

6. Convoy Run

Mission: While your main body occupies the attention of the enemy, a detached squadron is to escort a critical merchant convoy out of the system. When purchasing vessels, you may purchase as many as desired as "merchant ships." Merchant ships cost half their printed point value, have no offensive weapons except their laser turrets, have no defensive shields except their sandcasters, have no active sensors, jammers, or masking, have no fire control equipment, and have an armor value of 0. They are otherwise identical to the ship purchased. Note which ships are merchants before the scenario begins. All merchant ships must have jump drives.

The merchants and their escorts (up to a total of 100 points worth of ships) enter on or after turn 6, while all other ships begin the scenario on the map. If you have points equal to or greater than your opponent, you win if all of the merchant ships escape. If you have points less than the total enemy points, you win if half or more of your merchants (by point value) escape. If you have points equal to 150 or more less than your opponent, you win if one merchant ship escapes.

Points: 250 (up to 150 on the map, up to 100, including all merchants, enter turn 6 or later)

7. Economy of Force

Mission: The naval command has limited fleet resources in this area and expects you to make optimal use of those assigned to you. To win you must destroy more enemy ships (by point value) than you lose. If you have total points equal to or greater than the enemy, you must also prevent the enemy from achieving her victory conditions.

Points: 250

8. Delaying Action

Mission: No enemy naval operations were expected against this system and your forces are inadequate for defense. Your mission is to conduct a skillful delaying action. If your point total is less than the enemy, you win if you can delay the enemy victory conditions for 20 turns and then escape with at least one ship. If your point total is equal to or greater than the enemy, you win by frustrating his victory conditions.

Points: 200

9. Desperate Defense

Mission: No enemy naval operations were expected against this system and your forces are inadequate for defense. It is vital for the honor of the fleet, however, that you inflict some telling damage on the enemy before being overwhelmed.

You must engage the enemy and, at whatever cost is necessary, destroy or seriously damage a large enemy combatant vessel (size code –3 or –4). If your point total is less than the enemy's, you win if you inflict one hit (other than a no effect) on a size –3 or –4 ship. If your point total is equal to or greater than the enemy's, you win if you destroy a size –3 or size –4 ship or, if none are in the scenario, over three-quarters of the point total of the enemy fleet.

Points: 150

10. Escape

Mission: No enemy naval operations were expected against this system and so your forces are inadequate for defense. It is vital that at least one ship escape to carry news to the high command of this enemy offensive.

You win if one of your ships escapes into jump space, unless the enemy has points equal to or less than yours, in which case you win by thwarting her victory conditions.

Points: 100

OPTIONAL RULES

MULTIPLE PLAYERS

If multiple players are present on each side, the available ships are divided among them in any manner acceptable to all of them, and the player with ships having the greatest total point value is designated the fleet commander. The fleet commander has the Fleet Tactics skill level specified for that side in the scenario description. Every other player turns a card and consults the missile damage value. The result is the player's Fleet Tactics skill, except that a result of 6 is treated as a 4 and a result of 1 is treated as a 3.

HIDDEN DAMAGE

In the basic game, the Damage marker is placed on the vessel and both players can see the result. Hidden damage puts considerably more suspense into the game, but requires a higher level of honesty by both players.

When a damage result is drawn, the player examines it and then places it on the affected ship counter result side down, so that only the explosion graphic is visible. The results of the damage are implemented normally, but the opposing player is not told the result.

Duplicate Damage markers are still returned to the draw pile or cup (face-down), and Ship Explode results are still immediately obvious to all players (as the affected ship is removed from play and replaced with a White Out-2 marker).

REFEREE

When **Battle Rider** is used as part of a **Traveller: The New Era** roleplaying campaign, there will obviously be a referee present. The presence of a referee allows many interesting variations to be played.

Double Blind Play: In this variation, only the referee is allowed to look at the map, and the referee coordinates all detection tasks by the players, only telling players what ships have been detected and their course and vector. (A piece of blank hex paper is very useful for this.) In addition, damage and hit cards are turned by the referee so that the firing player does not know whether a shot hit or what damage has been done, except by watching the subsequent performance of the vessel.

Scanning for Damage: Getting detailed data on what is going on within an enemy vessel is impossible at ranges of greater than one hex. The referee may allow players to scan enemy vessels in the same hex for life, functioning power plants and weapons, etc. Such tasks will require the integrated use of active and passive sensors. These sensor rolls will be uncertain tasks, and the information that the referee reports to the sensing player may or may not be true.

LARGE SCENARIOS

Battle Rider is designed to allow multiple-ship and squadron-sized actions, but it is still possible to bog it down with numbers, particularly in the area of missile fire and damage. The following optional rules will assist play in larger scenarios.

Missile Barrages: When large numbers of missiles are fired at a particularly well-defended ship, the resolution of anti-missile fire and then the fire of the missiles can take a long time. To speed play, divide the missiles up into a series of "barrages." The number of missiles in each barrage need not be great (two missiles per barrage will cut the amount of card turning in half, for example), but should be mutually agreeable to both players.

Each missile in a given barrage must be attacked with exactly the same defenses (such as three lasers per missile) and one card turn determines the effect of all fires against the barrage (that is, all hit or all miss). After laser fire, the surviving barrages are attacked by dampers (using the same rule), and then the surviving barrages are hit by sandcasters. One card is then turned per barrage to determine if it hit, and then one card is turned per barrage for damage, with that damage card applying to each missile in the barrage. If there are relatively few missiles surviving after the damper fire round, individual damage card may be turned for each missile which hits.

Damage Results: In a large scenario it is fairly easy to exhaust the supply of Damage markers, or at least deplete them sufficiently to make certain results much higher probability than normal (particularly No Effect and Ship Explodes). While additional marker sheets are available from GDW (and we will cheerfully sell you as many as you would like), a less expensive alternative is to substitute a die roll or card turn for damage instead of a random marker draw.

Roll two 6-sided dice, add the result, and consult the following table. (If no dice are available, turn two cards and add the missile damage values shown together.)

No.	*Result*
2	Bridge Destroyed
3	Fire Control
4	Power Plant
5	Sensors
6	Life Support
7	Roll Again
8	Artificial Gravity
9	Jump Drive
10	Maneuver Drive
11	Spine
12	Computer

Roll Again: Roll one 6-sided die (or turn one card and consult the missile damage value). On a result of 1-5, there is no effect; on a result of 6, the ship explodes.

Task Force Composition Chart: With large numbers of ships in a task force, and with several Damage markers on one or more ship, the stacks of counters can become fairly precarious. If this becomes a problem, photocopy the next page and use it as a play aid. Place the ships of a large task force in the box once they are detected and begin to take damage.

FACING

The facing of spacecraft plays a limited role in **Battle Rider.** In general terms, spacecraft must face in the direction that they are *accelerating.* Note, however, that if a spacecraft is not accelerating (i.e., firing its maneuver engines to speed up, slow down, or change direction), its facing has nothing to do with its vector (i.e., the direction and speed at which it is coasting through space). Like a leaf floating down a stream, it may freely spin or point in any direction desired, regardless of its vector.

Facing Limits Based on G-Turns Expended

When deciding on a craft's facing, the player must first determine the craft's base facing for the turn, and then determine the amount of allowed deviation from that base facing.

Base Facing: If G-turns were used for thrust, the base facing is the hexside opposite that containing the ship's Thrust marker. If G-turns were used for maneuver and evasion, use the base facing for the maneuver, and proceed to the next step.

If G-turns were used for evasion only, or if no G-turns were used for any purpose, there is no base facing—see next step.

Deviation: Once the base facing is established, determine the amount of leeway to either side of that facing that the player has when choosing the craft's facing for the turn.

Deviation is determined by the number of G-turns used for maneuver (not evasion) as a proportion of the craft's G-rating.

- If G-turns equal to the G-rating were used, final facing *must* be the base facing.
- If G-turns equal to more than half of the G-rating but less than the full G-rating were used, final facing must be the base facing or either of the adjacent hexsides.
- If G-turns greater than 0 but less than half of the G-rating were used, final facing may be any hexside *except* the one containing the Thrust marker.

No G-Turns Spent: In cases where there is no base facing because no G-turns were spent, the player may select any facing for the final facing.

Evasion: In cases where G-turns were spent for evasion (whether the evasion roll was successful or not), the base facing is determined randomly. Turn a card and multiply the missile damage value shown by 2. Consult the Heading/Facing Compass on the map. The result is the direction of facing. For every maneuver G not spent for either maneuver or evasion, the player may adjust the final facing one hexside from that determined by the die roll.

The only exception to random facing determination for evading spacecraft is in the case of Outstanding Success at the evasion task. In this case, the vessel's commander has succeeded in maintaining facing control even while successfully complicating enemy sensor and fire tasks: The player may select any facing for the final facing.

Facing Effects on Combat: Spinal mount weapons may only fire across the facing hexside. Trace a line from center of firing hex to center of target hex to determine if the target is in the spinal mount's arc of fire.

Task Force Composition Chart

BOARDING ACTIONS

Disabled enemy ships may be boarded. Disabled ships have no functioning power plant or maneuver drive. Unfortunately, there is no way to tell whether an enemy vessel is disabled or playing possum.

In order to board, the boarding vessel must match vectors with the disabled ship. On the turn following matched vectors, boarding may begin in the Initiative Phase. Once a boarding party is sent to a disabled ship, the boarding ship conducts all tasks with a +1 Diff Mod due to crewmembers away from their stations.

Procedure: Assuming that a vessel is disabled, the boarding action takes place. The ship size modifier multiplied by –1 (i.e., the modifier with the value of the sign reversed) is the number of hull sections on the boarding and boarded ship. (Ships with a size of –1, 0, +1, and +2 all have a single hull section, but the reversed sign of their size value is still used as a modifier below.)

Each game turn, during the Initiative Phase, the boarding and boarded player each turn a card, consult the missile damage value, and add the following modifiers (Mods):

± hull size (with sign reversed)
+1 first turn of attack
+1 if defending
+1 if lost the previous turn

The player with the higher adjusted value captures one hull section, except that a side which took the +1 defending Mod does not take any additional hull sections. If the values are tied, neither side captures a hull section. The boarding player may never take the +1 defending Mod. The boarded player may forego the defending Mod for the purpose of recapturing a previously captured hull section. Note that whichever side *loses* in a turn receives a +1 Mod the next turn.

Combat continues until all hull sections belong to one side or the other. (Note that the boarding player must win the first turn of battle or the boarding action fails.) If the boarding side wins or loses, the survivors may return to their own vessel (and the +1 Diff Mod is ignored). If the boarded side loses, the crew is captured. The boarding crew may remain on board the captured ship to secure it or repair it, or they may return to the boarding ship and re-man their stations, at the player's option.

SURPRISE

Surprise is determined only once per scenario. Surprise is possible for either side, and the element of surprise gives an advantage both in attacking and in avoiding the enemy. In some cases, surprise is indicated in the scenario instructions, but it can also be determined by the players.

Surprise is a task with a base difficulty level of 5 and –Diff Mods equal to the player's Fleet Tactics skill. It is attempted by the side which first detects an enemy vessel.

Benefits of Surprise: The side which was surprised may not maneuver or fire on the first turn it was surprised, unless it is able to man battle stations. Manning battle stations is a task with a base difficulty level of 4 and no Diff Mods (but using Crew Quality, if applicable). Battle stations are always manned on the first full turn following surprise.

Readiness: Under certain circumstances, players or scenario instructions may stipulate that their vessels are operating at alert status, with some battle stations already manned, or at battle stations. If operating under alert status, the task to man battle stations is one difficulty level easier (–1 Diff Mod). However, these levels may not be maintained indefinitely without fatiguing the crew. Alert status can be maintained for only three consecutive four-hour (eight-turn) periods (a total of 24 turns) before crew fatigue degrades performance. Each additional consecutive four-hour (eight-turn) period beyond these limits imposes a +1 Diff Mod on every task attempted by every crewmember.

Thus, if Captain Queegulii kept his crew at battle stations for 20 hours, beginning at 12 hours and one minute (or turn 25), all tasks would be one difficulty level higher. Beginning at 16 hours and one minute (or turn 33), all tasks would be two levels higher. These penalties remain in effect until at least three consecutive periods (12 hours, or 24 turns) are spent at condition 0. So, in the example, if Queegulii let his crew stand down after 20 hours, but called them back to battle stations after only four hours, they would still perform their tasks at two difficulty levels higher.

In addition, once the crew has returned to normal cruising status, the task attempt to man battle stations is increased in difficulty if the crew had been standing at alert status or battle stations for a long period of time. For each consecutive period at battle stations or two consecutive periods at alert status, the roll to man battle stations is increased in difficulty by one level (+1 Diff Mod). This penalty is decreased by one level for each subsequent period spent at normal cruising. Thus, a crew which had been at alert status for four consecutive periods (16 hours) would be at +2 difficulty levels to man battle stations during the first period after they stood down, +1 level the period after that, and back to normal after two full periods of normal cruising.

RESTRICTED FIRE CONTROL

Some vessels have sophisticated fire directors but do not have enough to guarantee that all weapons will have access to them in the heat of battle. All ships are assumed to have a fire director for their spinal mount (if any), but may have only limited number of other directors. The number listed below for vessels in the game is the number of fire directors available for each battery in each phase. Each fire director can engage one target with one or more weapons of the same type and printed range and allow those weapons to ignore the standard fire control Diff Mods. Once all of the available fire directors have been used, additional fire is conducted without benefit of the ship's fire control rating.

The following vessels in the game have limited fire directors if this optional rule is used:

Vessel	*Directors*
Ashtabula	2
Aurora	1
Chrysanthemum	1
Fiery	1
Gazelle	1
Kinunir	1
Maggart	1
Mary Ellen Carter	1
Midu Agashaam	1
Patrol Cruiser	1
Shukugan	1

INTEGRATION WITH TRAVELLER: THE NEW ERA

Battle Rider is intended to stand alone as a game and not presuppose knowledge of the **Traveller: The New Era** roleplaying game. However, many **Battle Rider** players will also be players of the roleplaying game, and will use it to resolve situations that occur in their roleplaying campaigns.

Fleet Tactics: A player character's **Battle Rider** Fleet Tactics rating is his or her Fleet Tactics asset divided by 3, rounding fractions down.

Crew Quality: When a ship manned by player characters is used in **Battle Rider**, all tasks should be resolved using the crew's actual assets and using the standard D20 die roll for task resolution. Task difficulty numbers in **Battle Rider** (BR) correspond to the following difficulty levels in the roleplaying game (RPG).

BR	*RPG*
1	Easy
2	Average
3	Difficult
4	Formidable
5	Impossible

The following **Traveller** assets are used for defined tasks in **Battle Rider.**

Task	*Asset*
Control missile/drone	Gunnery (Missile) or RCV Operations
Crash-start power plant	Ship's Engineering
Damage control	Ship's Engineering or Electronics
Defenses	Screens (appropriate cascade)
Evasion	Ship's Tactics
Fire	Gunnery (Energy Weapons)
Jam sensor	Sensors
Land/take-off from planet	Pilot (Interface/Grav)
Man battle stations	Leadership
Detect/fire control lock	Sensors
Surprise	Fleet Tactics

Evaluating Ships

Ships designed using **Fire, Fusion, & Steel** or published in other **Traveller** products may be converted easily to **Battle Rider** ships. Use any counter or appropriate miniature to represent the ship on the map and make a separate data card for the ship in the same format as the back of a counter. 3"x5" index cards cut in half are useful and about the right size for this.

Identity: The name, class, and type of ship are entered here. This information is provided by the published design or made up by the designer.

Size: The size modifier of the craft is based on its total displacement. Consult the following chart and record the appropriate value. If the vessel is equipped with socket extenders, add the notation "E" after the size value.

Tons	*Size*	*BR Size*
less than 1	Sub-Micro (SM)	+2
1+	Micro (Mc)	+1
10+	Very Small (VS)	0
100+	Small (S)	–1
1000+	Medium (M)	–2
10,000+	Large (L)	–3
100,000+	Very Large (VL)	–4
1,000,000+	Gigantic (G)	–5

Tech Level: The tech level of manufacture.

Beam Weapons: Beam weapon values are recorded in the appropriate data fields. Type is noted by a standard letter code (L for laser, M for meson gun, P for particle accelerator) in parentheses following the type record the number of guns firing (if more than one) and what Diff Mods they ignore based on overpowering. Numbers of weapons are preceded by an "x" while Diff Mods ignored are preceded by a "–."

In the case of spinal mounts, the number firing is the total number (usually, but not always, 1) installed to fire along the main axis of the vessel. In the case of all other batteries, the number firing is the total number installed on the vessel divided by the absolute value of the ship size modifier (with size value of 0, +1, and +2 all treated as 1), rounding all fractions to the nearest whole number. In other words, the larger the vessel, the fewer guns per battery, but the more total batteries.

In the case of overpowering, values are written here only if the ship has sufficient excess power to run all systems and overpower the weapons simultaneously. If five times the power necessary to fire the weapon is available, record a –1 in this space; if 10 times the power necessary is available, record a –2.

After the number and Diff Mod codes, write down the short range in hexes, a colon, and then the damage at each of the four ranges of the weapon. Separate each range with a dash. If the weapon has the same damage at all ranges, simply write the number once.

Standard **Traveller** damage is converted to **Battle Rider** damage using the following Damage Conversion table.

Damage Conversion

Traveller	*Battle Rider*
1+	0
20+	1
40+	2
80+	3
120+	4
160+	5
200+	6
250+	7
300+	8
400+	9
500+	10
750+	11
1000+	12
1250+	13
1500+	14
1750+	15
2000+	16
2500+	17
3000+	18
3500+	19
4000+	20
4500+	21
5000+	22
6000+	23
7000+	24
8000+	25
9000+	26
10,000+	27

Fire Control: The number of Diff Mods ignored when firing at a target. This is determined by the tech level of the installed master fire directors and is the same value as in conventional **Traveller** ships.

It is assumed for purposes of the game that all ships have sufficient master fire directors to engage multiple targets. This is the case if the ship has (in addition to any missile fire directors) one fire director for every meson gun and particle accelerator and one for every two lasers mounted.

If it has fewer than that, total the number of non-missile fire directors, subtract the number of spinal mount weapons available, and divide the remainder by the number of batteries on the vessel (as determined by the ship's size code). Record this number in parentheses after the ship's fire control Diff Mod value. This is the number of fire directors available to service the weapons of a single battery in a single phase.

If there are fire directors for missiles and/or spinal mounts but none extra for beam weapons, the ship still has a fire director rating of 1, as it is assumed that a director can be "borrowed" to direct fire from a battery.

Each fire director may engage one target with one or more weapons of the same type and printed range and allow those weapons to ignore the standard fire control Diff Mods. Once all of the available fire directors have been used, additional fire is conducted without benefit of the ship's fire control rating.

Sensors: These are listed in the order active sensor (A), passive sensor (P), and jammer (J). Use the best sensor of the type available to determine the ship's rating. (Jammers are sensor jammers, not communication jammers.) After the sensor type, make a colon and then record the sensor's short range. If the ship has an EMM package, just write "Msk" at the end of this line.

Structure: The main entry here is the ship's armor value (AV). Armor value for **Battle Rider** is calculated using the standard **Traveller** armor value and consulting the Damage Conversion table at left. If, for example, a ship had a **Traveller** armor value of 143, it would have a **Battle Rider** rating of 4.

If the ship has an auxiliary bridge, that is noted here as well.

Screens: These are active defensive systems and are listed in the order meson screen (MS) and value, sandcasters (SC) and number mounted, and nuclear dampers (D) and number mounted.

The value of the meson screen is calculated by taking its **Traveller** protection value and consulting the Damage Conversion table at left. If, for example, the screen had a protection value of 2200, it would have a **Battle Rider** rating of 16.

Sandcasters and nuclear dampers are divided into batteries, using the same procedure as for beam weapons, and the number in a single battery is recorded here.

Missiles: If the ship has missiles, write "Msl:" in this field, followed first by the number of missile directors on the ship and then (in parentheses) by the number of ready missiles carried. The number of ready missiles is the sum of all missiles carried in turrets, barbettes, and bays, but not counting any reloads carried as cargo.

Maneuver: This data field covers both interplanetary and interstellar travel capabilities. The first entry (in parentheses) indicates whether the ship can skim (S) and/or process (P) fuel from a gas giant. Next comes the interstellar jump drive (J) capability, if any, and finally the maneuver drive ratings in Gs of acceleration per turn (G).

A ship must have at least 20 G-hours of fuel if it has a maneuver drive. Ships with less than 50 G-turns of fuel have limited maneuver fuel. Note this by placement of an asterisk after the G-rating.

Battle Riders: This lists the number of battle riders (BR) or light battle riders (BRL) carried by the ship.

Point Value: This is the point value of the ship used for victory determination and and scenario generation. To determine the point value of a ship, divide its gross tonnage by 1000, extract the square root, and multiply the result by the tech level of construction. The result is the ship's point value.

Battle riders have two values separated by a slash. The first value is the value calculated above (based on simple tonnage and tech level). The second value is the first one multiplied by 1.5, and is used if the vessel is purchased without a tender.

Tournaments

GDW will periodically sponsor **Battle Rider** tournaments for the summer convention season beginning in 1995. These will involve dogfights between two or more players who have equipped themselves on a fixed-point budget and other technological constraints. Ships and weapons published by GDW will be eligible for these tournaments, as well as those designed using the ship design sequence in **Fire, Fusion, & Steel.** However, all such homemade designs must be submitted to GDW and approved before they can be used, at which time they may be used by any entrant. All details will be presented in issues of **Challenge,** The Magazine of Science-Fiction Gaming.

DESIGNER'S NOTES

These notes should properly begin where the thinking for the design began, and that is with the damage system. **Battle Rider** is clearly intended to be a simplified and streamlined alternative to **Brilliant Lances**. Because **Brilliant Lances** is designed to provide the detailed combat and damage resolution the ship-to-ship combat requires when player characters are manning the key battle stations, it obviously covers a level of detail that is inappropriate to fleet actions, and the more successful **Brilliant Lances** is at its design goal (and we think that it's very successful), the less suited it is to larger actions. Much of the fine-grained detail of **Brilliant Lances** is contained in the damage system, and so that's where I started to look when I began work on **Battle Rider.**

My first instinct was to simply do away with hit locations, subsystems, and minor damage. All damage would be expressed in terms of major damage hits and divided randomly among the major ship systems (engineering, life support, etc.). After a fairly short time, I became dissatisfied with this because it seemed to have the worst of both worlds; it lost most of the detailed feel of damage in **Brilliant Lances** but still required lots of paperwork to keep track of damage on big ships (which can take a huge number of major damage hits to some systems).

Fairly quickly my attention turned to critical hits, and I began looking at what killed most ships (especially big ships) in most scenarios. Not surprisingly, it was critical hits. As a result, I keyed the damage levels of weapons to what was necessary to cause a critical hit and just ignored everything else. Because of the variety of critical hit possibilities, this actually keeps a nice mix of damage types while greatly streamlining play.

My next step was to keep paperwork to an absolute minimum. (My original goal was to eliminate it altogether, but that proved impossible. More on why later.) The first target for paperwork reduction was the vector movement system. We had decided with **Brilliant Lances** to go with a heading plus velocity vector system, for reasons which aren't important here. That kept markers off the map but meant that each ship needed a written record of its vector. For large fleet actions that just wasn't practical, so I went with the marker system we originally used in the old **Triplanetary** and **Mayday** boardgames. This puts some markers back on the map, but eliminated part of the paperwork. The simplified damage system, once I went to markers in place of a die roll and had players just place the marker on the ship, enabled a lot more paperwork to be dumped. Printing all of the key game statistics of each ship on the back of the counter eliminated almost all of the rest.

The last remaining piece of paper in the game is the Missile Spread Sheet, and that proved nearly impossible (and certainly impractical) to dispense with. All of the functions of the Missile Spread Sheet could be done with counters, but it would require at least one additional counter sheet and would clutter up the playing surface a lot more than one little piece of paper. As a result, I decided to stick with the Missile Spread Sheet.

While we're on the subject of missiles, some word about their treatment in the game is in order, as it differs from the way they function in **Brilliant Lances** and the core **Traveller** rules. In those rules, each missile causes 1D6 separate hits, each with a damage value of about 2 (in **Battle Rider** terms). While I was willing to ignore cumulative damage that is less destructive than a critical hit in most cases, to do so for missiles would render them impotent against any ship with a size modifier of –3 or –4, and against any size –2 ship with an armor value (in **Battle Rider** terms) of 10 or more. Not only was that not an accurate portrayal of their effects, it also wasn't very much fun from a game point of view.

As a result, I made the die roll (or card turn in this case) determine the cumulative level of damage of all the shots combined, but to avoid overstating the level of critical damage, I reduced it to a 1-6 range (instead of a 2-12 range, which it would have been simply adding the number of DV-2 hits generated). The result is a compromise that I think adds a lot to the enjoyment of the game.

My next priority was to come up with a game system which, while remaining faithful to the physics involved, was decision-driven and tactics-driven rather than simply science-driven. To that end, Dave Nilsen and I bounced a lot of ideas back and forth and finally came up with the current mix of game elements incorporated in **Battle Rider.** The back-and-forth nature of the operation rounds keep the players alternating actions and reacting to each other throughout the game turn, which was a high priority. Since fire isn't simultaneous, players are continually making tactical decisions throughout the game turn that affect the outcome of the battle, and influence the decision both players make later in the turn.

I also wanted the much-ignored Fleet Tactics skill to be a force in the game, but at first had trouble visualizing what affect it had on play. Our traditional view of it is some sort of intuitive ability to second-guess your opponent, which is tough to write a rule about since that's what both players in a game try to do by their playing styles. Finally, I began thinking of this intuitive style of play as an *innate talent,* and began exploring what Fleet Tactics might be if it were treated solely as an *acquired skill.*

What we came up with was the ability to command a task force (or several task forces) of vessels and have them operate as a coordinated single entity without ramming or shooting each other. That was easy to incorporate into the game by making it the maximum number of ships in a task force. That maximum number of ships has an important, if subtle, effect on game balance once combat begins. Given two equal-sized fleets, one commanded by an admiral with a Fleet Tactics level of 2 and the other with a Fleet Tactics level of 3, the second fleet can fire all of its vessels before the first fleet can fire two thirds of its own. Given that fire is not simultaneous, that can be an important edge.

Of course we then built in a little of the innate talent side of Fleet Tactics as well by tying the number of dummy task forces to the Fleet Tactics skill level.

Finally, a word about the advanced scenario generation system. Those of you who played **Seastrike** many years ago will probably recognize the inspiration for this system. The main thing that most naval encounter battles in game formats lack (and space combat games are usually naval games at heart—this one certainly is) is the sense of fear and confusion that comes with facing a largely unknown force. This scenario design system is designed to put that fear and confusion, that edge, back into the battle. You will never know what you're up against, and often won't know what you have to do to win, until it's too late. Sometimes you won't even know whether you've won or lost until it's all over. It's almost impossible to just play the victory conditions, and so players will have to do something they aren't very often called on to do—they will have to rely on their instincts and intuition, and will have to do everything they can to confuse and mislead their opponent.

While the victory goals of one player usually change as the opposition increases or decreases, we make no claim that all of the situations generated by this system are "balanced," nor do we offer any apologies on that score. Life is not always balanced, and the knowledge that it necessarily will be is another luxury no naval commander enjoys. Sometimes you're just stuck in a lousy situation and you have to do the best you can. Unlike your real-world counterparts, however, you have the advantage of knowing that there will always be another battle, and next time the shoe may be on the other foot.

BATTLE RIDER CARDS

The following list provides the actual values in each data field on each card in the game. If a card is lost, use the blank card to make a replacement.

No.	Hit	Crack	Double	Green	Missile
1	1				1
2	1				2
3	1				3
4	1				4
5	1				5

Battle Rider™

Errata & Clarifications — June 22, 1994

Counter Values

Several counters have incorrect numbers of weapons listed on their reverse side.
LT Maggart-1: The correct total for lasers is 4 (not 8). The correct total for sandcasters is 2 (not 4).
LC Maggart-2: The correct total for lasers is 5 (not 10). The correct total for sandcasters is 3 (not 6).
LM Aurora-1: The correct total for lasers is 4 (not 10). The correct total for sandcasters is 2 (not 4).
LC Aurora 2: The correct total for lasers is 5 (not 10). The correct total for sandcasters is 3 (not 6).

Note that in all cases except the LM Aurora-1, the value listed is the total number of lasers and casters on the vessel and the number which can fire into any one hexside (because of the socket extenders used on these vessels).

MISSILE CHARACTERISTIC CHART

Type	*Gs*	*Size*	*Sensor*
Controlled Missile	G:12	+2	—
TL-12 Semi-Ind	G:9	+2	P:1
TL-14 Semi-Ind	G:7	+2	P:3

CALCULATING DAMAGE VALUES
Laser DV = weapon DV, +/– target size, – sandcaster hits, –target armor value+10*
Particle Accelerator DV = weapon DV, +/– target size, – sandcaster hits, – target armor value
Meson Gun DV = weapon DV, +/– target size, – meson screen value**

* When calculating laser damage, divide target armor value by 10, dropping all fractions.
** The meson screen value is only subtracted from the weapon damage value on a failed meson screen task attempt. On a successful task, the meson gun shot misses and causes no damage at all. The meson screen value, when subtracted from the firing weapon's damage value, may never reduce the damage value to less than 0, provided it was greater than 0 after addition/subtraction of target size.

DAMAGE SUMMARY
Bridge: May not maneuver or evade, enter jump space, attempt detection, jam, operate screens, or use fire control to negate Diff Mods. Fire control locks allowed at +2 Diff Mod against already detected targets. If auxiliary bridge is available, effects of hit are temporary. (A second Bridge hit in the same scenario is permanent.)

Fire Control: May not fire energy weapons or missiles.

Power Plant: May not maneuver, evade, jam, attempt detection using active sensors, use screens (meson or black globe), or fire energy weapons. (Missiles and sandcasters may be fired and passive sensors used at +1 Diff Mod.)

Sensors: May not jam or attempt detection. Fire control locks allowed at +2 Diff Mod against already detected targets.

Life Support: All future tasks performed at +1 Diff Mod.

Ship Explodes: Remove ship from play.

Artificial Gravity: May not spend more than 2 Gs to maneuver, may not evade at all.

Jump Drive: May not enter jump space.

Maneuver Drive: May not maneuver or evade.

Spine: May not fire spinal weapon. For each G of maneuver or evasion thrust used, turn a card to test for tumble. Avoid tumble on a base difficulty of 2. (Crew quality counts.) If 2 or more tumble cards are turned, severe tumble results. If tumbling, +1 Diff Mod on all tasks. If severe tumble, +2 Diff Mod on all tasks. Next Operations Phase is spent correcting the tumble. No maneuver or evasion allowed, and Diff Mods still in effect until end of Operations Phase.

Computer: May not launch small craft or enter jump space. All other tasks performed at +1 Diff Mod.

No Effect: Damage has no effect on ship performance.

In the 57th century, travel between the stars has long been an accepted fact of life. Starships with powerful jump drives form the basis of interstellar commerce and the warships that protect that commerce.

But jump drives are bulky and take up volume that could be filled with defensive systems or offensive weaponry. A specialized vessel, optimized for large fleet actions, gained popularity during the Second Imperium and came to completely dominate the fleets of the Third Imperium. These vessels had no jump drives, had nothing in fact not directly related to producing the most effective line-of-battle combatant possible.

They were carried across the interstellar distances by huge jump tenders, vessels with little or no combat ability of their own, which would release their deadly cargo before the battle began and then withdraw to a safe distance. These warships became the very symbol of large fleet actions. Because they were carried from star to star, they were called battle riders.

Battle Rider™ is the game of squadron and fleet combat in GDW's **Traveller®** universe. **Brilliant Lances**™ brought you detailed starship combat designed for roleplaying interaction. **Battle Rider** gives you fast-moving fleet combat without the need for roleplaying levels of detail.

BATTLE RIDER™

GAME FEATURES

- Streamlined mechanics allow squadrons of capital ships to duke it out.
- Interactive game turn sequence and hidden task force rules emphasize decision-making, tactics, and bluffing instead of game mechanics.
- Unique diceless game system utilizes battle resolution cards for all sensor, evasion, and firing tasks.
- Task force rules and target endpoint markers allow vector movement with no paperwork.
- All ship characteristics (weapons, defensive systems, maneuver, etc.) are printed on the ship counter backs. No need to refer to a data book or off-map ship record sheet. No data forms to fill out prior to play.
- Key system and "mission kill" approach of the damage system allows detailed combat results with all damage recorded with markers on the ship counter, eliminating off-map damage records.
- Game system remains faithful to all aspects of the **Traveller** physical universe, and can as easily be used to fight out individual small ship battles as fleet actions.

GAME COMPONENTS

366 full-color game counters (three full counter sheets), ranging in size from 1/2-inch to 1 1/3-inch.
3 large 22-inch × 34-inch hex maps compatible with the maps in **Brilliant Lances**. The giant 2-inch hexes are big enough to use miniatures in place of counters.
96 battle resolution cards.
2 game reference charts
1 rules and scenario book.

FIRE, FUSION, & STEEL

Fire, Fusion, & Steel (FF&S) is the technical architecture manual for **Traveller.** It enables referees and players to design major items of equipment to meet the specific needs of their games. It is also meant to explain the genuine scientific basis of the equipment in the game, where such basis exists, and provide the fictional rationale for other technical items. We do this because we believe that, to the extent possible, a science fiction game ought to be grounded in real science. Of course, the game isn't just science, it is science *fiction*, and so the technology used in the game departs from reality in a number of significant areas. But it only does so where required by the necessities of high adventure. We believe firmly that a grounding in solid science for much of the game's technology adds to the sense of realism, the "willing suspension of disbelief," so important to enjoyable roleplaying.

Beyond those goals, this manual also enables referees to tailor the **Traveller** rules to fit a variety of other possible science fiction universes with different departures from scientific reality. While this gives unprecedented control of the game environment to the referee and players, it poses some problems for the organization of this book.

For purposes of clarity, the environment in which **Traveller: The New Era** is played is called *Imperial Space* throughout this book. It represents not a specific astrographic area, but rather the specific future history detailed in the game, along with the technological reality of that future history. The assumption of this book is that the vast majority of users will, at least initially, be using it to design Imperial Space technical equipment. As a result, each chapter of the manual is organized with all Imperial Space technologies first, and incorporated directly into the various design sequences. Then a section covering alternate technologies is provided at the end of most chapters which details alternative technological approaches to the issue addressed by the chapter.

The manual itself is divided into three broad areas, or "books": Major Systems, Subsystems, and Weaponry. By major systems we mean vehicles and craft of various sorts which incorporate a large number of subsystems in their design. The design sequences for these major systems include tables and subsystems unique to the major system (such as tracked suspensions in the Ground Vehicle chapter), but will refer you to subsystem chapters (such as Life Support or Electronics) for material common to a number of different major systems. Weaponry could be included in subsystems but constitutes such a large body of material as to justify its own section of the book.

We hope that this organization proves to be the most useful in the long run.

Special Note: It was our original aim to make this manual complete under one cover. In the course of preparing the book, however, it became clear that that simply was not possible. A science-fiction game should always be open to additional technological treatments, and no one book should ever impose absolute limits on what the game can cover. We've covered the most important subjects in this manual, but look for treatments of additional subjects ("wet" ships, robots, disintegrators, neural weapons, primitive transport, genetic engineering, jump projectors, etc.) in future products. When a sufficient number of these have been published, they will be gathered into a single follow-on volume.

The Metric System of Measure

The **Traveller** game exclusively uses the metric system of measure. Those players from countries (such as our own) which still cling to the archaic English system of measure have our sympathy. For you we present the following summary of the major metric units commonly used in the game, an explanation of what they mean, and an approximate conversion system.

The conversion system is by no means precise, but is instead intended to provide a rough feel for equivalencies.

The metric system is a decimal system. Each area of measurement (distance, volume, power, energy, etc.) has a base unit of measure (meter, liter, watt, joule) and all other units are either decimal multiples or fractions of that base measurement. Whether it is a fraction or multiple, and by how much, is indicated by a prefix attached to the base unit of measure. These prefixes are:

micro-	1/1,000,000
milli-	1/1000
centi-	1/100
deci-	1/10
deka-	×10
kilo-	×1000
mega-	×1,000,000

Distance

millimeter	about 1/25 of an inch
centimeter	about 2/5 of an inch
meter	about 1 yard (and 3 inches)
kilometer	about 3/5 of a statute mile, 5/9 of a nautical mile

Volume

liter	(1000 cubic centimeters) about 1 quart
kiloliter	(1 cubic meter) about 1 ton of water

Weight

gram	(weight of 1 cubic centimeter of water) about 1/30 of an ounce.
kilogram	2.2 pounds
tonne	(1000 kilograms, also called a metric ton) about 2200 pounds

Energy

joule	work done by a current of 1 amp flowing at a potential of 1 volt
megajoule	power produced by the explosion of between 6 and 7 ounces of TNT

Power

watt	1 joule per second
kilowatt	about 1 1/3 horsepower

Important Note: *Throughout this book, the word "tonne" always means a metric ton. A "ton" in its meaning of 14 cubic meters of volume will always be specified in the text as "displacement ton."*

Interpolation

The design rules will often allow you to design a component which falls somewhere between two entries on a table and direct you to interpolate the correct value. Interpolation is a method of determining a value which falls between two known values. As an example, look at the CPR Gun table on page 109, and assume we want to know the weight of a 7.62 cm gun. We know the weights for a 7cm gun (.54 tonnes) and for an 8cm gun (.66 tonnes).

To interpolate, first find out how far between the the two reference points your intermediate data point falls. This is done in three steps.

Step 1: Subtract the lower reference point from the higher reference point. 8cm–7cm=1cm.

Step 2: Subtract the lower reference point from the intermediate reference point. 7.62cm–7cm=0.62cm.

Step 3: Divide the result of step 2 by the result of step 1. The result will be a decimal value. 0.62÷1=0.62.

In the case of our example, the result will be 0.62.

Second, find out the the differences in values between the two reference points, by subtracting the lower value from the higher. In our example, the difference in weight is 0.12 tonnes.

Third, multiply the decimal value of the difference in data points times the difference in values and add the result to the lower of the two reference point values. In our example, we multiply 0.62 times 0.12 (product of .0744) and add it to the lowest data point value (.54) for a result of 0.6144. The 7.62cm gun weighs 0.6144 tonnes (614.4 kilograms).

TECHNOLOGY ASSUMPTIONS

Traveller: The New Era is intended to not be limited to a single campaign background or to a single set of future science assumptions. Its rules are intended as a framework that will allow the play of a wide variety of science-fiction visions. Such different visions have distinctive technologies that separate them from speculative universes without such technologies. Matter teleportation, stardrives, and antigravity are all forms of technology whose presence in or absence from a setting have a major influence on the overall feel of that science fiction setting, and are all directions that can be explored in **Fire, Fusion & Steel: Traveller Technical Architecture.**

However, like any roleplaying game, **Traveller** must have a basic set of assumptions which drive a basic campaign setting. Not all referees wish to design their own unique universes. Many would rather start playing in a standard campaign setting that they know will be supported by future products and source material. For **Traveller**, this standard campaign is the Imperial campaign that was started with the first **Traveller** edition. This campaign will continue to be supported as the standard default campaign of **Traveller: The New Era.**

The purpose of this chapter is to explain to referees and players how the technological assumptions of this standard Imperial campaign fit into the variable technology schemes presented in **Technical Architecture.** Players and referees who have no desire to use a campaign other than the Imperial campaign may still find this information interesting.

Different Universes

The approach taken by **Traveller: The New Era** is that each of these different technological visions are actually different universes. The different technologies seen in these universes are the result of differing physical laws. These physical laws will make certain technological breakthroughs more or less difficult, perhaps even impossible. The more a universe's physics resist a certain development, the longer it will take to make the initial breakthrough, and the more time will pass between successive improvements. Likewise, the physics of a universe will allow one form of stardrive to be developed, but not another—say the use of naturally occurring warp points instead of **Traveller**'s standard jump drive.

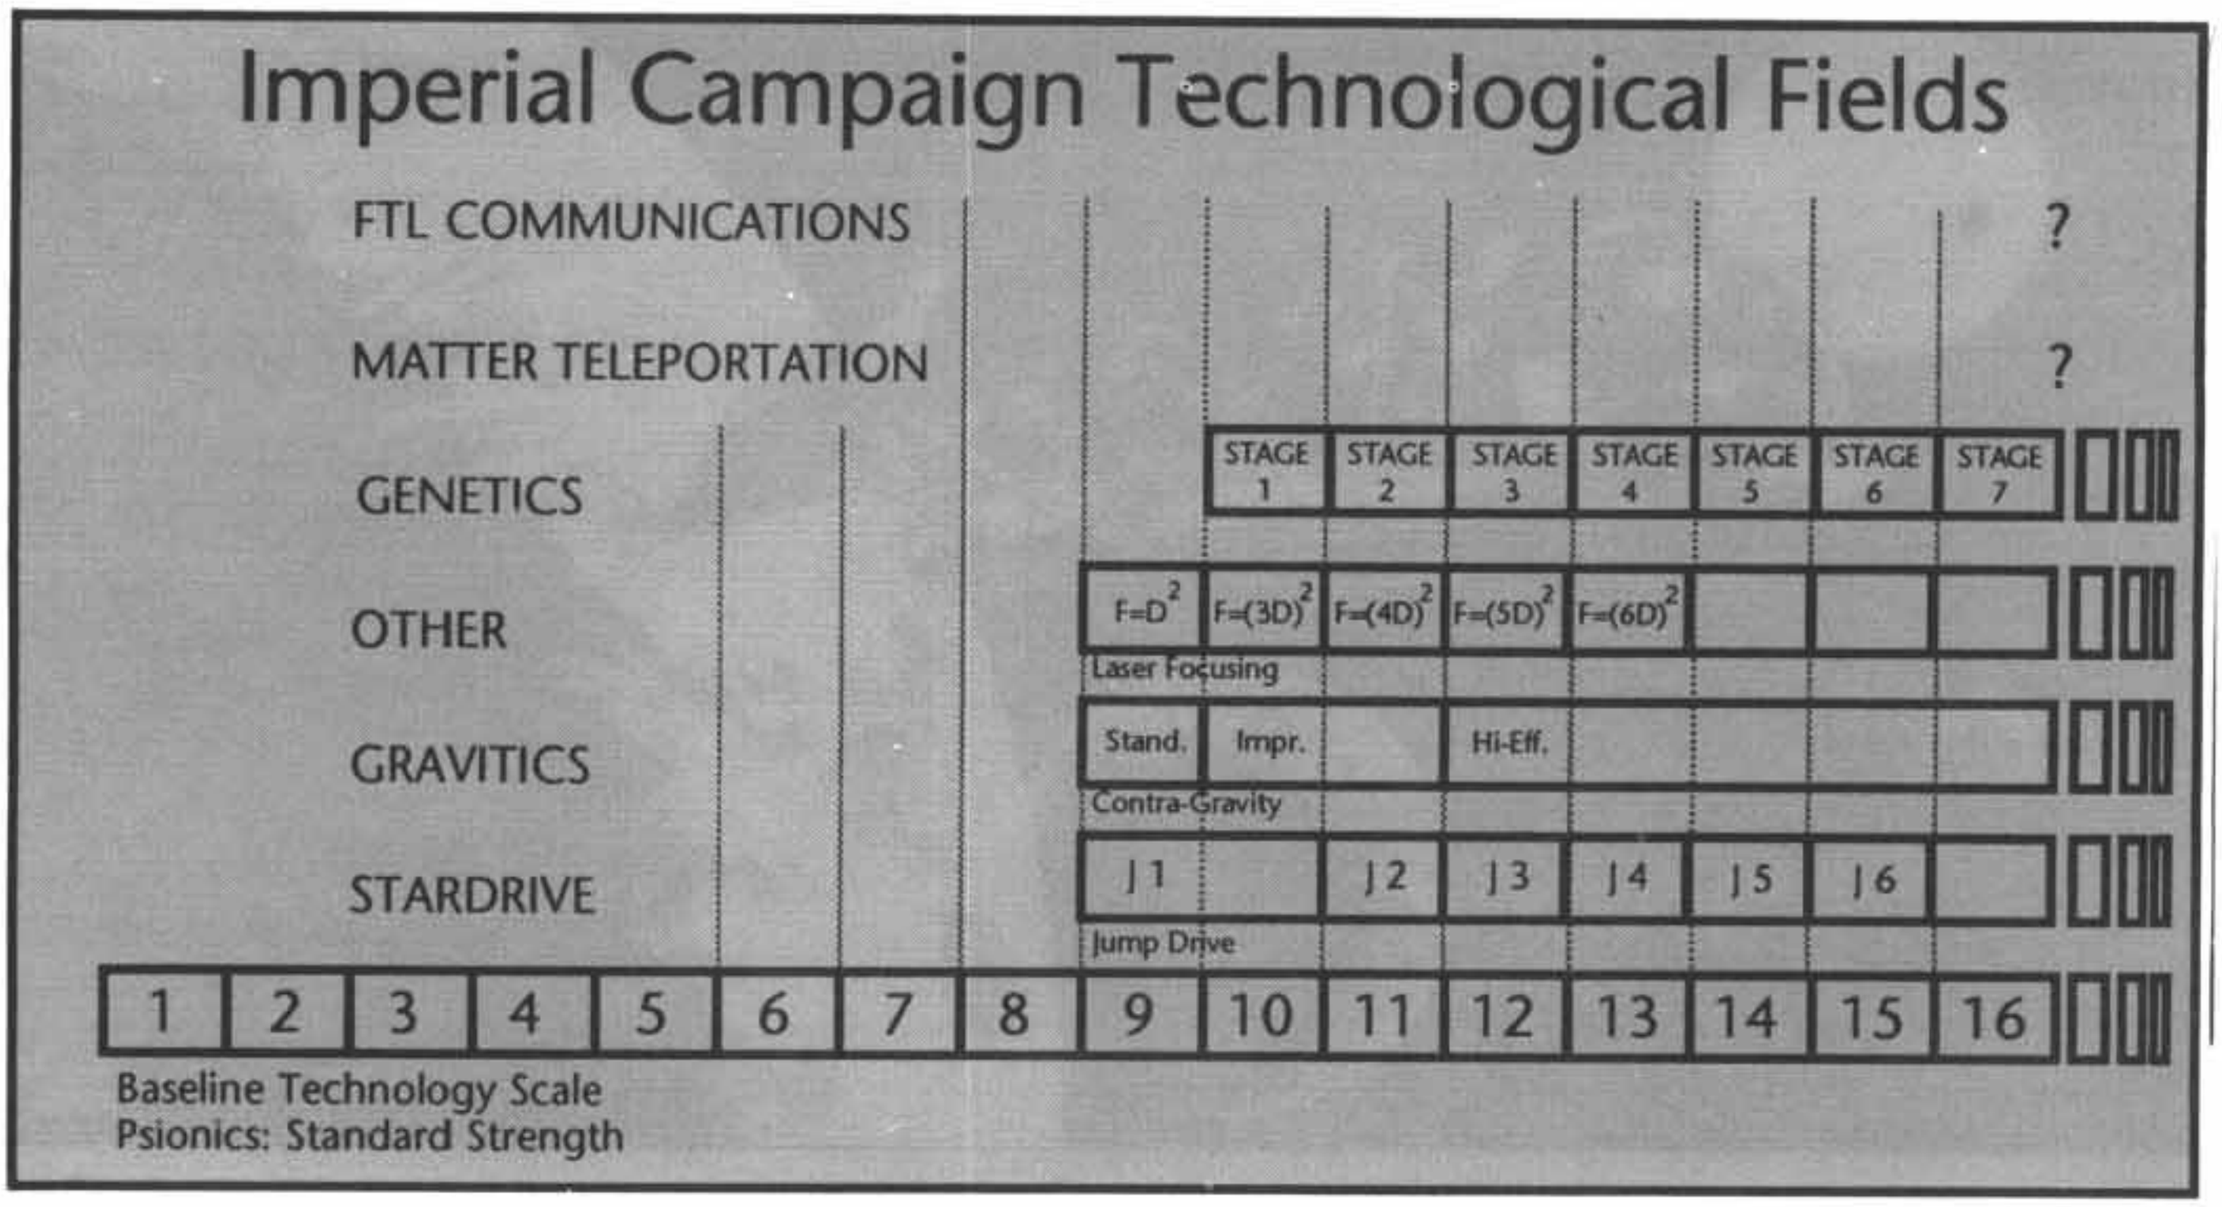
Traveller divides the technology of the future into two types: baseline technology and projected technology.

Baseline Technology: Baseline technology is technology based on physical laws that we understand and can effectively manipulate in the 20th century. This includes such things as firearms, internal combustion engines, nuclear fission, ballistic computers, etc. Baseline technology also includes one important set of extrapolated technologies: advanced power generation. The ability to create power of a certain quantity using a certain amount of fuel is the most important consideration for the use of any other technology, and hence is included in **Traveller**'s baseline technology. This particularly refers to the harnessing of fusion technology at ever increasing levels of efficiency. It is this baseline technology that defines the **Traveller** technology, or tech, level.

Tech Level: Tech level is a shorthand scale to show the level of baseline technology available. See the table for examples.

In different universes, different projected technologies may be added at different tech levels, indicating the point on the baseline scale at which they initially become possible. But not all projected technologies will be possible in a given universe, nor will they become possible at the same time as in other universes.

Note that baseline technology levels have fuzzy borders. Certain technologies become available as experimental systems before they are routinely useful and economically practical. Furthermore, the model of Earth history can be misleading when applied to an interstellar community, because worlds do not need to individually discover basic scientific principles. The best example is the discovery in Earth's history of microbes and the medical revolution that this brought about. A low-tech world would not have to develop its own microscopes to learn about these facts. Such a world would only have to be told about certain principles of infection and sanitation in order to realize the great health benefits that come from boiling water, maintaining standards of cleanliness, etc.



Also note that baseline technology allows unusual technical breakthroughs under specific local conditions. For example, on a world with a dense atmosphere and low gravity (an unlikely combination to be sure), practical aircraft will become available before they were on Earth, as it would be easier to generate sufficient power to keep an aircraft in the air.

Available Baseline Technology

Baseline Tech Level	*Period in Earth's History*	*Available Technology*
0	Stone Age	Fire, stone tools
1	Middle Ages	Wind power
2	c. 1600	Early firearms
3	c. 1800	Steam power
4	c. 1900	Internal combustion engines, electricity
5	c. 1930	Radio, radar, rocketry
6	c. 1950	Jet engines, nuclear fission
7	c. 1970	Low-power lasers, printed circuits
8	c. 1990	Fiber-optics, microchips
9	Beyond 2000	Fusion power
10+	Farther beyond	Increasingly efficient fusion power

Projected Technology: Projected technology refers to breakthroughs using physical laws not currently known (for example, stardrives and antigravity), or physical laws that we do know and understand to some extent, but which we do not yet understand how to completely manipulate (the cloning of higher animals is an example of this). Because projected technology deals with the ability to do certain things in a universe because the physical laws there allow it, projected technology also refers to things not normally thought of as technology, like psionics. Psionics is not a technology *per se*, but rather a natural phenomenon which can be exploited.

The Imperial Campaign as Example

In order to clearly explain these concepts, we will examine the technological underpinnings of the standard Imperial campaign. This campaign is a variant universe like any other described above. It has its own set of technological assumptions which reveal the background physics of the universe.

A universe can be thought of as having "settings" which dictate the sort of things that can and cannot be done in that universe, and how difficult these things are. The harder a certain technology is to perfect, the later it will be introduced on the baseline technology scale.

Looking at the technology chart above for the Imperial campaign, we see that, like any **Traveller** universe, it begins with the baseline tech level scale. To this baseline are added the projected technology fields.

Projected technology is divided into several different fields. Each field represents a solution to a problem or goal. For example, the stardrive field answers the problem of how people get from star to star. Some of these fields present alternative approaches to those goals. In the case of the stardrive field, a universe's projected technology can be jump drive, stutterwarp, natural warp points, star gates, hyperspace, or psionic shifting (as a rule of thumb, only one type of stardrive should be included in a universe). Other fields have just one approach and effect (matter teleportation, for example).

When a field is selected to use in a universe, it must be given an initial availability point in relation to the baseline tech level scale. For example, in the Imperial campaign, the stardrive type chosen, jump drive, becomes available at tech level 9.

After setting the tech level of initial availability, the field's "slope" must be set. Most fields will have scales of improvement within them (for example, jump drive availability starts out with jump 1, then advances to jump 2, jump 3, and so on). The slope determines how rapidly these improvements are made with respect to the baseline tech level. The standard 1:1 slope allows one of these improvements per baseline tech level. A shallow slope reflects the fact that each incremental improvement takes longer. A shallow slope could be designated by the referee as requiring two (a 1:2 slope) or even three (a 1:3 slope) tech levels per improvement. For example, if jump drive technology were placed on a 1:2 slope, jump 1 would become available at tech level (TL) 9, jump 2 at TL 11, jump 3 at TL 13, and so on. A universe might also have a steep slope, showing that once a certain breakthrough was made, further development proceeded rapidly. At a 2:1 slope, jump 1 and 2 would appear at TL 9, jump 3 and 4 at TL 10, and so on. In the Imperial campaign, there is an initial flat spot immediately following introduction at TL 9 and 10, but once TL 11 is reached, jump performance increases at the 1:1 rate.

Note the other fields used in the Imperial campaign. There is contra-gravity technology appearing at TL 9. This is one of the subset approaches to the gravitics field. Contra-gravity means the negation of gravitational attraction. Another gravitic approach is thruster plate technology, in which gravitic force is transformed into directional thrust. Both these also allow the generation of artificial gravity fields aboard spaceships.

Laser focusing technology is another field included in the Imperial campaign, also appearing at TL 9. This allows laser beams to hit targets beyond a mere few thousand kilometers.

Psionics is given at the standard strength level. Some universes may not allow psionics at all, while some might use weaker or stronger variations. Note that psionics has no introduction TL, as it is not limited by technology, but only by human awareness of its existence. Because psionics is not a technology as such, and this book is specifically about technical issues, **FF&S** does not include alternative psionics rules.

Some fields are not included here, as they do not appear by TL 16, which is the current limit of the **Traveller: The New Era** Imperial campaign. Whether such fields as FTL (faster-than-light) communications or matter teleportation become available after TL 16 or are altogether impossible in this universe cannot be known to characters in the universe, as everything is impossible until the first time it is done.

The Representative Fields and Effects table shows certain representative fields and their general effects. All universes should have at least a stardrive and a defined TL for the beginning of genetic manipulation techniques. All of the other fields are optional, although most campaigns will have a gravitics approach and some form of psionics.

Some of these fields are linked to each other. For example, if using the psionic shifting approach to stardrive technology, not only would the psionic shifting capability have to be assigned to the tech level at which it becomes available, the universe would also require psionic abilities to use with the drives.

Referees who plan to create their own technological backgrounds should see Appendix II for more details.

Note on Use

The following sections are organized into three books: Major Systems, Subsystems, and Weaponry. Each of these books is further subdivided into specific chapters.

Major systems include spacecraft and vehicles, and subsystems are things like power plants, electronics, controls, etc., that are installed in the major systems. Weaponry includes those weapons installed aboard major subsystems, as well as those used on their own.

Both Book 1 and Book 3 will require the use of the subsystems book to complete their design. For this reason, **FF&S** is thumb-indexed to allow easy access to the chapters of Book 2. When a reference to a "section" of Book 2 appears in Books 1 and 3, place your thumb on the corresponding number in the column on the page's outer margin. By flipping through the book until the number appears reversed white out of a black band, you can move directly to the required section.

Representative Fields and Effects

Representative Fields	*Effects*
Stardrive	Several styles of approach (jump drive, star gates, etc.)
Gravitics	Several styles of approach (antigrav, thruster plates, etc.)
Psionics	Levels of approach (weak, standard, powerful, etc.)
Laser focusing	Yes or no, plus initial TL and slope
Matter teleportation	Yes or no, plus initial TL and slope
FTL communications	Yes or no, with styles of approach, TL, and slope

Book 1: Major Systems

CHAPTER 1
Designing Spacecraft

Traveller, as the name indicates, is a game about travel between the stars. This focus makes starships central to the game, and so players and referees will want to take a hand at designing ships of their own. It is natural, then, to begin this book with the spacecraft design sequence.

Designing ships serves two functions. First, even if the players never own or use any of the ships designed, the designs can add diversity to the sorts of ships they will encounter. Second, working a design through from hull structure to final additions to the command bridge will give players a much deeper understanding of what starships are like and how they work in the **Traveller** universe.

Before starting the design, there are several items which need to be determined. What is the tech level of the ship? What is its mission? Are there any limits on its price?

Once these decisions are made, take a sheet of paper and divide the right two-thirds of it into five columns, and label them Volume, Mass, Power, Surface Area, and Price. This will be your worksheet as you do your design (pre-made worksheets of this type are available in **Traveller Players' Forms**). Whenever a component uses volume, mass, power, or hull surface area, write the amount in the correct column. Whenever a component contributes volume, surface area, or power (hulls contribute volume and surface area, power plants contribute power) write the amount in the correct column but indicate it with a plus sign or by enclosing it in brackets. This worksheet will make designing your vessel much easier.

1. HULLS

The first step in designing a space craft is to determine the size, shape, and special configuration of the hull. All other components will then be placed inside the hull or on its surface.

First select a basic hull size from the Hull Size table (page 11). All hulls have a rate (or "tonnage") which is the displacement of the hull in tonnes of liquid hydrogen (the most common starship fuel). Therefore, a ship with a rate of 7 could hold 7 tonnes of liquid hydrogen (provided nothing else was put in the hull). Thus, **Traveller** uses the term "ton" as a unit of volume where 1 ton equals 14 cubic meters (m^3) of internal volume (also measured as 14 kiloliters). The Hull Size table indicates the volume (in cubic meters), the material volume of the shell (assuming a uniform thickness of 1 centimeter) in cubic meters of hull material, and the length of the hull (actually its diameter, as all hull ratings are based on the characteristics of a sphere) in meters.

Next, decide on the hull's form and configuration. Hull form is the basic geometric shape of the hull. As indicated above, the base values for hulls assume a spherical shape. As all hulls of the same rate have the same interior volume, hulls in less space-efficient shapes than spheres will have more surface area, greater length, and require more hull material to achieve an equivalent volume. The Hull Form and Configuration table (page 12) indicates the various hull forms available and the effects on length and material volume.

Once the basic shape is determined, the designer specifies whether the hull has an unstreamlined, streamlined, or an airframe configuration. This decision will affect the cost of the hull (streamlined and airframe configurations are more expensive). In general, airframe hulls may enter any planetary atmosphere to land on the surface or skim fuel; streamlined hulls may skim gas giants but may not land on planetary surfaces with atmospheres of greater than Thin; and unstreamlined hulls may do neither. These capabilities may be modified if the vessel is equipped with some form of weight compensating drive, such as contra-grav—see the Sublight (Maneuver) Drives chapter (Section 9).

Once the basic size and shape is determined, the hull itself is constructed. Hulls consist of hull plating and internal structure.

Hull plating may be thinner or thicker than 1 cm, but all hulls must have an armor value of at least 1. Interplanetary and interstellar vessels must have a minimum hull armor value of 10 per G rating of the maneuver drive (to protect against micro-meteors). To determine the armor value of the hull plating, decide on a thickness (in centimeters) and multiply the thickness by the toughness of the material used to construct the hull (round to the nearest whole number).

The Vehicle and Craft Construction Materials table (page 38) lists a variety of materials available at different tech levels, along with their toughness, mass per cubic meter, and their price per cubic meter. Once the designer has decided on a thickness, multiply the hull's material volume value by the hull thickness (in centimeters) to determine how many cubic meters of material is used for hull plating. Multiply this by the correct values on the Vehicle and Craft Construction Materials table (as modified by hull form and configuration) to determine mass and price.

Interior structure is also a function of the craft's acceleration and its hull material value. Multiply the hull material value from the Hull Size table (as modified by hull form, but not by configuration) by the craft's maximum acceleration in Gs, and divide the result by the hull material toughness value. The result is the volume of internal structure material used; use the Vehicle and Craft Construction Materials table to determine price and mass. The following equations recapitulate these procedures:

Hull Plating

Minimum Hull Thickness = (Gmax×10) ÷ Toughness of hull material from Vehicle and Craft Construction Materials table

Hull Plating Volume (Unstreamlined or Streamlined configuration): HPV = MV×MVM×Ht

Hull Plating Volume (Airframe configuration): HPV= MV×MVM×1.3×Ht

Hull Plating Mass (in tonnes) = HPV×Mass value of hull material from Vehicle and Craft Construction Materials table

Hull Plating Cost (in MCr) = HPV×Sm×Price of hull material from Vehicle and Craft Construction Materials table

Interior Structure

Internal Structure Volume: ISV = (MV×MVM×Gmax) + Toughness from Vehicle and Craft Construction Materials table

Internal Structure Mass: ISV×Mass value of hull material from Vehicle and Craft Construction Materials table

Internal Structure Price: ISV×Price of hull material from Vehicle and Craft Construction Materials table

Gmax: Maximum rated performance in Gs

HPV: Hull plating volume, in cubic meters

Ht: Hull thickness in centimeters, chosen by designer, but at least equal to minimum hull thickness

ISV: Internal structure volume, in cubic meters

MV: Material volume from Hull Size table, in cubic meters

MVM: Material volume multiplier from Hull Form and Configuration table

Sm: Streamlining price modifier according to selected streamlining configuration

Note also that the hull form will affect the surface area of the hull. Note at this time how much surface area is available. Surface area is used for the attachment of weapons, sensors, communicators, launch ports, etc. Keep a running record of how much surface area is used as the ship is designed.

Hull Size

Rate	*Vol*	*MV*	*L*
1	14	0.4	3.2
2	28	0.5	4
3	42	0.7	4.6
4	56	0.9	5.2
5	70	1.1	5.6
6	84	1.3	5.8
7	98	1.4	6.2
8	112	1.6	6.6
9	126	1.8	6.8
10	140	1.9	7
15	210	2.1	7.5
20	280	2.3	8.0

Rate: The hull rating is a standard measure of the volume of the hull expressed in tonnes of liquid hydrogen. Each tonne of liquid hydrogen displaces 14 cubic meters of volume (and is referred to as a "displacement ton").

Vol: The enclosed volume of the hull in cubic meters (m^3). Each cubic meter contains 1000 liters of volume, and so the term kiloliter is sometimes used interchangeably with cubic meter.

MV: Material volume, the volume (in cubic meters) of material required to enclose the hull in a shell 1 centimeter thick.

L: The length of the hull in meters. For spherical hulls, this is also the diameter.

Surface Area: Surface area in square meters is the hull material volume multiplied by 100.

Price: The price of a hull in credits is its material volume multiplied by the price shown on the Vehicle and Craft Construction Materials table.

Configuration: Hulls may be in any of several configurations. The values on the Hull Size table are for a spherical hull. With a different configuration, modify the hull material and price as shown on the Hull Form and Configuration table.

Hull Form and Configuration

Hull Form	MVM	Streamlining Price Modifier: Unstrm	Stream	Airframe	LM
Open Frame	2*	0.3	N/A	N/A	3.5
Needle	1.3	0.7	0.8	1.2**	3
Wedge	1.5	0.5	0.7	1.5**	2.5
Cylinder	1.1	0.6	0.8	2**	2
Box	1.2	0.4	0.6	N/A	1.25
Sphere	1	0.8	1	N/A	1
Dome/Disc	1.2	1.4	1.6	1.2**	1.5
Close Structure	1.4	0.3	N/A	N/A	1.75
Slab	1.5	0.5	0.7	1.5**	2.75

* Modifies hull material volume only. Surface area remains unchanged.

** Airframe configuration increases hull shell material volume (and surface area), but not internal structure. Modify hull shell material volume ×1.3 for airframe configuration hulls.

MVM: Material volume multiplier. Multiply the material volume (MV) from the Hull Size table to get the volume of 1 cm-thick hull plating for a hull of the corresponding mass and configuration.

Perform the same calculation to get the volume of that hull's internal structure stressed to 1G.

LM: Length Multiplier. Multiply the length L obtained from the Hull Size table by LM to get the length of the hull for a particular hull form.

N/A: Not available; that configuration of hull may not be built with that streamlining option.

Target Size

Once the hull size has been selected, determine its target size based on the following table.

Tons	Size
less than 1	Sub-Micro (SM)
1+	Micro (Mc)
10+	Very Small (VS)
100+	Small (S)
1000+	Medium (M)
10,000+	Large (L)
100,000+	Very Large (VL)
1,000,000+	Gigantic (G)

STEP 2. FASTER-THAN-LIGHT DRIVE

If a vessel is intended to serve as a starship (i.e., travel between stars), it will need an FTL drive. In the Imperial Space setting of **Traveller**, this will be a jump drive, but other types of drives are available in different science-fiction settings. Faster-than-light drives are covered in detail in the chapter of that name (Section 3).

STEP 3. CONTROL SYSTEMS

Control systems fall into three categories: the actual spacecraft controls, computers, and navigational aids. These are covered in detail in the Control Systems chapter (Section 4).

STEP 4. ELECTRONICS

Electronics fall into four categories: communicators, sensors, electronic countermeasures (ECM), and electronic counter-countermeasures (ECCM).

Players should be familiar with the **Traveller** space combat rules for how communicators, sensors, ECM, and ECCM systems work in order to decide which of these systems to install. All of these systems are covered in the Electronics chapter (Section 5).

STEP 5. WEAPONRY

Ships may be equipped with beam weapons, missiles, defensive screens, and the fire control systems that enable them to function effectively. All of these are covered in the Weaponry book (page 91) except for defensive screens, which are covered in the Defenses chapter (Section 6).

Sockets

If desired, a designer may install turret and/or barbette hardpoint sockets while the ship is being built. This allows easy installation of a standard turret or barbette weapon. Turret hardpoint sockets consume 3 displacement tons (42 cubic meters) while barbette hardpoint sockets consume 6 displacement tons (84 cubic meters). Both cost MCr.005 if installed during construction and, as they are empty, have negligible mass.

See Appendix 1 (page 153) for a selection of standard modular 3-ton (42 kiloliter) turrets, 6-ton (84 kiloliter) barbettes, and larger bays which can be installed on starships. Each turret and barbette is designed to fit into a standard turret hardpoint socket or barbette hardpoint socket. The turret or barbette does not add to the displacement of the ship (as the socket itself takes up the full displacement of the mount), but does add weight as shown on the chart. Sockets may be included in a design even if no weapons are installed until later.

Turret Hardpoint Socket

Displacement: 3 tons
Price: MCr0.005

Barbette Hardpoint Socket

Displacement: 6 tons
Price: MCr0.005

Type	Displacement	Volume	Diameter	Height	Surface Area
Turret	3 tons	42 m^3	3.6 m	4.2 m	10m^2
Barbette	6 tons	84 m^3	4.5 m	5.25 m	16m^2

Bays are built in 50-ton and 100-ton versions. There are no standard sockets for bays, and they are instead custom-installed when the ship is built.

OPTIONAL FEATURES

A variety of optional features are possible, such as fuel scoops, laboratories, machine shops, vehicle launch facilities, etc. Consult the Optional Features chapter (Section 7) for a complete discussion.

STEP 7. POWER SUPPLY

The ship needs a power plant to provide electric energy to various subsystems as well as to power the maneuver drive (assuming one is installed). A variety of power plants are available and are detailed in the Power Production chapter (Section 8).

STEP 8. SUBLIGHT DRIVE

The ship's power plant as installed provides electrical power to run the ship's basic systems. The power plant can be (and almost always is) also modified to provide thrust by the addition of a combustion chamber, or to power a more exotic maneuver drive. The variety of maneuver drives available are detailed in the Sublight (Maneuver) Drives chapter (Section 9).

Also included under this heading is the addition of lifter technology as required for movement on or near a planet. This is particularly the case for spacecraft in the Imperial Space campaign, which use contra-grav lifters. See the Lifters chapter (Section 10).

STEP 9. CREW AND LIFE SUPPORT

Determine the crew requirements of the ship and then fit life support to accommodate them. A variety of options for life support are covered in the Life Support chapter (Section 11).

Crew Requirements

Engineering: Ce=(P×Cp)+30
- **Ce** = Engineering crew
- **P** = Power plant peak output in megawatts
- **Cp** = Computer control multiplier

Electronics: Cl = (C+S)×Cp
- **Cl** = Electronics crew
- **C** = Number of installed communicators
- **S** = Number of installed sensors
- **Cp** = Computer control multiplier

Maneuvering: Cm=D
- **Cm** = Maneuvering crew
- **D** = Number of installed drives (maneuver drive = 1, jump drive = 1, maneuver and jump drive = 2)

Gunnery: Cg = FD+Wm
- **Cg** = Gunnery crew
- **FD** = Number of master fire directors
- **Wm** = Sum of the installed weapon mounts which are to be manned in action, times the number of crew each

Maintenance Crew: Cr = Mp+50
- **Ct** = Maintenance crew
- **Mp** = Maintenance points
  = (Jm+Em+Wm+Pm+Mm+Sm)×(0.1×Cp)
- **Jm** = Mass of installed jump drive, in tonnes
- **Em** = Mass of all installed electronics, in tonnes
- **Wm** = Mass of all installed weapons systems, in tonnes
- **Pm** = Mass of all installed power plants, in tonnes
- **Mm** = Mass of heat exchanger/ignition chamber, in tonnes
- **Sm** = Mass of all carried spacecraft, in tonnes
- **Cp** = Computer control multiplier

Ships Troops: Ct as desired.
- **Ct** = Ship's troops

Flight Crew: Cf = Q×R
- **Cf** = Flight crew
- **Q** = Total number of carried craft
- **R** = Crew required of each craft

Command: Cc = Z÷6
- **Cc** = Command crew
- **Z** = Ce+Cl+Cm+Cg+Cr+Ct+Cf

Stewards: Cs = [(Cc+Ph)÷8] + {[(Z+Pm)÷50]×Cp}
- **Cs** = Stewards
- **Cc** = Command crew
- **Ph** = High Passengers
- **Z** = Ce+Cl+Cm+Cg+Cr+Ct+Cf
- **Pm** = Middle Passengers
- **Cp** = Computer control multiplier

Medical: Cd = [(Z+Cc+Cs+Ph+Pm)÷120] + (Pl÷20)
- **Cd** = Medical crew
- **Z** = Ce+Cl+Cm+Cg+Cr+Ct+Cf
- **Cc** = Command crew
- **Ph** = High Passengers
- **Pm** = Middle Passengers
- **Pl** = Low Passengers

Note: Retain fractions during multiple-step calculations; round all fractions in the final result down.

STEP 10. WORKSTATIONS AND BRIDGE

Workstations

Certain crewmembers require the installation of workstations at which they perform their duties of controlling or monitoring certain equipment. One standard workstation (7 m³, see the Controls chapter, Section 4) must be installed for each engineering, electronics, maneuvering, master fire director, and command crewmember as calculated in the Life Support step above. Workstations for weapons are included in the weapons themselves, and need not be allocated again.

If a ship requires a bridge (see section immediately below), the workstations for the electronics, maneuvering, master fire director, and command crewmembers are installed according to those guidelines, and do not need additional normal workstations. Each engineering crewmember requires one normal workstation, regardless of whether the ship requires a bridge or not.

Even if a ship does not require the specific fitting of bridge workstations as discussed below, the workstations for electronics, maneuvering, master fire director, and command crewmembers are still considered to be grouped together into an area called the "flight deck." This flight deck is treated as a bridge, and its crew as bridge crew for purposes of hits and damage in combat.

Bridge

The ship's bridge is a compartment in the vessel containing crew workstations for command, maneuvering, sensor, communications, and fire direction personnel. It is the ship's nerve center, particularly during combat. The basic parameters of the bridge are laid down at this time, but its dimensions are not finalized until all electronics and fire control equipment is installed.

The bridge consists of a number of 1-dispacement-ton (14 cubic meters) workstations. The larger size of the workstations is to allow room for easy movement and communication by command and replacement personnel as well as to allow inspections and conferences on the bridge itself without interfering with the crew's duties.

One workstation is required per electronics, maneuvering, and command crewmember, as determined in the Life Support step, as well as one workstation per master fire director. Each bridge workstation uses 14 cubic meters of volume, masses 0.2 tonnes total, and costs an amount as shown on the Workstations table found in the Controls chapter (Section 4)

Not all ships are large or complex enough to require a bridge. A ship requires a bridge if, during the Crew Requirements step (page 13), it is discovered that *two or more* command crew are required. If a ship is of sufficient size/complexity to require a bridge and does not have one installed (i.e., has only a flight deck installed instead), the following penalties apply:

- All sensor tasks are one level more difficult
- No sensor hand-offs are allowed
- Jamming tasks are one level more difficult
- Fire tasks for turrets under local control are one level harder
- MFD-directed fire tasks are one level harder on each turn that the battery composition is changed
- Jump tasks are one level more difficult

Auxiliary Bridge: A designer may wish to install one or more auxiliary bridges with as many or fewer bridge workstations as are installed on the operating bridge (auxiliary flight decks may be installed as well, using normal workstations). Fewer workstations will limit the number of fire directors, sensors, or communicators which can be operated from the site, calculated using the normal crew formulae. If an auxiliary bridge is constructed, additional crewmembers must be carried to man it.

Flag Bridge: If the vessel is to serve as the flagship of a group of ships, it should have a flag bridge. The flag bridge is the facility from which the flag officer commanding (admiral) exercises command and control. The bridge should have bridge workstations for the same number of sensor and communication crew as does the ship's command bridge, plus bridge workstations for additional command crew, depending upon the size of the force being commanded (3+0.25×[Number of ships in the fleet]). Ships which carry large numbers of small craft may have a fighter control bridge containing 3+0.06×(Number of fighters carried) bridge workstations. These bridges allow the application of Fleet Tactics skill to multi-vessel operations. Volume, weight, and price are calculated in the same way as for the ship's bridge.

Fire Control Bridge: On particularly large ships, the designer may wish to designate a number of MFDs that are not located on the main bridge, but are grouped together separately as their own bridge. This decreases the chance of fire control capabilities being lost from hits on the operating bridge.

DESIGN EVALUATION

Once the design is complete, you will need to evaluate it to determine its game ratings.

1. Check Step

Go back and add up the volume, price, surface area, and mass of all the components. This is your chance to check to make sure that its internal occupied volume and area of surface fixtures are within what is allowed by the size of its hull. This step also provides you with a total price and mass.

Calculate two masses, loaded and empty. Loaded includes a full load of fuel, full load of cargo (assume 1 tonne per m³), and all carried craft and vehicles on board. Empty is emptied of all jump fuel and reaction mass, all cargo, and all carried craft and vehicles.

2. Record Design Features

Most of the evaluation of your design will consist of recording the features already determined by the design, such as hull form, configuration, armor value, acceleration, jump number, computer type, installed electronics, etc.

If the ship is equipped with drop tanks, it is necessary to record its displacement and determine its G-rating and jump range both with and without the tanks (this can be complicated by the fact that sometimes the higher jump performance possible with the lower displacement cannot be achieved with the fuel remaining). By the same token, a ship which carries other vessels by means of external grapples may need to calculate its jump and maneuver performance separately for when the vehicle(s) are attached and detached. In most cases these figures will be the same, as the vessel is equipped with drives large enough to operate with the small craft attached, and the craft is a small enough percentage of the mother ship that jump and maneuver do not increase appreciably when the craft is detached.

3. Allocate Damage Areas

Divide the volume (cubic meters) of the ship's components into the following categories:

Electronics: All sensors, communicators, ECM, ECCM, control systems, workstations, flight deck/bridge spaces, fire directors, and internal screens (i.e., those not mounted in bays, barbettes, or turrets).

Hold: All fuel, cargo space, hangars, labs, and shops.

Quarters: All life support systems (including the installed artificial gravity/G-compensators), hull material volume, accommodations, sick bays, and low berths.

Engineering: All power plant, FTL drives, sublight (maneuver) drives (including CG lifters), and fuel-processing equipment.

Weapons Mounts: Each individual weapons mount, including bay-, barbette-, or turret-mounted defensive screens.

Now take the total displacement of the ship and divide by 20. The result is the number of cubic meters of volume available in each of the 20 hit location areas. Allocate the above damage areas to distinct hit locations in proportion to how much of the volume of the ship they consume. Use the ships already rated as a guide.

In general, the bridge (i.e., the largest concentration of electronics) should be in the nose of the vessel to minimize the amount of circuitry between the bridge and the sensor arrays, which are usually mounted forward as well. If the ship has a maneuver thruster, the majority of the engineering space should be aft, but any ship with CG lifters can have engineering space forward on its ventral side as well. If you have a visual image of what the ship looks like, try to make the hit locations correspond with that as much as possible. When allocating the volume of a spinal mount to hit locations, divide it evenly among all 20 hit locations.

4. Place Surface Fixtures

Surface fixtures include all antennae, radiators, external grapples, and hatches. Surface area devoted to slower-than-light maneuver drive (aft), jump drive (aft), and lifters (ventral surfaces) should also be allocated. These systems do not have surface hit locations listed on the ship's damage table (these have their damage handled by internal damage in the same hit locations), but are allocated in this step to ensure that other systems are not improperly placed where these engineering systems should be. Divide the total hull surface area by 20 to determine the surface area of each hit location and allocate surface fixtures accordingly.

5. Evaluate System Damage

Record the tonnage of each major system in the vessel (each entry on the Damage Type chart, plus each separate weapons mount, plus each antenna on the hull surface) and determine its damage capacity. Systems can take 1 minor hit per 5 metric tonnes of mass (to a maximum of 4), or 1 major hit per 100 metric tonnes of mass (21 or more metric tonnes rounds up to 1 major hit; above multiples of 100 tonnes, 20 tonnes or less round down, 21+ round up). Note that small components (such as laser communicators or active EMS antennae) always take 1 minor hit, even if they have no listed mass or a total mass much smaller than 5 tonnes.

The following specific systems should always be evaluated:

Electronics

Each sensor and its antenna, based on mass.

Each communicator and its antenna, based on mass.

Each master fire director and its antenna, based on its mass.

Each ECM system and its antenna, based on its mass. EMM is a special case. The EMM controller has its hits based on its total mass, using normal procedures. For the radiators, allow 1 minor hit for each MW of power allocated to the EMM system. Note that this is an exception to the rule that systems may only have a maximum of 4 minor hits.

Hold

Hangar: The total mass of the hangar spaces divided by 20 equals the number of major hits (round to the nearest whole number).

Labs: Based on the total mass of each lab.

Shops: Based on the total mass of each shop.

Cargo Space (CS): The total mass of the cargo carried is a measure of how much damage is absorbed when the cargo is hit by a weapon. This varies with cargo type. If cargo space is empty, cargo space hits are re-rolled as excess damage.

Quarters

Stateroom (SR): Each large stateroom takes 1 major hit. Each small stateroom takes 2 minor hits.

Life Support: This value is based on the mass of all life support machinery (not including G-compensators) plus the total hull material mass (hull shell and internal structure). Two-thirds of the total mass is used to determine the damage level of the main life support system (LS), and the remaining third determines the damage of the emergency life support (ELS) system.

Artificial Gravity (AG): Based on the total volume of the vessel's G-compensators.

Low Berth (LBth): The low berths take 1 minor hit per low berth.

Engineering

When using alternate technology fields for FTL and/or sublight drives, the names and number of these systems will change. For example, a ship with stutterwarp uses this for FTL and sublight drive, while a ship with thruster plates uses these for sublight drive and lifters. The systems listed below are for the Imperial Space campaign, which uses three systems (JD, MD, CG). Designers using other systems must make adjustments accordingly.

Jump Drive (JD): Based on the mass of the jump drive itself.

Power Plant (PP): Based on the mass of the power plant.

Maneuver Drive (MD): Based on the mass of the heat exchanger/ignition chamber for the maneuver drive.

Contra-Grav Lifters (CG): The mass of the CG lifters.

Fuel-Processing Plant (FPP): Based on the total mass of the plant.

Weapons Mounts

Each individual weapons mount: These may be laser turrets (LT), barbettes (LB), or bays (LBy); missile turrets (MT), barbettes (MB), or bays (MBy); particle accelerators (PA); meson guns (MG); etc. All weapons take hits based on their total mass.

6. Determine Arcs of Fire

The arc of fire of each weapon is determined by the hull location of the weapon and the hull form of the vessel. The following table shows which hull location weapon stations can fire into which arcs on each type of hull form available.

After determining which arcs a weapon can fire into, note the information on the ship's control panel data sheet.

ARCS OF FIRE BY HULL FORM

Hull Form	(1) Bow On	(2) Bow Quarter	(3) Broadside	(4) After Quarter	(5) Stern On
Open Frame	1-20	1-20	1-20	1-20	1-20
Needle	1-15	1-19	1-20	2-20	6-20
Wedge	1-19	1-19	2-19	16-20	16-20
Cylinder	1-5	1-15	2-19	6-20	16-20
Box	1-5	1-15	2-19	6-20	16-20
Sphere	1-11	1-15	2-19	6-20	10-20
Dome/Disc	1-11	1-15	2-19	6-20	10-20
Close Structure	1-9	1-15	2-19	6-20	12-20
Slab	1-5, 10-11	1-15	2-19	6-20	10-11, 16-20

7. Determine Maintenance Points

Take the loaded mass of the vessel, but subtract the weight of any carried craft and vehicles (their maintenance points are calculated separately), then subtract the mass of its hull shell. Divide the result by the TL modifiers here.

TL	Maint Modifier
4-5	2
6-7	3
8-9	4
10-12	5
13-15	6
16-18	8
19-21	10
22+	12

If the craft has two or more computers installed (three or more computers for jump-capable ships, St or Fb only, not flight computers), one of these is considered to be a dedicated maintenance troubleshooting computer, which allows the current figure to be divided by 4. If there is only one computer (or two or less for a starship), the figure remains unreduced. This is the number of maintenance points required by the craft. (The loaded figure is used because items such as cargo and fuel do require regular attention to see that they have not shifted, leaked, etc.)

8. Atmospheric Speed

Any spacecraft which is streamlined can hurtle through the atmosphere at hypersonic speeds (and will have to in order to reach orbit), but it cannot necessarily maneuver at those speeds. The maximum atmospheric maneuver speed of a streamlined spacecraft, regardless of its G rating, is 1100 kph. The maximum atmospheric maneuver speed of an airframe spacecraft is determined by the G rating, as shown below

G	Speed (kph)
1	3500
2	4700
3	5300
4	5600
5	5800
6	5900

Maximum atmospheric maneuver speed is used to determine the difficulty modifier for hitting a flying spacecraft in an atmosphere (**Traveller**, page 294). The maximum atmospheric maneuver speed multiplied by 0.75 is the spacecraft's atmospheric cruising speed, which is used to determine travel times in the atmosphere when the spacecraft is used as an aircraft.

Spacecraft with lifters (contra-gravity, thruster plates, etc.) may fly NOE (nap-of-the-earth). Spacecraft have a safe NOE speed equal to their maximum atmospheric speed multiplied by 0.25, but never more than allowed by their installed terrain-following avionics (or 40 kph if no avionics are installed).

Combat Move: The high mode combat movement (in 10-meter grid squares per combat turn) is equal to the spacecraft's maximum atmospheric flight speed (in kilometers per hour) multiplied by 0.139. The safe NOE combat movement (in 10-meter grid squares per combat turn) is equal to the spacecraft's maximum NOE speed (in kilometers per hour) multiplied by 0.139, rounded to the nearest whole number.

Travel Move: The high mode travel movement rate (in kilometers per 4-hour period) is equal to the cruising speed (in kilometers per hour) multiplied by 4. The NOE mode travel movement rate (in kilometers per 4-hour period) is equal to the safe NOE speed (in kilometers per hour) multiplied by 6.

CHAPTER 2
Ground Vehicle Design

A ground vehicle, for purposes of these rules, is defined as any conveyance which operates in physical contact with the ground. This includes wheeled vehicles, tracked vehicles, and legged vehicles. Ground vehicles are produced by adding components to a basic structure. The vehicle's volume is determined first and specific components are then added until the volume is filled. Components have a weight and price; the vehicle's weight and price are determined by adding together the weights and prices of its components.

Before starting the design, there are several items which need to be determined. What is the tech level of the vehicle? What is its mission? Are there any limits on its price?

Once these decisions are made, take a sheet of paper and divide the right two-thirds of it into five columns, and label them Volume, Mass, Power, Surface Area, and Price. This will be your worksheet as you do your design. Whenever a component uses volume, mass, power, or chassis surface area, write the amount in the correct column. Whenever a component contributes volume, surface area, or power (hulls contribute volume and surface area, power plants contribute power) write the amount in the correct column but distinguish it with brackets or a "+" sign. This worksheet will make designing your vehicle much easier.

STEP 1. CHASSIS

The first step is to determine the size and general configuration of the chassis. Select a chassis size from the Chassis Size table below. All chassis have a rate which is the displacement of the hull in tonnes of liquid hydrogen (a common measure as it is the most common fuel). Therefore, a vehicle with a rate of 1 could hold 1 tonne of liquid hydrogen (provided nothing else was put in the chassis). Each "ton" of displacement consists of 14 cubic meters (m^3) of internal space (or 14 kl). The Chassis Size table indicates the volume (in m^3), and the material volume of the shell (assuming a uniform thickness of 1 cm) in cubic meters of material.

Note that this table is identical to that found in the starship design section of the rules, with two exceptions. First, the vehicle chassis listed are all assumed to be laid out as elongated six-sided blocks, and so have already had their material volumes modified accordingly. Second, the "hull length" column is omitted as being irrelevant to vehicle design.

Vehicles may be designed using chassis which fall between two listed values on the table by means of interpolation. Larger vehicle chassis may be used by using the spacecraft Hull Size table (page 11). Use 1.4 for the material volume multiplier (MVM) for a vehicle chassis.

CHASSIS SIZE

Rate	*Vol*	*MV*
1	14	0.6
2	28	0.7
3	42	1.0
4	56	1.3
5	70	1.5
6	84	1.8
7	98	2.0
8	112	2.2
9	126	2.5
10	140	2.7

Once the chassis size is determined, determine its configuration. There are three general vehicle configurations: standard, turret, and small turret. Most vehicles, such as cars, trucks, air rafts, etc., are standard configuration. Turret vehicles, like tanks, have a turret which holds a large gun and one or more crewmembers. Small turret vehicles have a single small turret which holds a light weapon and sometimes a gunner (although it is often remotely controlled).

A turret vehicle has considerable waste volume representing the free area around the turret to enable it to traverse and fire in all directions. At higher tech levels, advances in engineering allow larger and larger turrets on chassis of a given size, reducing this inefficiency. To represent this feature in the design, all components mounted in the turret consume more than their *actual* volume. To determine the exact increase in volume, consult the Turret Efficiency table, below.

TURRET EFFICIENCY

TL	*Volume*
4	×6
5	×5
6	×4
7	×3
8+	×2

The volume of turret components after multiplying them by these turret efficiency values is referred to as their *effective volume.*

All components in a small turret (see below, in Weaponry) have an effective volume equal to 10 times their actual volume.

Next, the chassis itself is constructed by enclosing the chassis space with hull material, called hull plating.

The Vehicle and Craft Construction Materials table (Section 1, page 38) lists a variety of materials available at different tech levels, along with their toughness, mass per cubic meter, and their price per cubic meter. Once the designer has decided on a thickness, multiply the hull's material volume value by the hull thickness (in centimeters) to determine how many cubic meters of material is used for hull plating. Multiply this by the correct values on the Vehicle and Craft Construction Materials table (as modified by hull form and configuration) to determine mass and price.

Hull plating may be thinner or thicker than 1 cm, but all chassis must have an armor value of at least 1. To determine the armor value of the hull plating, decide on a thickness (in centimeters) and multiply the thickness by the toughness of the material used to construct the hull.

Once the base armor value (that enjoyed by all surfaces) is determined, the designer may decide to put additional armor on one or more surfaces of the vehicle. This is done by adding material weight and cost to the vehicle, but it adds additional thickness (and thus protection) to that face. Each additional centimeter of material adds to the material volume as shown on the following table.

Face	*Increase per cm*
Front or rear (each)	10%
Sides (both)	15%
Top or bottom (each)	25%

For example, a vehicle built around a 3-ton hull (42 kiloliters) has a material volume of 1 (meaning each centimeter of hull thickness all the

way around the hull requires 1 cubic meter of actual hull material). The designer decided to increase the thickness of the front armor of the vehicle. For each extra centimeter of front armor, add 0.1 (10% of1) cubic meters to the total hull material.

Once all armor is installed, the designer may further increase its effectiveness by sloping it. The top and bottom may not be sloped, but the front, rear, and sides may be. Armor may be installed at a moderate slope (about 30°) or a radical slope (about 60°). A moderate slope increases the effective armor value of a face by 50%. A radical slope increases the effective armor value of a face by 100%.

Sloping armor does not add to either the weight or price of the vehicle, but does subtract from its volume. The volume cost of sloping an armored face is expressed as a multiple of the entire enclosed volume of the chassis and is noted on the table below.

Armor Slope

Face	*Moderate*	*Radical*
Front or rear	10%	20%
Sides (both)	20%	40%

For example, a vehicle with a size 6 hull (84 kiloliters) has a radical slope to its frontal armor. This uses up 20% of the original volume, or 16.8 cubic meters.

Vehicles may be designed as *open* vehicles, meaning they are open-topped and partially open-sided. These vehicles sometimes have a glass or plastic transparent windscreen or roof added later. Open vehicles multiply their hull material volume by 0.7. They have no armor against overhead attacks, and attacks from the side and rear are rolled for to determine if they strike armor or glass (using the open vehicle rule).

STEP 2. SUSPENSION

The suspension is the mechanism in contact with the ground. There are five specific suspension types: restricted wheel, wheel, cross-country wheel, track, and walker. Different suspension types are available at different tech levels. Each suspension takes up a fixed percentage of the chassis volume. The Suspension Table lists those values as well as the weight and price per cubic meter of installed suspension.

Suspension

Type	*TL*	*Vol*	*Mass*	*SA*	*Price*
Restricted Wheel	4	2.1	0.42	70	.000525
Restricted Wheel	5	1.4	0.28	70	.00035
Wheel	5	2.1	0.42	70	.000525
Cross Country Wheel	5	2.8	0.56	60	.0007
Track	5	2.8	4.2	50	.0014
Walker	8	2.8	2.8	80	.0028

TL: Tech level available.

Kl: Volume in kiloliters (cubic meters) per displacement ton (14 kl) of hull.

Mass: Mass in tonnes per displacement ton (14 kl) of hull.

SA: Useful surface area in square meters is equal to the chassis material volume (from the Chassis Size table) times this number. This computation shows the surface area left after allowing for the surface area of the suspension itself plus such standard features as hatches, vision devices, etc. Useful surface area is used for the installation of sensor and communications antennae, and other surface area consuming items.

MCr: Price in millions of credits per displacement ton (14 kl) of hull.

STEP 3. CONTROL SYSTEMS

Vehicles require only basic mechanical controls to drive, but may have more sophisticated controls if a computer is installed. These are covered in detail in the Control Systems chapter (Section 4).

STEP 4. LIFE SUPPORT

The type of life support required by a vehicle depends largely on its intended mission. A variety of options for life support are covered in the Life Support chapter (Section 11). If any extended accommodations are to be fitted (such as staterooms or bunks), they are installed at this time. Only vehicles intended for very long trips, days or weeks, are fitted with bunks or staterooms, and even then they are usually intended for use by several crewpersons in rotation.

STEP 5. ELECTRONICS

Electronics fall into four categories: communicators, sensors, electronic countermeasures (ECM), and electronic counter-countermeasures (ECCM).

Players should be familiar with the **Traveller** combat rules for how communicators, sensors, ECM, and ECCM systems work in order to decide which of these systems to install. All of these systems are covered in the Electronics chapter (section 5).

STEP 6. WEAPONRY

Vehicles may be equipped with weapons, missiles, defensive systems, and the fire control systems that enable them to function effectively. All of these are covered in the Weaponry book (beginning on page 91) except for defensive systems, which are covered in the Defenses chapter (Section 6), and fire control, which is in Section 14. A number of special considerations apply to vehicle-mounted weapons, however.

Weapon Mounts: Vehicle-mounted guns do not require carriages, tripods, or other such mounts, as the vehicle itself serves as the mount. However, the type of vehicle mount and its location must be specified. There are five main types of vehicle mounts: chassis, turret, small turret, pintel, and open. As a sixth option, tac missiles may be mounted on the outside of the vehicle on launch rails.

Weapons in chassis mounts emerge from one of the six faces of the chassis. Although fine adjustments to their bearing and elevation is possible, gross weapon pointing is achieved by repositioning the vehicle itself.

A turret is a fully rotating armored compartment set onto the top of the chassis. The advantage of a turret is that it allows fire in any direction without without requiring the vehicle to be pointing or travelling in that direction. A turret (as opposed to a small turret) is one whose effective volume is more than 10% of the total chassis volume. Indirect fire weapons must be in either turrets or open mounts (see below). Although referred to simply as "turrets" in the basic rules, these will sometimes be referred to as "main turrets" in the rules below to distinguish them from small turrets.

A small turret is usually on top of a turret, or in the case of a turretless vehicle, on top of the chassis itself, but it could be mounted on any face of the vehicle. Small turrets may have an effective volume of no more than 10% of the total vehicle volume. If a small turret is to be manned, it must allocate volume for the crewmember equal to one-half the volume of the member's crewstation. Manned small turrets are also called cupolas, unmanned small turrets are referred to as *remote mounts*. Remote mounts are controlled from crewstations within the hull. The equipment necessary to remotely control the mount (periscopes, repeaters, etc.) is subsumed within the mass and price of the remote turret and crewstation (but see Step 8, Crew, below for fire control requirements).

Both types of turret have front, side, top (or in the case of a belly turret, bottom), and rear armor equal to those values calculated for the entire vehicle.

A pintel mount is a simple post or curved rail on which is mounted a light weapon, such as a machinegun or autocannon. It is usually mounted on top of the chassis or turret.

An open weapon is a large weapon mounted in the chassis of an open-topped vehicle. Many early self-propelled artillery pieces were of this configuration. Indirect fire weapons must either be in open mounts or turrets.

Weapon Stabilization: Stabilization gear enables a vehicle to fire its weapons while moving; the Stabilization table (see the Fire Control chapter, Section 14) lists the characteristics of stabilization gear at various tech levels.

Mechanical Loading Assistance: A gun may reduce its requirement for loaders by having mechanical loading assistance for the gun. Mechanical loading assistance is covered in the actual weapon design sequences. Loading assisters have a volume of 1 cubic meter per ton and must be located with the weapons mount and the ammunition. (Note that with mechanical loading assistance, the ammunition must be stored in the same part of the vehicle as the gun mount; i.e., in the turret for a turret-mounted weapon, or in the hull for a chassis or open-mount weapon.)

Autoloader: CPR guns require one or more crew as loaders in addition to the gunner. All of the weapon's loaders may be replaced by an autoloader; weapons in remote mounts *must* have autoloaders. Autoloader characteristics are calculated during the weapon design sequence. Half of the autoloader's volume is in the part of the vehicle with the weapon mount and the rest is in the part of the vehicle where the ammunition is stored.

STEP 7. POWER PLANT

The vehicle needs a power plant to provide electric energy to various subsystems as well as to power the suspension. A variety of power plants are available and are detailed in the Power Production chapter (section 8).

Fuel: Fuel tankage for the power plant is also calculated at this time.

Auxiliary Water Propulsion: Amphibious tracked vehicles do not require auxiliary water propulsion, as their tracks act as paddles and can drive them forward slowly. Wheeled amphibious vehicles (and tracked amphibious vehicles looking for more speed than their tracks will give them) may have auxiliary water propulsion. Auxiliary water propulsion occupies volume equal to 0.05 of the power plant volume. It masses 1 tonne per cubic meter and costs MCr0.001 per cubic meter.

STEP 8. TRANSMISSION

Ground vehicles must have a transmission. The size of the transmission depends on the tech level of the vehicle and the output of the power plant.

Wheel and Tracked Transmissions

TL	*Vol/T*	*Vol/W*	*Price*
4-5	5	3	1000
6	2	1	1250
7+	.5	.3	1500

Walker Transmissions

TL	*Vol/L*	*Price*
8	8	10,000
9	2	2500
10	.4	675

TL: Tech level of availability

Vol/T: Volume (in cubic meters) of a tracked vehicle suspension per MW of power output.

Vol/W: Volume (in cubic meters) of a wheeled vehicle suspension per MW of power output.

Vol/L: Volume (in cubic meters) of a legged (walker) vehicle suspension per MW of power output.

Price: Price (in MCr) per cubic meter of installed transmission.

Mass: The mass (in tonnes) of the transmission is equal to its volume (in cubic meters)

STEP 9. CREW

Each vehicle crewmember requires a crewstation, and each passenger requires a seat.

Crewstations: Two types of crewstations are possible: cramped and open. Open vehicles may have cramped crewstations while enclosed vehicles must have open crewstations. Both types are listed in the Controls chapter (Section 4). The crewstations must be from the same tech level as the controls installed in Step 3.

Seats: Passenger seats are found in the Optional Features chapter (Section 7).

Each vehicle requires a driver. A vehicle commander is optional but recommended on enclosed armored fighting vehicles. If the vehicle has a main turret, the commander's station must be in the turret.

If one or more weapons are installed, a gunner is required, and a loader may be necessary as well. A gunner may fire more than one weapon, but he may only fire weapons controlled from his station (called a *weapon station*). One station may control all weapons mounted on the same side of the chassis or in any part of a turret. One station is required for each small turret unless it is remotely controlled. One station may control any number of remote turrets, but a gunner may never operate more than one weapon in a single turn. A weapon station must be in the same part of the vehicle as the weapons controlled, except that a turret-mounted weapon may be controlled from the chassis and remote-mounted weapons may be controlled from anywhere.

Fire Control: During the weapon design sequence, fire control systems are specified for various weapons. However, the designer should note that for vehicle-mounted weapons, fire control systems must be provided for each weapon station, not just for

each weapon. For a vehicle with only one weapon and only one gunner, this distinction is immaterial, but if that same vehicle were designed to allow the gun to be fired from two separate weapon stations, each would require a separate fire control system.

If the weapon station controlling a weapon is in a different part of the vehicle from the weapon itself, the volume of the fire control equipment is divided evenly between the two locations.

Weapon stations that only control small arms or tac missiles do not require fire control systems. However, tac missile weapon stations are equipped with tac missile control units (see page 149).

STEP 11. CARGO

All remaining volume may be allocated to ammunition stowage, cargo space, or declared waste volume. Waste volume has no effect on the design.

Ammunition stowage has no cost but adds the weight of the ammunition to the loaded weight of the vehicle.

Cargo volume has no cost but adds to the loaded weight of the vehicle. Multiply the cargo volume, in cubic meters, by 0.25 to determine the addition, in metric tonnes, to the vehicle's loaded weight.

DESIGN EVALUATION

Once the design is complete, you will need to evaluate it to determine its game ratings.

1. Check Step

Go back and add up the volume, price, surface area, and mass of all the components. This is your chance to check to make sure that its internal occupied volume and area of surface fixtures are within what is allowed by the size of its hull. This step also provides you with a total price and mass.

2. Record Design Features

Most of the evaluation of your design will consist of recording the features already determined by the design, such as armor values, weapon statistics, installed electronics, crew, passengers, etc. Note the volume of the original chassis as its transport volume (the space it takes up in the hold of a starship or transport vehicle).

At the same time, total the price of the vehicle and its empty and loaded weights. Empty weight is the vehicle without any ammunition, fuel, cargo, crew, or passengers. This is essentially the weight of the vehicle as it comes off the assembly line, and is also what it weighs when being transported by another vehicle or starship.

Loaded weight includes a full load of ammunition, full cargo (0.25 tonnes per cubic meter), and a weight allowance of 100 kilograms per passenger and crew. This is its typical weight when in operation.

Flotation: Determine enclosed volume. To do so, first add up actual turret volume, then add up the effective turret volume. Subtract the effective turret volume from the vehicle's transport volume (the volume of its nominal chassis size) and add the actual turret volume. The result is the vehicle's enclosed volume. Divide the enclosed volume by the vehicle's loaded weight in metric tonnes. If the result is greater than 1, the vehicle floats; if it is 1 or less, the vehicle will not float.

Suspension Damage Resistance: Compute suspension damage resistance (SDR): for tracked vehicles, this is the suspension's armor value; for wheeled and walker vehicles, its critical damage level (see **TNE** page 300). These are based on the vehicle's chassis size *in displacement tons* as chosen in Step 1.

Tracked SDR = 2 × chassis size, Wheeled SDR = 1 + chassis size, Walker SDR = chassis size.

3. Determine Movement

Movement of ground vehicles is based on top road speeds and cross-country speeds, both of which are determined by the vehicle's loaded power-to-weight ratio as well as its suspension. For purposes of the power-to-weight calculations, the vehicle's motive power is the total output of its power plant minus energy used to run other systems (such as life support, electronics, weapons, etc.).

Road Speed:

Base road speed in kilometers per hour = 5 + ([MW÷ LW]×2500)

MW: Vehicle motive power in megawatts

LW: Loaded weight of the vehicle in tonnes

Tracked and wheeled vehicle modifiers

Each tech level above 5	+1 kph
If wheeled	+10 kph
If light wheeled*	+15 kph
If legged	×0.25 kph

*To qualify for the light wheeled bonus, vehicle must be equal to or less than the listed weight (in tonnes) for its tech level on the following table:

LIGHT WHEELED VEHICLES

TL	*Weight*
5	5–
6	10–
7	15–
8	20–
9	25–
10	30–
11	35–
12	40–

TL: Tech level at which vehicle appears.

Weight: Maximum weight of a light vehicle at that tech level.

Cross-Country Speed:

Legged vehicles have the same speed cross-country as they have on a road.

Wheeled vehicle cross-country speed depends on the type of suspension used.

Type	*Cross-Country*
Restricted Wheel	0.1
Wheel	0.2
Cross-Country Wheel	0.4

Type: Suspension type installed on vehicle.

Cross-Country: Cross-country speed in kph equals road speed times this multiplier.

Tracked vehicle cross-country mobility depends on the power-to-weight ratio of the vehicle.

P/W	*T*
.001-.0039	0.4
.004-.0079	0.5
.008-.0119	0.6
.012-.0159	0.7
.016+	0.8

P/W: Power-to-weight ratio. Divide vehicle's motive power in megawatts by its loaded weight in tonnes. Use the line that corresponds to the result.

T: Tracked multiplier. Cross-country speed in kph equals road speed times this multiplier.

Water Speed: Tracked vehicles without auxiliary water propulsion and wheeled vehicles with auxiliary water propulsion have a water speed equal to their road speed multiplied by 0.1. Tracked vehicles with auxiliary water propulsion have a water speed equal to their road speed multiplied by 0.2.

Combat Move: The safe combat movement (in meters per turn) is the vehicle's maximum speed, in kilometers per hour, multiplied by 0.463, rounding the result to the nearest increment of 5. This calculation is made separately for road, off-road, and water movement based on the maximum road, off-road, and water speeds.

Travel Move: The vehicle's travel movement rate (in kilometers per 4-hour period) is equal to its safe combat move (in meters per turn) multiplied by 4.32, rounded to the nearest increment of 5.

4. Firing Characteristics

Records the firing characteristics of each mounted weapon as well as the effects of installed stabilization and fire control.

5. Determine Maintenance Points

Divide the loaded mass of the vehicle by the maintenance modifier appropriate to tech level as shown below.

TL	*Maintenance Modifier*
4-5	2
6-7	3
8-9	4
10-12	5
13-15	6
16+	8

Any ground vehicle which has two full-size computers (model St or Fb) installed should divide this result by 4 to get final maintenance points.

CHAPTER 3
Lift Vehicle Design

A lift vehicle is a transition between ground vehicles and aircraft, and has some of the characteristics of each. Lift vehicles are those which are, literally, lifted or levitated off the ground by some means other than wings. In the basic design rules there are two means of lifting a vehicle: contra-gravity and air cushion.

Lift vehicles are produced by adding components to a basic structure. The vehicle's volume is determined first, and specific components are then added until the volume is filled. Components have a mass and price; the vehicle's mass and price are determined by adding together the masses and prices of its components.

Before starting the design, there are several items which need to be determined. What is the tech level of the grav vehicle? What is its mission? Are there any limits on its price?

Once these decisions are made, take a sheet of paper and divide the right two-thirds of it into five columns, and label them Volume, Mass, Power, Surface Area, and Price. This will be your worksheet as you do your design. Whenever a component uses volume, mass, power, or chassis surface area, write the amount in the correct column. Whenever a component contributes volume, surface area, or power (chassis contribute volume and surface area, power plants contribute power) write the amount in the correct column, but distinguish it with brackets or a "+" sign. This worksheet will make designing your vehicle much easier.

STEP 1. CHASSIS

The first step is to determine the size and general configuration of the chassis. Select a chassis size from the Chassis Size table below. All chassis have a rate which is the displacement of the hull in tonnes of liquid hydrogen (a common measure as it is the most common fuel). Therefore, a vehicle with a rate of 1 could hold 1 tonne of liquid hydrogen (provided nothing else was put in the chassis). Each "ton" of displacement consists of 14 cubic meters (m^3) of internal space (or 14 kiloliters). The Chassis Size table indicates the volume (in cubic meters), and the material volume of the shell (assuming a uniform thickness of 1 centimeter) in cubic meters of material.

Note that this table is identical to that found in the starship design section of the rules, with two exceptions. First, the vehicle chassis listed are all assumed to be laid out as elongated six-sided blocks, and so have already had their material volumes modified accordingly. Second, the "hull length" column is omitted as being irrelevant to vehicle design.

Lift vehicles may be designed using chassis which fall between two listed values on the table by means of interpolation. Larger vehicle chassis may be used by using the spacecraft Hull Size table on page 11. Use 1.4 for the material volume multiplier (MVM) for a vehicle chassis.

Chassis Size

Rate	*Vol*	*MV*
1	14	0.6
2	28	0.7
3	42	1.0
4	56	1.3
5	70	1.5
6	84	1.8
7	98	2.0
8	112	2.2
9	126	2.5
10	140	2.7

Once the chassis size is determined, determine its configuration. There are five general chassis configurations: Simple, Fast Subsonic, Transonic, Supersonic, and Hypersonic. Each of these represents progressively more streamlined chassis which can reach higher and higher speeds. Air cushion vehicles may only use simple chassis; grav vehicles may use any chassis shown.

Each chassis size has a volume cost, which is the waste volume consumed by streamlining, as well as a variety of other values used in later calculations.

Lift Vehicle Chassis Configurations

Type	*Vol*	*SA*	*Price*	*Max*	*Eff*
Simple	0.00	70	1.00	400	0.85
Fast Subsonic	0.05	70	1.02	800	0.90
Transonic	0.10	65	1.03	1200	0.95
Supersonic	0.20	60	1.04	2800	1.00
Hypersonic	0.30	55	1.1	5000	1.00

Vol: Waste volume consumed by streamlining is equal to the total volume of the chassis multiplied by this value.

SA: Useful surface area in square meters is equal to the chassis material volume (from the Chassis Size table) times this number. This computation shows the surface area left after allowing for standard features such as hatches, vision devices, intakes, exhausts, lifter plates, landing skids, etc. Useful surface is used for the installation of sensor and communications antennae, and other surface area consuming items.

Price: The price of the hull plating is its normal material cost times the value shown on the chart.

Max: The maximum atmospheric speed of the chassis in kilometers per hour.

Eff: The efficiency of the chassis, used to calculate maximum speed.

Once the chassis configuration is chosen, the chassis itself is constructed by enclosing the chassis space with hull material, called hull plating.

The Vehicle and Craft Construction Materials table (Section 1, page 38) lists a variety of materials available at different tech levels, along with their toughness, mass per cubic meter, and their price per cubic meter. Once the designer has decided on a thickness, multiply the hull's material volume value by the hull

thickness (in centimeters) to determine how many cubic meters of material is used for hull plating. Multiply this by the correct mass value on the Vehicle and Craft Construction Materials table to determine mass. Price in millions of credits is determined by multiplying material volume by hull thickness in centimeters, the correct price multiplier from the Vehicle and Craft Construction Materials table, and the price modifier from the Lift Vehicle Chassis Configuration table.

Hull plating may be thinner or thicker than 1 centimeter, but all chassis must have an armor value of at least 1. To determine the armor value of the hull plating, decide on a thickness (in centimeters) and multiply the thickness by the toughness of the material used to construct the hull.

Once the base armor value (that enjoyed by all surfaces) is determined, the designer may decide to put additional armor on one or more surfaces of the vehicle. This is done by adding material weight and cost to the vehicle, but it adds additional thickness (and thus protection) to that face. Each additional centimeter of material adds to the material volume as shown on the following table.

Face	*Increase per cm*
Front or rear (each)	10%
Sides (both)	15%
Top or bottom (each)	25%

For example, a vehicle built around a 3-ton hull (42 kiloliters) has a material volume of 1 (meaning each centimeter of hull thickness all the way around the hull requires 1 cubic meter of actual hull material). The designer decided to increase the thickness of the front armor of the vehicle. For each extra centimeter of front armor, add 0.1 (10% of 1) cubic meters to the total hull material.

Once all armor is installed, the designer may further increase its effectiveness by sloping it. The top and bottom may not be sloped, but the front, rear, and sides may be. Armor may be installed at a moderate slope (about 30°) or a radical slope (about 60°). A moderate slope increases the effective armor value of a face by 50%. A radical slope increases the effective armor value of a face by 100%.

Sloping armor does not add to either the weight or price of the vehicle, but does subtract from its volume. The volume cost of sloping an armored face is expressed as a multiple of the entire enclosed volume of the chassis and is noted on the table below:

ARMOR SLOPE

Face	*Moderate*	*Radical*
Front or Rear	10%	20%
Sides (both)	20%	40%

For example, a vehicle with a size 6 hull (84 kiloliters) has a radical slope to its frontal armor. This uses up 20% of the original volume, or 16.8 cubic meters.

Simple chassis must have at least a moderate frontal slope. Fast subsonic chassis must have a radical frontal slope.

Vehicles may be designed as *open* vehicles, meaning that they are open-topped and partially open-sided. These vehicles sometimes have a glass or plastic transparent windscreen or roof added later. Open vehicles multiply their hull material volume by 0.7. They have no armor against overhead attacks and attacks from the side and rear are diced for to determine if they strike armor or glass (using the open vehicle rule).

Turrets: Any vehicle may be built as a turreted vehicle. A turreted vehicle has a large main turret mounting a powerful weapon. There is considerable waste volume representing the free area around the turret to enable it to traverse and fire in all directions. All components mounted in a large main turret consume more than their *actual* volume. To determine the exact increase in volume, consult the Turret Efficiency table, below.

TURRET EFFICIENCY

TL	*Volume*
6	×4
7	×3
8+	×2

The volume of turret components after multiplying them by these turret efficiency values is referred to as their *effective volume*.

All components in a small turret (see below, in Weaponry) have an effective volume equal to 10 times their actual volume.

In addition, turreted vehicles are less aerodynamic than non-turreted vehicles. For each 1% of the total chassis volume (after reductions for hull slope) that is devoted to *effective* turret volume, the maximum speed of the chassis will be reduced by 1% (see page 26, "Determine Movement").

Main turrets (see Step 6, Weaponry, below) must be locked in the forward position during high-speed flight or the vehicle will become unstable and risk crashing. The maximum safe speed of any lift vehicle while slewing its turret is 300 kilometers per hour. (Lift vehicles may fly at higher speeds while slewing their turrets, but the drivers must make skill rolls to avoid a mishap according to the normal overdriving rules.) Small and airborne type turrets (see Step 6, Weaponry, below) have no such penalty.

STEP 2. SUSPENSION

The suspension is the mechanism in contact with the ground. There are four specific suspension types: air cushion, standard contra-grav, improved contra-grav, and high-effeciency contra-grav. Different suspension types are available at different tech levels. Each suspension takes up a fixed percentage of the chassis volume. The suspension table lists those values as well as the weight and price per cubic meter of installed suspension.

Contra-grav negates the gravitational force of over 99% of the vehicle's weight. This allows light lift vehicles to actually be buoyant on worlds with sufficiently dense atmospheres. However, all contra-grav vehicles are assumed to have vectored thrust agencies to hold up the remaining fraction of their weight, allowing them to hover.

If air cushion suspension is installed, usable surface area must be multiplied by 0.6 to allow for the tremendous space taken up by this suspension type.

Suspension

Type	*TL*	*Vol*	*Mass*	*Price*	*MW*	*Min Vol*
Air Cushion	6	4.2	0.84	.0042	0.1	1
Standard CG	9	0.5	0.4	.02	0.3	1
Improved CG	10	0.3	0.3	.025	0.2	0.3
High-Efficiency CG	12	0.3	0.2	.03	0.1	0.03

TL: Tech level available.

MW: Power requirement per displacement ton (14 kl) of hull.

Kl: Volume in kiloliters (cubic meters) per displacement ton (14 kl) of hull.

Mass: Mass in tonnes per displacement ton (14 kl) of hull.

MCr: Price in megacredits per displacement ton (14 kl) of hull.

Min Vol: Smallest installation volume allowed.

STEP 3. CONTROL SYSTEMS

Control systems fall into three categories: the actual vehicle controls, computers, and navigational aids. These are covered in detail in the Controls chapter (Section 4). Note that some control systems may not be installed on high-speed chassis.

The tech level of the control system must be equal to or greater than the tech level of the installed suspension.

CG-equipped vehicles require flight avionics and flight computers; air cushion vehicles do not.

STEP 4. LIFE SUPPORT

The type of life support required by a vehicle depends largely on its intended mission. A variety of options for life support are covered in the Life Support chapter (Section 11). If any extended accommodations are to be fitted (such as staterooms or bunks) they are installed at this time. Only vehicles intended for very long trips, days or weeks, are fitted with bunks or staterooms, and even then they are usually intended for use by several crewpersons in rotation.

STEP 5. ELECTRONICS

Electronics fall into four categories: communicators, sensors, electronic countermeasures (ECM), and electronic counter-countermeasures (ECCM).

Players should be familiar with the **Traveller** combat rules for how communicators, sensors, ECM, and ECCM systems work in order to decide which of these systems to install. All of these systems are covered in the Electronics chapter (Section 5).

STEP 6. WEAPONRY

Vehicles may be equipped with a wide variety of weapons. All of these are covered in the Weaponry section, beginning on page 91, except for defensive screens, which are covered in the Defenses chapter (Section 6). A number of special considerations apply to vehicle-mounted weapons, however.

Weapon Mounts: Vehicle-mounted guns do not require carriages, tripods, or other such mounts, as the vehicle itself serves as the mount. However, the type of vehicle mount and its location must be specified. There are five main types of vehicle mounts: chassis, turret, small turret, pintel, and open. As a sixth option, tac missiles may be mounted on the outside of the vehicle on launch rails.

Weapons in chassis mounts emerge from one of the six faces of the chassis. Although fine adjustments to their bearing and elevation is possible, gross weapon pointing is achieved by repositioning the vehicle itself.

A turret is a fully rotating armored compartment set onto the main vehicle chassis (it is usually on top of the chassis, but in the case of contra-grav vehicles, a turret could as easily be on the belly to allow the vehicle to fire at ground targets as it flies over them). The advantage of a turret is that it allows fire in any direction without without requiring the vehicle to be pointing or travelling in that direction. A turret (as opposed to a small turret) is one whose effective volume is more than 10% of the total chassis volume. Indirect fire weapons must be in either turrets or open mounts (see below). Although referred to simply as "turrets" in the basic rules, these will sometimes be referred to as "main turrets" in the rules below to distinguish them from small turrets, and from the aircraft-style turrets discussed below.

A small turret is usually on top of a turret, or in the case of a turretless vehicle, on top of the chassis itself, but it could be mounted on any face of the vehicle. Small turrets may have an effective volume of no more than 10% of the total vehicle volume. If a small turret is to be manned,

it must allocate volume for the crewmember equal to one-half the volume of the member's crewstation. Manned small turrets are also called cupolas, unmanned small turrets are referred to as *remote mounts*. Remote mounts are controlled from crewstations within the hull. The equipment necessary to remotely control the mount (periscopes, repeaters, etc.) is subsumed within the mass and price of the remote turret and crewstation (but see Step 8, Crew, below for fire control requirements).

Both types of turret have front, side, top (or in the case of a belly turret, bottom), and rear armor equal to those values calculated for the entire vehicle.

A pintel mount is a simple post or curved rail on which is mounted a light weapon, such as a machinegun or autocannon. It is usually mounted on top of the chassis or turret, and are particularly popular for open vehicles.

An open weapon is a large weapon mounted in the chassis of an open vehicle. Indirect fire weapons must be in either open mounts or turrets.

Lift vehicles may also mount weapons in any of the mounts listed in the Airborne Weapons Mounts chapter (page 152).

Fixed airborne mounts have no weight or drag. Main turrets have no drag points (as the drag of the turret is already calculated into the lower maximum speed of this chassis configuration). Hardpoints only have drag when ordnance or a bomb rack is mounted. Drag disappears when the weapons are dropped or launched. Airborne turrets from page 152 always incur a drag penalty.

Ordnance hardpoints are generally located on the top and sides of the chassis. Normally, a lift vehicle has room for up to four hardpoints on the hull top, although this is reduced to two hardpoints on turreted vehicles. All hull hardpoints count as inboard hardpoints from the Airborne Weapons Mounts chapter (page 152). Additional hardpoints can be mounted on stub wings, one attached to each of the vehicle's sides. Each stub wing can have one inboard hardpoint, one outboard hardpoint, and one wingtip launch rail.

Inboard wing hardpoints (and vehicle hull hardpoints) can carry up to 1500 kilograms of ordnance, or 7.5% of the total weight of the vehicle, whichever is greater, while outboard hardpoints can carry up to 500 kilograms of ordnance, or 2.5% of the vehicle's loaded weight, whichever is greater.

Multiple bomb/missile racks may be attached to each hardpoint, as well as single weapons.

Fuel drop tanks may be attached to inboard stub wing hardpoints if they have fuel-intake plumbing. Note that the Airborne Weapons Mounts chapter includes different values for plumbed and "dry" hardpoints.

Launch rails for missiles weighing no more than 100 kilograms may be installed on stub wingtips.

Stabilization: Stabilization gear enables a vehicle to fire its weapons while moving; see the Weapon Stabilization rules in the Fire Control chapter (Section 14) for characteristics.

Fixed forward-firing weapons do not require stabilization to fire while moving.

Mechanical Loading Assistance: A gun may reduce its requirement for loaders by having mechanical loading assistance for the gun. Mechanical loading assistance is covered in the actual weapon design sequences. Loading assisters have a volume of 1 cubic meter per ton and must be located with the weapons mount and the ammunition. (Note that with mechanical loading assistance the ammunition must be stored in the same part of the vehicle as the gun mount.)

Autoloader: Guns require one or more crew as loaders in addition to the gunner. All of the weapon's loaders may be replaced by an autoloader; weapons in remote mounts *must* have autoloaders. Autoloader characteristics are calculated during the weapon design sequence. Half of the autoloader's volume is in the part of the vehicle with the weapon mount and the rest is in the part of the vehicle where the ammunition is stored.

STEP 7. POWER PLANT

The vehicle needs a power plant to provide electrical energy to various subsystems, as well as to power the lifting agency. A variety of power plants are available and are detailed in the Power Production chapter (Section 8).

Grav and air cushion vehicles also require thrust, as their suspensions serve only to hold them up, not move them forward. The power plant on these vehicles is modified to provide thrust by the addition of propellers, a combustion chamber, or to power a more exotic maneuver drive. The variety of thrusters available is detailed in the Sub-Light (Maneuver) Drive chapter (Section 9).

Fuel tankage for the power plant and thruster are also calculated at this time.

STEP 8. CREW

Each vehicle crewmember requires a crewstation, and each passenger requires a seat.

Crewstations: Two types of crewstations are possible: cramped and open. Open vehicles may have cramped crewstations while enclosed vehicles must have open crewstations. Both types are listed in the Controls chapter (Section 4). The crewstations must be from the same tech level as the controls installed in Step 3.

Seats: Passenger seats are found in the Optional Features chapter (Section 7).

Each vehicle requires a driver. A vehicle commander is optional, but recommended on enclosed armored fighting vehicles. If the vehicle has a turret, the commander's station must be in the turret.

If one or more weapons are installed, a gunner is required, and one or more loaders may be necessary as well, as specified in the weapon design sequence. A gunner may fire more than one weapon, but may only fire weapons controlled from his station (called a *weapon station*). One station may control all weapons mounted on the same side of the chassis or in any part of a turret. One station is required for each small turret unless it is remotely controlled. One station may control any number of remote turrets, but one gunner may only fire one weapon per combat turn. A weapon station must be in the same part of the vehicle as the weapons controlled, except that a turret-mounted weapon may be controlled from the chassis, and remote-mounted weapons may be controlled from anywhere.

Fire Control: During the weapon design sequence, fire control systems are specified for various weapons. However, the designer should note that for vehicle-mounted weapons, fire control systems must be provided for each weapon station, not just for each weapon. For a vehicle with only one weapon and only one gunner, this distinction is immaterial, but if that same vehicle were designed to allow the gun to be fired from two separate weapon stations, each would require a separate fire control system.

If the weapon station controlling a weapon is in a different part of the vehicle from the weapon itself, the volume of the fire control equipment is divided evenly between the two locations.

Weapon stations that only control small arms or tac missiles do not require fire control systems. However, tac missile weapon stations are equipped with tac missile control units (see page 149).

STEP 9. CARGO

All remaining volume may be allocated to ammunition stowage, cargo space, or declared waste volume. Waste volume has no effect on the design.

Ammunition stowage has no cost, but adds the weight of the ammunition to the loaded weight of the vehicle.

Cargo volume has no cost, but adds to the loaded weight of the vehicle. Multiply the cargo volume, in cubic meters, by 0.25 to determine the addition, in tonnes, to the vehicle's loaded weight.

DESIGN EVALUATION

Once the design is complete, you will need to evaluate it to determine its game ratings.

1. Check Step

Go back and add up the volume, price, surface area, and mass of all the components. This is your chance to check to make sure that its internal occupied volume and area of surface fixtures are within what is allowed by the size of its hull. This step also provides you with a total price and mass.

2. Record Design Features

Most of the evaluation of your design will consist of recording the features already determined by the design, such as armor values, weapon statistics, installed electronics, crew, passengers, etc. Note the volume of the original chassis as its transport volume (the space it takes up in the hold of a starship or transport vehicle).

At the same time, total the price of the vehicle and its empty and loaded weights. Empty weight is the vehicle without any ammunition, fuel, cargo, crew, or passengers. This is essentially the weight of the vehicle as it comes off the assembly line, and is also what it weighs when being transported by another vehicle or starship.

Loaded weight includes a full load of ammunition, full cargo (assume 0.25 tonnes per cubic meter), and a weight allowance of 100 kilograms per passenger and crew. This is its typical operating weight.

Suspension Critical Damage Level: Only air cushion suspensions have a critical damage level (CDL, see **TNE** page 300); contra-grav vehicles simply use their hull armor.

CDL is equal to the air cushion vehicle's chassis volume (selected in Step 1) in displacement tons.

3. Determine Movement

Movement of lift vehicles is based on their thrust. The G rating of a lift vehicle is its total thrust in tonnes divided by 10 times its hull displacement (in displacement tons). Its maximum speed (in kilometers per hour) in an atmosphere is determined as follows:

If G = 1 or less, speed = (G × 3500) × Eff

If G = 2 or less, but more than 1, speed = {3500 + [1200(G–1)]} × Eff

If G = more than 2, speed = {4700 + [600(G–2)]} × Eff

Eff = chassis configuration efficiency (from Step 1)

Maximum speed cannot be greater than the maximum design speed of the chassis type. Maximum speed is reduced by drag and size of main turrets. Note the total number of drag points from the weapons mounts installed, again both with and without external stores and add the percent of chassis volume taken up by effective turret volume (see page 23). Reduce the maximum speed by 1% for each point.

Cruising Speed: A lift vehicle's cruising speed is 75% of its maximum speed.

Minimum Speed: Lift vehicles have no minimum speed. Contra-grav vehicles are assumed to have vectored thrust capabilities which allow them to hover.

NOE Speed: Only grav vehicles have an NOE speed. Grav vehicles have a safe NOE speed equal to the maximum allowed by their terrain-following avionics (40 kilometers per hour if no avionics are installed) or one-quarter of their maximum speed, whichever is less.

Combat Move: The safe NOE combat movement (in 10-meter grid squares per combat turn) is equal to the vehicle's maximum NOE speed (in kilometers per hour) multiplied by 0.139, rounded to the nearest whole number. The high mode combat movement (in 10-meter grid squares per combat turn) is equal to the vehicle's maximum flight speed (in kilometers per hour) multiplied by 0.139.

Travel Move: The high mode travel movement rate (in kilometers per 4-hour period) is equal to the cruising speed (in kilometers per hour) multiplied by 4. The NOE mode travel movement rate (in kilometers per 4-hour period) is equal to the safe NOE speed (in kilometers per hour) multiplied by 6.

4. Firing Characteristics

Record the firing characteristics of each mounted weapon as well as the effects of installed stabilization and fire control.

5. Determine Maintenance Points

Divide the loaded mass of the vehicle by the maintenance modifier appropriate to tech level as shown below:

TL	*Maintenance Modifier*
4-5	2
6-7	3
8-9	4
10-12	5
13-15	6
16+	8

Any lift vehicle which has two full-size computers (model St or Fb) installed should divide this result by 4 to get final maintenance points.

CHAPTER 4
Aircraft Design

There are three general types of aircraft: fixed-wing, rotary-wing, and lighter-than-air.

Fixed-wing aircraft depend on their airframes and their associated wings to produce the lift that enables them to fly. Fixed-wing aircraft may be propelled by any power source that produces thrust; unpowered fixed-wing aircraft are called gliders.

Rotary-wing aircraft rely on lift generated by rapidly rotating airfoils—rotor blades—in order to fly. The principal type of rotary-wing aircraft is the helicopter, which uses a power plant to spin its rotor and thus generate lift.

Autogyros are rotary-wing aircraft but with an unpowered rotor. Like fixed-wing aircraft, they generate lift by accelerating laterally and causing air to pass over their airfoil (which in this case happens to be a free-rotating rotor instead of a conventional fixed wing). As their configuration and operation are very similar to a fixed-wing aircraft, they are treated as a special case of fixed-wing design.

Lighter-than-air aircraft, called airships hereafter in this rule, include a range of craft from unpowered balloons to giant airships used as scheduled passenger liners or military reconnaissance and bombardment platforms.

All aircraft follow the same general design sequence outline, although the details differ depending on the type of aircraft being designed.

Step 1: Weight

Weight is the limiting factor in designing all aircraft. Weight is expressed in metric tonnes in one standard gravity (1G).

Fixed-Wing Aircraft: The weight selected by the designer for a fixed-wing aircraft is the aircraft's maximum weight without external stores. This includes the weight of the empty aircraft, a full internal fuel load, the crew, passengers, cargo, weapons, and ammunition.

Externally carried stores may increase the weight and add drag, affecting top speed. Up to 35% of the aircraft's maximum internal weight may be carried as external stores, depending on available *hardpoints*. The maximum internal weight plus its maximum external stores weight equals the aircraft's maximum takeoff weight.

Rotary Aircraft: The weight selected by the designer for a rotary-wing aircraft is its maximum takeoff weight.

Airships: The weight selected by the designer of an airship is its useful lift weight.

Step 1A: Envelope (Airships Only)

Lift generated by lighter-than-air gases and the volume needed to hold the lifting gases are the two constraints on the useful lift of an airship. Once the useful lift has been determined, calculate the envelope needed to produce that lift.

There are two types of envelopes possible, rigid and non-rigid, and three common types of lifting gasses, hydrogen, helium, and heated air.

A rigid envelope is constructed of a metal framework with a fabric (or, at higher tech levels, thin metal) covering. A non-rigid envelope is constructed of fabric without the metal frame. The table below shows the weight of both envelope types per displacement ton (14 cubic meters) of envelope according to tech level.

Hydrogen provides 15 kilograms of lift per displacement ton (14 cubic meters) in a lift envelope. Helium provides 14 kilograms per displacement ton and heated air provides 12 kilograms.

By subtracting the weight of the envelope per displacement ton from the lift of the gas in the envelope, the useful lift per displacement ton is derived. To determine the total volume of the envelope in displacement tons, divide the designed useful lift of the airship by the useful lift per ton of the envelope. The result is the total volume of the envelope in displacement tons.

These values, along with the prices of the envelopes, are summarized on the following table:

				Useful Lift (Atmosphere 6, 7)			
Type	*TL*	*Wt*	*MCr*	*H*	*He*	*HA*	*SM*
Non-Rigid	3	.007	.00014	.008	.007	.005	0.3
	4	.006	.00010	.009	.008	.006	0.5
	6	.005	.00015	.010	.09	.007	0.7
	8	.004	.00020	.011	.010	.008	0.8
	9	.003	.00025	.012	.011	.009	0.9
Rigid	4	.010	.00070	.005	.004	.002	0.6
	5	.009	.00080	.006	.005	.003	0.7
	7	.008	.00100	.007	.006	.004	1.0
	9	.006	.00200	.009	.008	.006	1.1

Wt: Weight, in tonnes, per displacement ton of envelope.

MCr: Price, in millions of credits, per displacement ton of envelope.

H: Useful lift, in tonnes, per displacement ton of hydrogen envelope.

He: Useful lift, in tonnes, per displacement ton of helium envelope.

HA: Useful lift, in tonnes, per displacement ton of heated atmosphere envelope.

SM: Speed multiplier. Multiply this value by the maximum speed on the Envelope Configuration table on page 28 to find the maximum speed at that tech level.

The lift values on the previous table are for an atmosphere with standard pressure (Type 6 or 7). Total lift is increased 20% in Atmosphere Types 8 and 9, which changes the useful lift to that shown on the table below. Lift is insufficient to produce a working airship in Atmosphere 5 or less.

				Useful Lift (Atmosphere 6, 7)			
Type	*TL*	*Wt*	*MCr*	*H*	*He*	*HA*	*SM*
Non-Rigid	3	.007	.00014	.011	.0098	.0074	0.2
	4	.006	.00010	.012	.0108	.0084	0.4
	6	.005	.00015	.013	.0118	.0094	0.6
	8	.004	.00020	.014	.0128	.0104	0.7
	9	.003	.00025	.015	.0138	.0114	0.8
Rigid	4	.010	.00070	.008	.0068	.0044	0.5
	5	.009	.00080	.009	.0078	.0054	0.6
	7	.008	.00100	.010	.0088	.0064	0.9
	9	.006	.00200	.012	.0108	.0084	1.0

Gaseous hydrogen costs Cr10 per displacement ton. Gaseous helium costs Cr30 per displacement ton on worlds where it is available. (Gaseous helium is available on about 50% of the worlds in the game.)

Once the type of envelope is selected, the configuration is chosen from the Envelope Configuration table on page 29. Five configurations are available.

Balloon: Balloon configuration is a non-rigid spherical gas bag from which a passenger or cargo compartment is suspended. Many balloons are tethered to the ground and are raised to provide elevated observation platforms. Non-tethered balloons are almost exclusively wind-driven and free-floating. Propulsion is difficult due to their bulky and unstable nature, but thrusters can move the balloon at low speeds.

Cigar: Elongated cigar-shaped envelopes are available in both rigid and non-rigid configurations. Cigar envelopes are equipped with fins for stability and steering, and so are much better suited to powered flight.

Cyclo-Crane: The cyclo-crane is a complex airship configuration in which the cigar-shaped envelope is pierced from front to back by a central shaft. Four (or more) pylons radiate from the central shaft and mount airfoils and engines on their ends (well outside of the envelope itself). These airfoils and engines can be turned to different angles to maneuver the craft or cause the bag to spin around its central axis, thus generating lift from the airfoils. The cabins and payload are suspended from cables attached to the ends of the central shaft.

Magnus Sphere: The Magnus sphere configuration consists of a spherical gas bag pierced through its center from side to side by a central shaft. The engines are mounted on the ends of the shaft and the cabin and payload are carried by conformal arms attached to the shaft. The engines can be rotated to give additional lift for takeoff, but the main lift augmentation comes from powered rotation of the Magnus sphere during flight (from the "Magnus effect," which provides lift to a spinning ball). Due to its compact nature, the Magnus sphere does not tend to weather vane in high winds and so is much safer in bad weather than conventional airships.

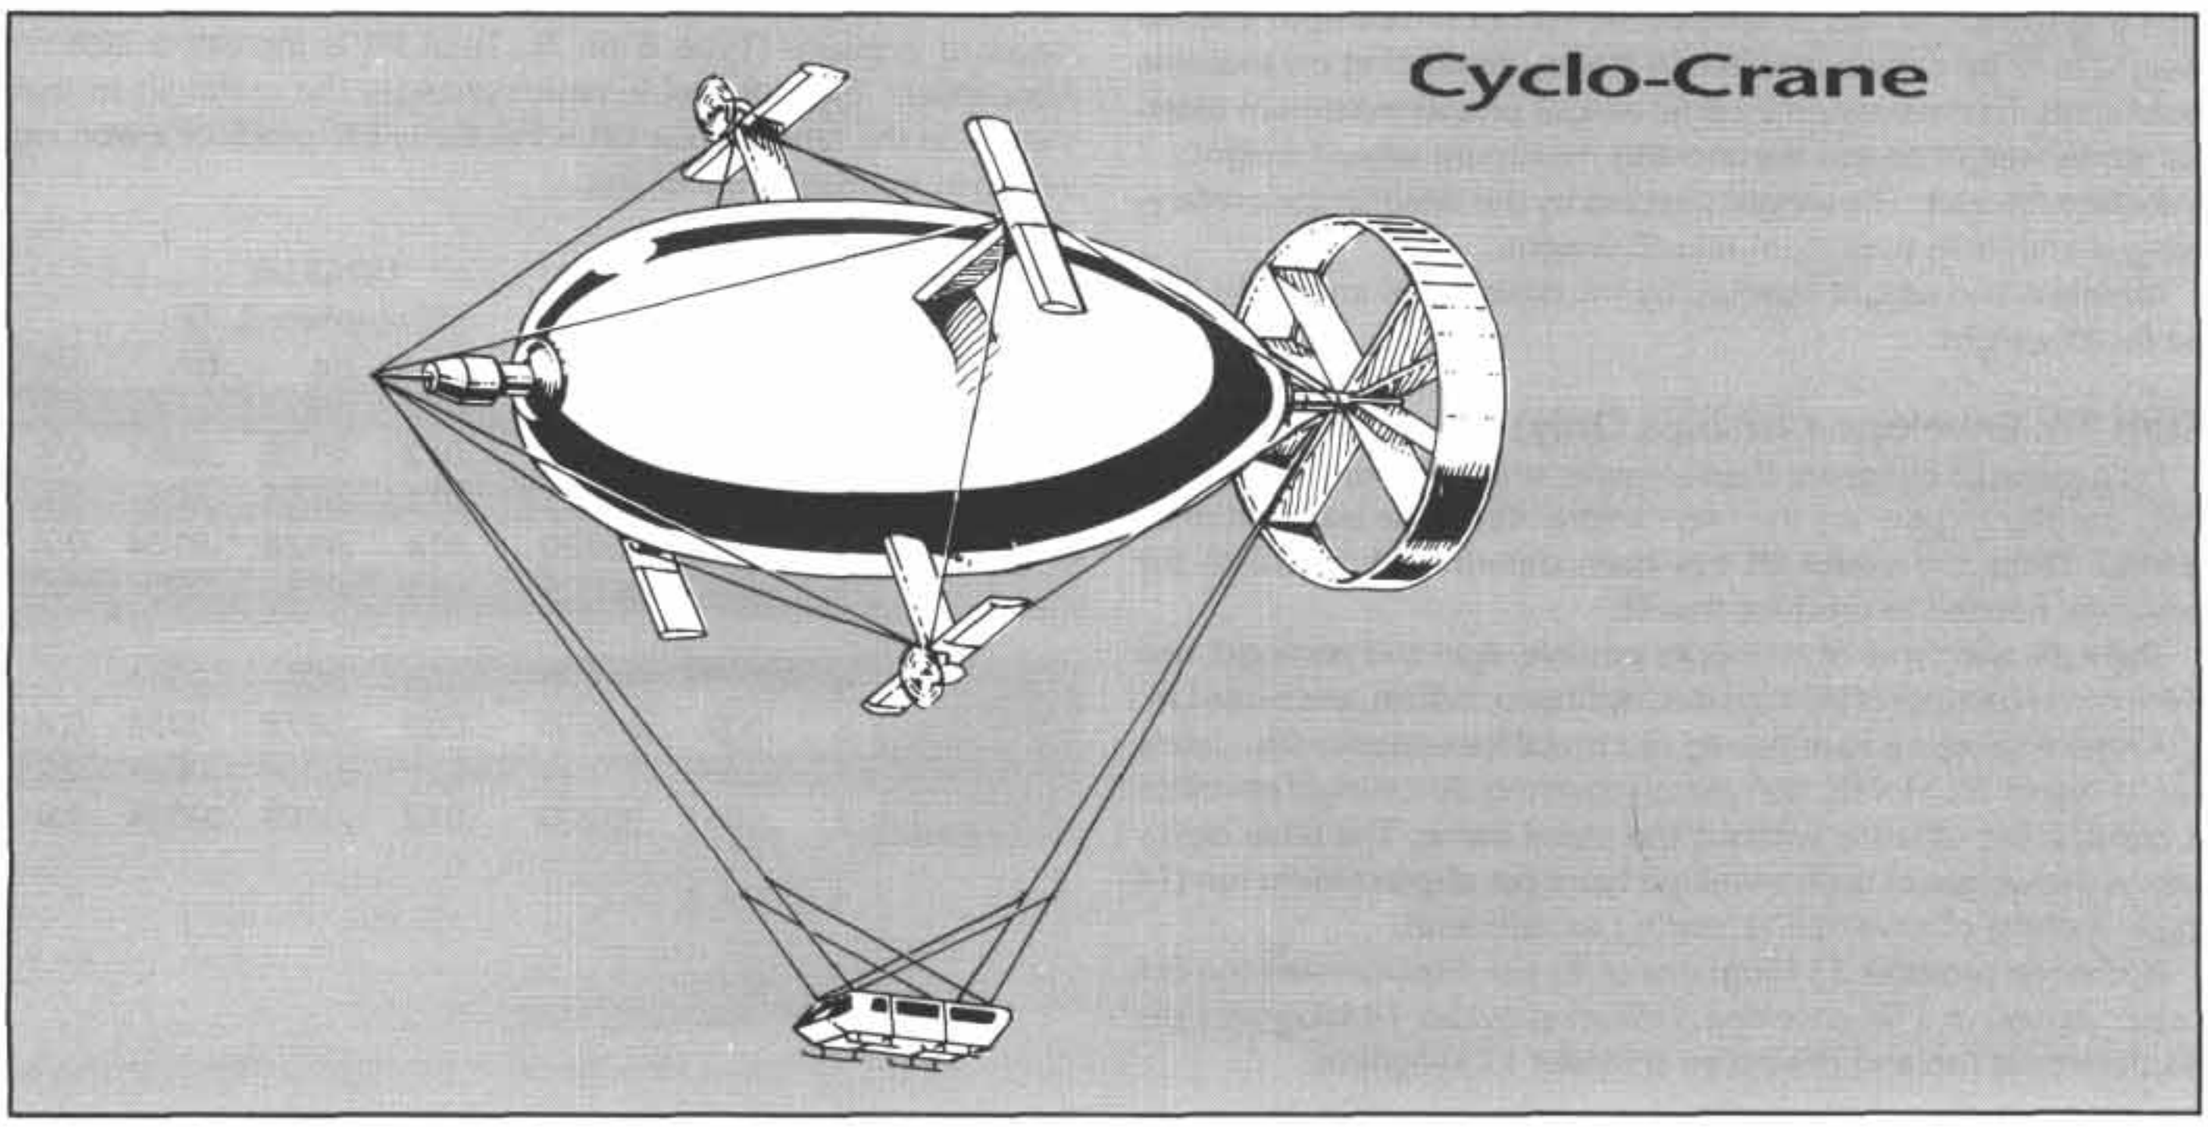
Airfoil: An airfoil airship is a rigid envelope constructed in the shape of an aerodynamic lifting body. The airfoil has a minimum speed necessary to gain its lift multiplier. This usually means that airfoil ships take off using conventional runways, but some cargo ships take off vertically without their cargo and then, when they have achieved their minimum speed for aerodynamic lift, snag their cargo from the ground using hook and line retrieval, carrying the cargo as an underslung load.

Note that the maximum speed by envelope configuration type is modified by tech level speed multipliers (and these vary between standard and dense atmospheres).

ENVELOPE CONFIGURATION

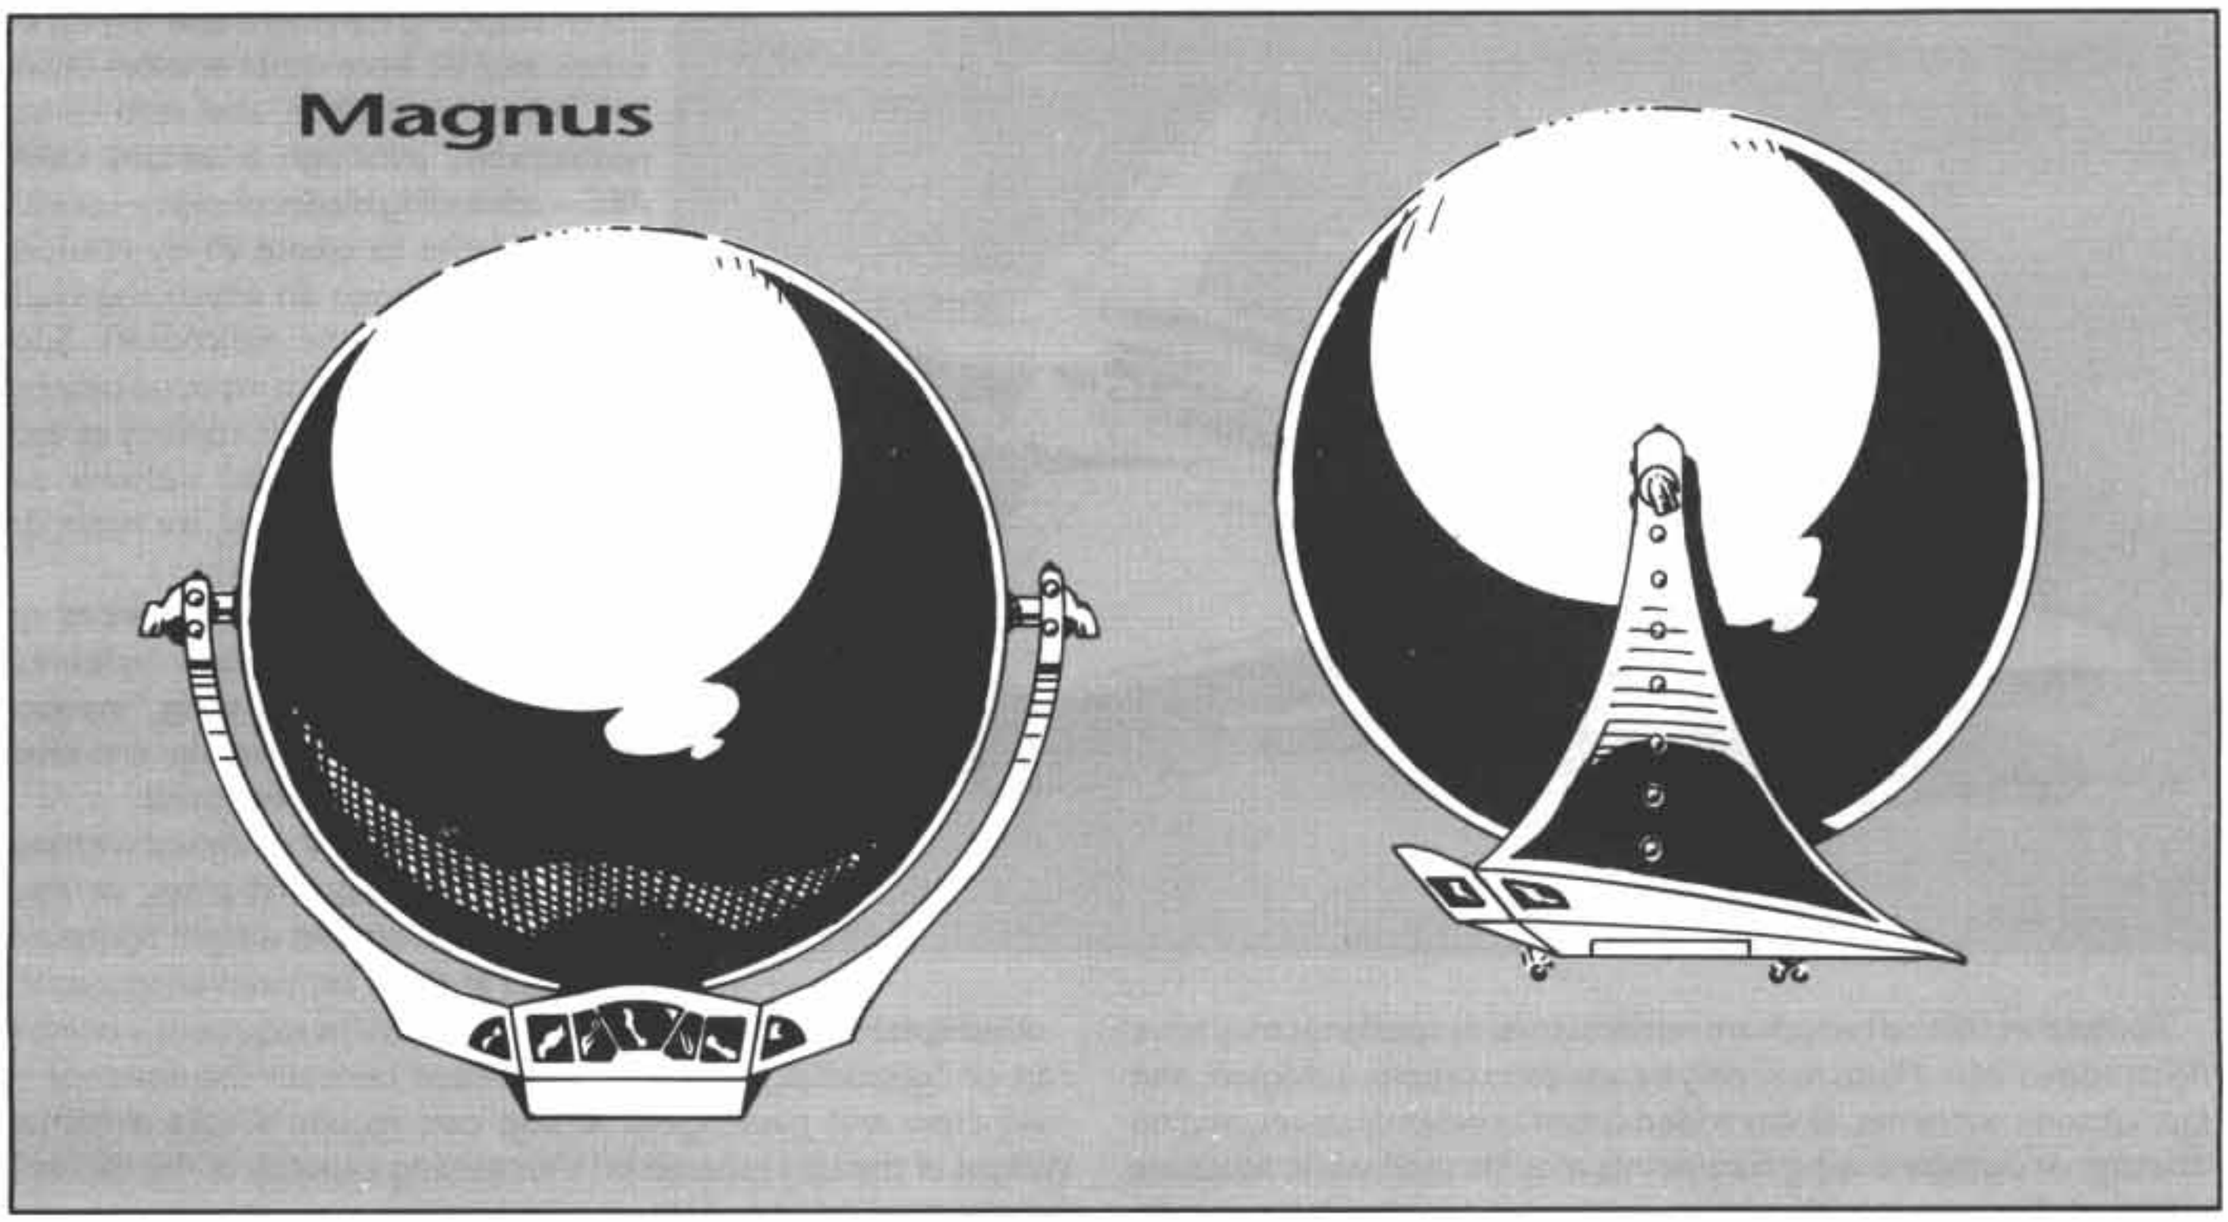
TL	Config	Type	Lift Mult	Wt Mult	Speed	MCr
3	Balloon	Non-Rigid	1	0.8	0/50	×0.8
4	Cigar	Both	1	1	0/200	×1
8	Cyclo-Crane	Non-Rigid	1.3	1.2	0/300	×2
9	Magnus Sphere	Non-Rigid	1.5	1.1	0/300	×1.5
9	Airfoil	Rigid	1.8	1.3	40/300	×1.3

TL: Tech level of first availability.



Config: Envelope configuration.

Type: Rigid, non-rigid, or both, indicating the type of envelope which can use this configuration.



Lift Mult: The total normal lift of the envelope is multiplied by this value to determine the maximum takeoff weight of the airship. The multiplier represents additional aerodynamic lift gained by the configuration.

Wt Mult: The total normal envelope weight is multiplied by this value to determine the actual envelope weight. Additions here represent additional internal structure necessary to achieve the indicated configuration. Note that changes in lift and envelope weight will necessitate recalculation of useful lift.

Speed: The minimum speed and maximum speed of the envelope

configuration. Note that maximum speed is adjusted by tech level speed multipliers found on the tables on page 27. Most airships have no minimum speed. The airfoil's minimum speed is that necessary to gain its aerodynamic lift multiplier.

MCr: The price of the envelope is its normal price multiplied by the value shown on the table.

Step 2: Airframe

Once the designer decides upon the aircraft's weight, he must select an airframe from the Airframes table (page 30). Each type of airframe has its own price per metric tonne of aircraft, minimum and maximum flight speeds, and efficiency factor (used in determining the aircraft's cruising and maximum speeds).

Fixed-Wing Aircraft: There is a wide variety of airframes, as there is a great spread in performance between different fixed-wing aircraft.

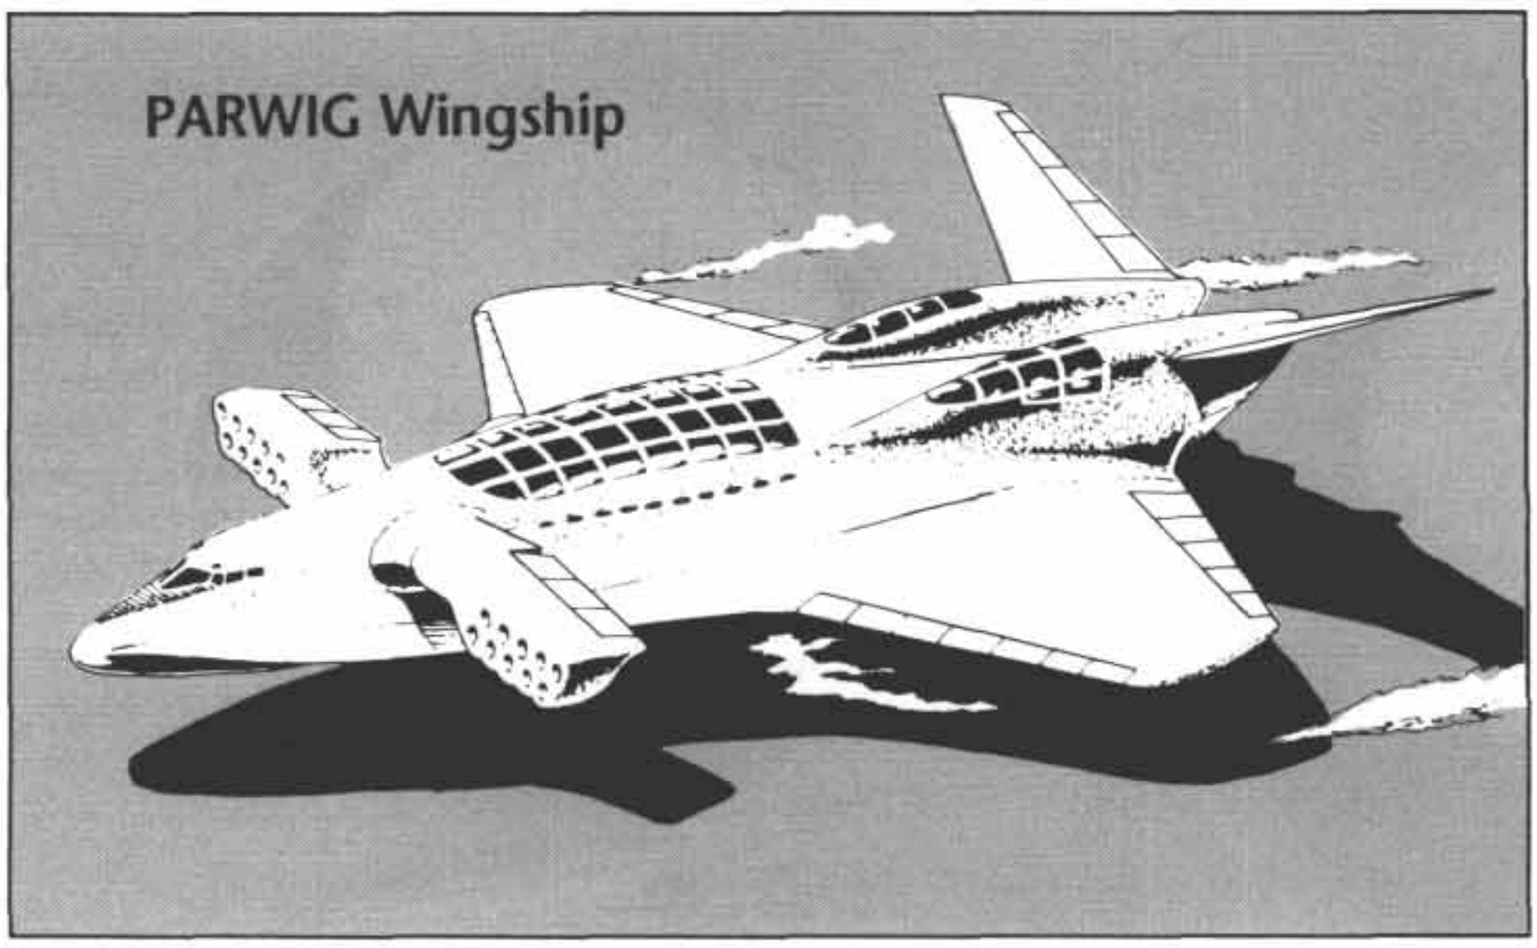
Autogyros: Autogyros are designed as if they were a special form of fixed-wing aircraft, using a unique airframe type. They are treated as fixed-wing aircraft in all other respects. Autogyro airframes may not incorporate STOL or VTOL capability, although they may incorporate seaplane capability.

Wing-in-Ground: Wing-in-ground (WIG) airframes are unusual airframes which allow truly immense loads to be carried. Wing-in-ground is a contraction of "wing in ground effect." Ground effect refers to the increase in performance experienced by all aircraft when flying within approximately half a wingspan of the ground. For conventional aircraft, long duration cruise in ground effect is not practical, but for specialized WIG craft, using the PAR (Power Augmented Ram) effect, it is, and creates dramatic increases in performance. The WIG airframes here are considered to be PARWIGs (WIG for short). These craft, also called "wingships," blow high-pressure air beneath their wings and use the increased lift resulting from the build-up of this high-pressure air between the ground and their lifting surfaces. This high-pressure air is essentially recycled back to the aircraft by the ground, rather than being dissipated through the air column beneath an aircraft flying at altitude. (Air cushion vehicles trap this air within their sidewalls or "skirts," while WIG aircraft create a rapidly dissipating bubble of high pressure beneath them as they move along.) Although they are able to generate enough speed that they can fly out of ground effect for short periods of time (in effect "hopping"), a WIG craft is distinguished by the fact that it cannot fly for any great distance out of ground effect (multiply fuel use by 5 during these short periods). As this effect can only be maintained over surfaces such as water, icecaps, or level ground, WIG vehicles are of rather specialized utility.

WIG craft may not be combined with STOL capabilities, but may be combined with VTOL and seaplane capabilities.

Gliders: Gliders are unpowered fixed-wing aircraft. Gliders always use simple airframes with STOL capability.

Fixed-Wing Options: Airframes may be modified for VTOL (Vertical Take-Off/Landing), STOL (Short Take-Off/Landing), or seaplane configuration.



VTOL: VTOL airframes incorporate either thrust vectoring gear for jets or tilt engine/tilt wings to allow the aircraft to take off directly upward then switch to normal flight. Add 10% to the weight and 50% to the cost of the airframe.

STOL: STOL airframes have longer, broader wings for greater lift, allowing shorter takeoffs and landings. Add 5% to the weight and 30% to the cost of the airframe. Add 10 drag points to the aircraft.

Seaplanes: Seaplane airframes add 5% to weight and 25% to the cost of the airframe. Seaplanes may only land on water.

Amphibians: Amphibian airframes (which may land on water or land) are built identically to seaplanes up to 350 tonnes aircraft weight. Between 350 and 400 tonnes, add no weight, but add 25% to cost. Above 400 tonnes, subtract 5% from airframe weight and add 25% to cost.

Floatplanes: Aircraft which are not designed as seaplanes may have floats added later. Floats may only be added to simple, autogyro, and fast subsonic airframes. Floats added count as external stores, and no fuselage or outboard wing hardpoints may be used while floats are attached. Floats weigh 5% of the total loaded weight of the aircraft, cost MCr0.01 per tonne of float, and add 20 drag points.

VTOL and STOL airframes are mutually exclusive. Seaplane capability may be added to either VTOL or STOL capability.

Carrier Aircraft: Aircraft may have the capability to fold their wings to allow them to be stored at a smaller volume. Add 5% to airframe weight and cost.

Beefing up airframe for aircraft carrier arrested landings costs a percentage of aircraft equal to 8.5% minus the aircraft's agility rating with a minimum percentage increase of 0.5%.

Adding corrosion resistance to aircraft adds nothing to weight and 5% to the cost of the airframe and power plant. Normal aircraft carried aboard ship or operating in a corrosive atmosphere require 5 times their normal MP to remain functional. Corrosion-resistant aircraft only require 2 times their normal MP.

Rotary-Wing Aircraft: Conventional helicopters require only a simple airframe, and indeed, can gain no performance benefits from faster airframes, as they cannot achieve speeds beyond the maximum allowed for a simple airframe. This is because of the particular problems created by the helo's rotor blades, of which two are significant: advancing blade tip speed and retreating blade stall.

Recognizing that the tip of each rotor blade is moving at a very high speed, it is not hard to imagine that a fast helicopter will soon run into the sound barrier with the tips of its forward-moving (advancing) rotor blades, which is an absolute limit on helicopter performance. The flip side of this is that as these same rotor blade tips spin a little farther and begin to move toward the rear of the helicopter (retreating), they begin to stall, losing lift at the same time that the blade tips on the opposite side of the helicopter are reaching the speed of sound.

Thus conventional helicopters are limited to 320 kph, which is the top speed of the simple airframe (even if it were to use a fast subsonic airframe, a conventional helicopter would still be limited to 320 kph). The key to higher performance is "unloading" the rotor, slowing down stopping it in flight and relying on thrust and lift from other sources (auxiliary jets or propellers, and stub wings, respectively, although a variant called ABC—advancing blade concept—uses stiff coaxial blades to create lift by ensuring that there is always an advancing blade on each side of the helicopter). Such helicopters are called compound helicopters. These can be built starting at tech level 6, and may use fast subsonic airframes. See Step 3, Thrust, for more details.

At higher tech levels, an advanced application of the compound helicopter becomes possible, the "X-wing," in which the stopped blades are heavier and more robust, and allow higher speed.

Helicopters may be designed with seaplane or amphibian airframes, or have floats added. Cost and weight figures are the same as those for fixed-wing aircraft.

Airships: In addition to the envelope, airships require one or more cars or "gondolas," inside or suspended beneath the envelope to hold crew and passengers. Airship cars require simple airframes. Weight of the cars is based on the carrying capacity of the car itself, not the total weight of the airship.

AIRFRAMES

TL	*Type*	*Aircraft*	*Wt*	*MCr*	*Min*	*Max*	*Eff*
4	Simple	Any	0.01	0.01	150/75	320	0.85
5	Autogyro	Fixed	0.005	0.02	40/—	200	0.65
5	Fast Subsonic	Fixed, Rotary	0.05	0.02	160/80	800	0.90
6	Transonic	Fixed, Rotary	0.10	0.03	180/90	1100	0.95
6	Supersonic	Fixed	0.20	0.04	280/140	2800	1.00
7	Hypersonic	Fixed	0.30	0.1	350/175	5000	2.75
7	Wing-in-Ground	Fixed	0.05	0.02	75/—	400	0.90

TL: Tech level of first availability.

Wt: Airframe weight, in metric tonnes, per tonne of aircraft.

MCr: Price, in millions of credits, per tonne of aircraft.

Min: Minimum speed, in kilometers per hour, of a conventional airframe/STOL airframe. Wing-in-ground and autogyro airframes have a single speed, as they may not be combined with STOL capabilities.

Max: Maximum design speed, in kilometers per hour, of the airframe.

Eff: Airframe efficiency, used in determining maximum and cruising speeds.

Surface Area: Each airframe has one square meter of useful surface area (for electronics and other similar surface installations) per metric tonne of aircraft. This is not true surface area, but is only the portion not already allocated to control surfaces, intakes, landing gear, etc., and therefore not suitable for surface installations.

Step 3: Thrust

Thrust propels an aircraft through the atmosphere. The mechanism by which an aircraft generates thrust is called its thrust agency. There are two general categories of common thrust agencies: propellers and jets.

Propeller-driven aircraft use the output from any power source to turn a propeller (sometimes called an air screw), which either pulls or pushes the aircraft through the atmosphere. Propellers require an atmosphere to function.

Jet-driven aircraft use the actual expanding gas of the combustion of fuel, sometimes combined with high-speed turbines, to create direct thrust. Provided a separate (and sufficient!) source of compressed oxygen is available, a jet thruster will work as well in vacuum as in an atmosphere.

A variety of thrust agencies are discussed in detail in the Sub-Light (Maneuver) Drive chapter (Section 9). Notice that many thrust agents have a limited number of airframe types on which they can be used.

Unpowered fixed-wing aircraft are called gliders. They are usually pulled aloft by another aircraft (of at least twice their weight; these are called *tugs*) and then released to glide to the earth. However, there are other methods, including catapult or even self-powered launch.

Rotary-Wing Aircraft: Helicopters are unique in that they rely on overhead rotors for lift as well as thrust. Helicopters need gearboxes, transmission assemblies, and rotors (all collectively referred to as the *rotor assembly*) to convert engine power to lift. Gearboxes reduce engine speed to rotor speed with reduction ratios of up to 90:1. Transmission assemblies link the power plant to the rotors, and rotors provide lift.

A rotor provides lift for the aircraft in addition to forward thrust. The total lift provided (determined by the size of power plant installed) must be equal to, or in excess of, the maximum take-off weight. The helicopter's thrust, in tonnes, is equal to its lift in tonnes multiplied by 0.1. If additional thrust is desired, an additional thruster (usually a turbojet or turbofan) may be added.

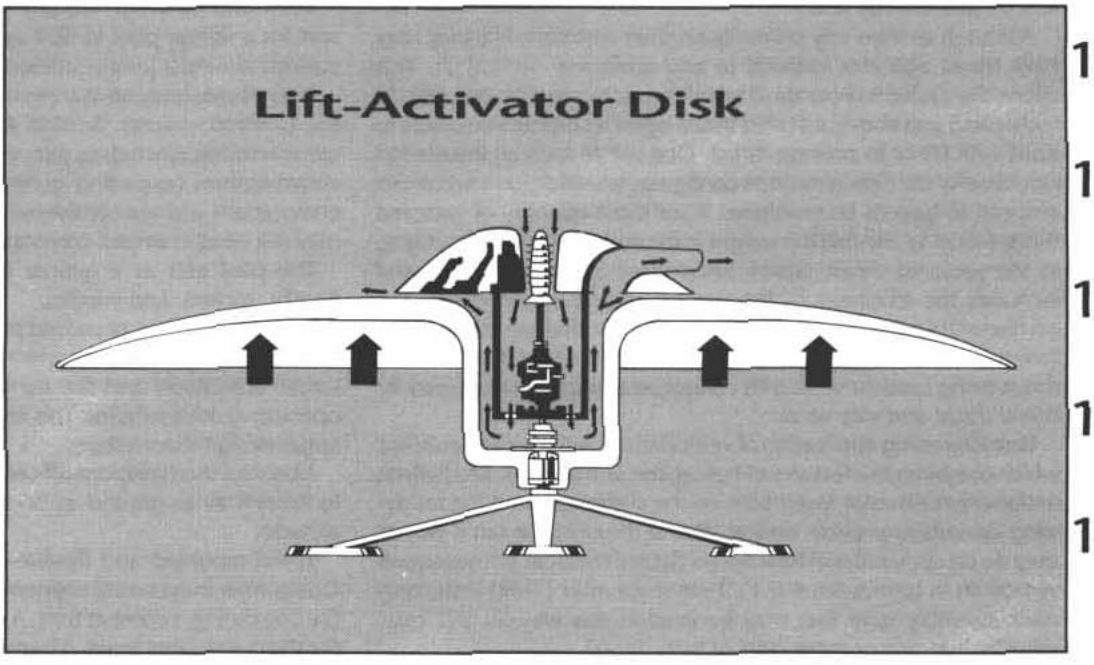
On a conventional helicopter, this added thrust plus the thrust from the rotor blades is limited to the top speed of 320 kph when speed is calculated in the design rating section, below.

Compound helicopters must have an added thrust agency, as their speed is calculated using this added thrust only. This added thrust must yield a speed at least equal to the minimum speed of the airframe. Compound helicopters at tech levels 6 and 7 may only use the MTR rotor configuration. At TL 8 they may use the CMR (depicting ABC technology) and MTR configurations.

TL 9+ compound helicopters use the X-wing rotor configuration.

Rotors come in several configurations, which in turn affect the number of rotor assemblies needed in a helicopter design. All of these configurations are designed to prevent torque from rotating the helicopter in the opposite direction of the rotor's rotation. The most common rotor configurations include the following:

Main and Tail Rotor (MTR): This assembly is a large, single main rotor and a much smaller anti-torque rotor which is mounted vertically to provide lateral thrust near the end of the tail boom. At higher tech levels, advanced versions of configuration are known as NOTAR, for NO TAil Rotor, in which vectored turbine exhaust takes the place of the anti-torque rotor.



Light MTR rotor assemblies are available for helicopters weighing two tons or less.

Twin Main Rotors (TMR): Two main rotors (or several pairs of main rotors in the case of really immense helicopters) on separate shafts that spin in opposite directions are mounted in such a way that their rotor blades do not interfere with each other. In some designs, the rotors are at the front and rear of the fuselage, with one rotor set higher than the other. In other designs, the rotors are mounted side-by-side at the ends of long outriggers, or are synchronized to mesh like eggbeaters.

Coaxial Main Rotors (CMR): Two main rotors spinning in opposite directions are mounted on the same vertical axis. This combines the advantages of twin counter-rotating rotors in a more compact configuration.

Lift Activator Disk (LAD): The "wing" consists of a revolving disk which spins around a fixed central cylindrical hub (which contains the crew, passengers, and power plant). The power plant draws air in from above the craft and then blows it across the top of the disk at high speed, generating lift. The spin of the disk (at about 1000 revolutions per minute) accelerates the air flow, further increasing lift. Part of the air flow is vented to the rear as thrust.

X-Wing: The X-wing helicopter is the ultimate expression of the compound helicopter. Going beyond merely unloading the rotors in flight, advanced materials technology allows a four-bladed rotor to be locked in flight so that its blades—two of them swept forward—now function as fixed lifting surfaces, allowing the aircraft to fly at high speeds, and then transition back to rotary flight for vertical

landings. X-wing configurations use the NOTAR system (see MTR, above) to counteract torque when in helicopter mode. X-wing helicopters use transonic airframes.

Ornithopter(ORN): Ornithopters are not rotary-wing aircraft, but their function is best described here. Ornithopters have mechanically articulated wings that flap like a bird's, providing both lift and forward thrust. Constructed of advanced light-weight materials, the ornithopter is still less efficient than a helicopter in rising to altitude, but can then lock its wings and function as a glider, conserving fuel and also allowing silent, stealthy approaches to a target.

Rotor Assemblies

TL	*Type*	*Wt*	*MCr*	*Lift*	*Max Wt*
5	Lt MTR	0.2	0.02	4	2
6	MTR	0.25	0.01	4	60
6	TMR	0.35	0.015	5	—
6	CMR	0.25	0.02	5	60
9	LAD	2.00	0.01	9	—
9	X-Wing	0.25	0.05	5	40
10	ORN	0.15	0.05	2.5	1
12	ORN	0.1	0.03	3	2

Wt: Weight, in tonnes, per tonne of power plant.

Reduce rotor assembly weight by 10% per tech level above its tech level of introduction (i.e., 90% of listed weight at one tech level higher, 80% at two tech levels higher, etc.), but never below 50% of the value shown on the table.

MCr: Price, in millions of credits, per installed tonne of rotor assembly.

Lift: Lift, in tonnes, per MW output of power plant.

Max Wt: Maximum take-off weight of a craft using that type of rotor assembly. This value increases by 10% each tech level above the original tech level of adoption.

Folding Rotors: Any helicopter may be given the capability to fold its rotor blades to reduce its storage volume by doubling the price of its rotor assembly.

Airships: Airships are typically powered by propellers, but may also be powered by jets.

Although airships rely primarily on their aerostatic lift, they may have thrust agencies installed to add additional vertical lift. This allows the airship to operate at weights greater than its useful lift. At tech level 5 and above, installed thrust agencies can be vectorable to assist with lift or to provide thrust. One use of such an installation would be for the airfoil envelope configuration which has a minimum airspeed to gain its lift multiplier. A sufficient quantity of vectored thrust (equal to *one-half* the weight in excess of the useful lift weight, as the vectored thrust takeoff takes place in ground effect, and increases the efficiency of the vertical thrust) would enable the airship to lift vertically off of the ground and transition to its minimum forward airspeed to gain its lift multiplier. Remember that vectored thrust being used for vertical lift cannot be at the same time used for lateral thrust and vice versa.

One interesting application of vertical thrust is the *helistat* concept which combines the features of helicopters and airships. The helistat designer installs rotor assemblies on the airship car, and the rotary-wing assemblies provide vertical lift and thrust in the same way as they do on conventional helicopters (lateral thrust in tonnes equals vertical lift in tonnes times 0.1). Twin main rotor (TMR) is the only rotor assembly type that may be used in this way (in this case, visualize it as one or more pairs of twin rotors).

If additional lateral thrust is desired, propellers or jets may be added in addition. Maximum speed is limited by the airship envelope configuration.

An airship with added vertical lift must have its weight re-defined. It now has a *maximum take-off weight* equal to its useful lift weight plus the value in tonnes of the added vertical lift.

Step 4: Power Plant

Propellers, rotors, and High Efficiency Plasma Recombustion (HEPlaR) thrusters require a separate power plant. Select the power plant or plants to power the aircraft. Available power plants are listed in the Power Production chapter (Section 8).

Certain types of jet thrusters (turbojets, turbofans, ramjets, scramjets, and rockets) are self-contained and do not require a separate power plant. Aircraft with self-contained thrusters will usually require some additional electric power. Each such power plant includes (without additional weight or cost) an electrical generator which will produce MW equal to the thruster's thrust in tonnes times 0.02. If additional power is needed, a small power plant will have to be installed.

Step 5: Controls

Select controls for the aircraft from those listed in the Control Systems chapter (Section 4). The tech level of controls installed must be equal to or greater than the listed tech level of the airframe and any installed thrust agencies, power plant, sensors, or avionics. If a computer is installed, it must have the same tech level as the controls.

Fixed-Wing Aircraft: Certain controls may not be used on certain airframe types, as noted on the Controls table in the Controls chapter (Section 4).

Rotary-Wing Aircraft: Helicopters larger than 10 tonnes require enhanced mechanical controls. All others require only basic mechanical controls, with all the above guidelines.

Airships: Unpowered airships (balloons) do not have controls. Powered airships require simple controls.

Step 6: Crew and Passengers

Crew and passenger accommodations can range from a single seat for a fighter pilot to 500 seats for passengers and four crew-stations aboard a jumbo jetliner.

Aircraft crew may be at crewstations, called cockpits for pilots (see the Controls chapter, Section 4). Aircraft with more than three crewmembers (excluding gunners) must have a flight deck, and all crewmembers (excluding gunners) must be provided with open crewstations and are considered to be grouped together. Gunners may still be at cramped crewstations.

The pilot acts as a gunner for fixed forward-firing weapons, bombs, rockets, and missiles.

A sensor operator, or second pilot who can act as sensor operator, is often included on aircraft which employ terrain-following radar, or target acquisition and fire control radar and high-performance, operator-guided missiles. This crewperson may also operate a laser target-designation system.

A bombardier/weapons officer is required if the aircraft is intended to launch air-to-ground attacks from higher than 2000 meters altitude.

Turret-mounted and flexible-mounted guns require a gunner. One gunner may control any number of remote turrets, but may only fire one during a combat turn. A gunner in a simple turret may only fire the guns in that turret. A gunner firing guns attached to a flexible

mount may fire only those guns during a combat turn, but may move to a second flexible mount to fire its guns, taking a full combat turn to move there.

A navigator is required if the aircraft's normal mission duration is six hours or longer. Navigators are not required in aircraft with tech level 7 or higher navigational aids and a flight computer.

A flight engineer is required in aircraft with three or more engines, or more than 3.5 MW devoted to propeller thrust, unless a flight computer is installed.

A copilot is required if the aircraft's normal mission duration is four hours or longer. A copilot is required on all commercial aircraft. A copilot is required for any aircraft weighing more than 25 metric tonnes unless a flight computer is installed.

All crew except pilot, copilots, and sensor operators may double as gunners. Passengers are provided with seats as found in the Optional Features chapter (Section 7).

Armor and escape devices listed in the Crew/Passenger Position Additions table may be added to any cockpit or crewstation. Transonic aircraft require ejection seats; advanced ejection seats are required aboard supersonic combat aircraft; and rocket-powered escape capsules are required aboard hypersonic aircraft.

Cockpit armor may negate the minor hit result of "1 crewmember." Check the penetration value of the weapon that hit. If it is less than the armor value, the minor hit becomes no effect.

CREW/PASSENGERS POSITIONS ADDITIONS

TL	Type	Mass	MCr
6	Ejection Seat	0.1	0.005
7	Adv. Ejection Seat	0.25	0.010
7	Rocket Escape Pod	0.50	0.015
4	Cockpit Armor (AV 2)	0.1	0.005
7	Adv. Cockpit Armor (AV 4)	0.15	0.010

Mass: Mass in tonnes.

Escape Systems: The mass and price of the ejection seat, advanced ejection seat, and rocket escape pod are the cost to add this feature to each crew and/or passenger station.

Step 7: Life Support

Aircraft flying above 3000 meters in a Standard atmosphere (5000 meters in Dense, 1500 meters in Thin) require life support systems. These range from oxygen tanks and masks to sealed cockpits and full pressure suits aboard combat aircraft to sealed cabins and basic life support (with emergency backup oxygen masks) for civilian airliners.

A variety of life support options are available and are discussed in detail in the Life Support chapter (Section 11).

Step 8: Weapons Mounts

The number of weapon mounts should be determined and the type selected from the Airborne Weapons Mounts chapter on page 152. Fixed mounts have no weight or drag. Hardpoints only have drag when ordnance or a bomb rack is mounted. Drag disappears when the weapons are dropped or launched. Turrets always incur a drag penalty.

Hardpoints are generally located beneath the fuselage and wings. Normally, an aircraft only has room for one fuselage hardpoint—usually the strongest of the hardpoints. Fuselage hardpoints can carry up to 2000 kilograms of ordnance or 10% of the loaded weight of the aircraft, whichever is greater. For large aircraft, assign one 2000kg hardpoint per *complete* 20 tonnes clean weight of aircraft. Hardpoints mounted farther outboard can carry less and less weight. Inboard wing hardpoints can carry up to 1500 kilograms of ordnance, or 7.5% of the loaded weight of the aircraft, whichever is greater, while outboard hardpoints can carry up to 500 kilograms of ordnance, of 2.5% of the aircraft's loaded weight, whichever is greater.

Bomb racks, each carrying up to six bombs, three rocket pods, or three launch rails with their missiles, may be attached to each hardpoint, as well as single weapons.

Fuel drop tanks may be attached to the centerline hardpoint or the inboard wing hardpoints if they have fuel intake plumbing. Note that the Airborne Weapons Mounts table includes different values for plumbed and "dry" hardpoints.

Launch rails for missiles weighing up to 100 kilograms may be installed on each wingtip.

Internal bomb and weapon bays hold one tonne of ordnance for each tonne of capacity.

Fixed-Wing Aircraft: Up to two inboard and two outboard hardpoints may be fitted to each wing.

Rotary-Wing Aircraft: As combat helicopters are intended for agile operations close to the surface of the ground, fuselage hardpoints are not used. Instead, standard wing hardpoints are mounted on stub wings. Each helicopter stub wing can have one inboard hardpoint, two outboard hardpoints, and sufficient wingtip launch rails to carry 100 kg of missiles. Weight and price of the stub wings is subsumed under the airframe.

Airships: As with helicopters, airships do not use fuselage hardpoints and instead mount their wing hardpoints on short stub wings, each with one inboard hardpoint, one outboard hardpoint, and one wingtip launch rail. Unlike helicopters, airships may have multiple stub wings along their length, allowing them to mount as much ordnance on hardpoints as they can lift. Stub wing weight and cost is subsumed under the gondola airframe.

Rigid airships may also have internal bomb bays: non-rigid airships may only have bomb bays *internal to their cars.*

Step 9: Weapons

A variety of weapons may be installed aboard aircraft. Machine-guns and CPR guns may be installed either in fixed, forward-firing mounts, or in flexible or turret mounts. Lasers and energy weapons may also be installed in fixed, forward-firing mounts.

Bombs may be installed in internal bomb bays. One tonne of bombs may be carried for each tonne allocated for internal bomb bays. They may also be attached to hardpoints either singly or in multiple racks. Rocket pods, gun pods, ECM pods, sensor pods, flare dispensor pods, napalm tanks, and fuel tanks may also be carried by the hardpoints. Missiles and larger free-flying rockets may be carried on missile launch rails that are mounted separately or are attached to hardpoints, and at tech level 7 and beyond they may be carried in retractable internal missile bays.

Ammunition for internally mounted guns is included in the overall aircraft weight. Ammunition for gun pods is included in the pods and counts as part of the external load.

Step 10: Electronics

Electronic systems of any sort may be installed on the aircraft, as detailed in the Electronics chapter (Section 5). Internally mounted systems count toward the total aircraft weight and the antennae must fit within the available surface area of the airframe.

External, pod-mounted systems incur a drag penalty and count toward the aircraft's loaded weight.

Step 11: Cargo

Aircraft may have weight allocated to cargo. Each tonne of cargo capacity allows the aircraft to carry one tonne of cargo.

Step 12: Fuel

Fuel capacity is measured in cubic meters. Each cubic meter of fuel masses one metric tonne except for liquid hydrogen (used in HEPlaR thrusters), which masses 0.07 tonnes per cubic meter.

An air-to-air refueling probe may be included in an aircraft's design. This allows the aircraft to refuel in flight from a tanker aircraft or another aircraft carrying a refueling pod as an external store.

Refueling probes cost Cr1000 and weigh 0.1 tonne. Refueling pods include a wind-powered transfer pump attached to an extendable hose and drogue, and a tank holding fuel for transfer. Refueling pods cost Cr5000 and weigh one tonne loaded per 1000 kg of fuel, with a 500 kg fuel minimum.

Step 13: Maneuver Enhancement (Fixed-Wing and Rotary-Wing Aircraft Only)

Designers may allocate any percentage of a fixed-wing or rotary-wing aircraft's weight to maneuver enhancement. There is no cost. The higher the percentage of weight devoted to maneuver enhancement, the more agile the aircraft.

Aircraft with more than 20% of their aircraft weight devoted to maneuver enhancement are assumed to be variable geometry aircraft of some sort. Variable geometry aircraft automatically count as having folding wings for purposes of storage and do not need to devote any additional airframe weight to that feature.

RATING YOUR DESIGN

Once you have designed your aircraft, you need to determine and record its ratings. These include weight, thrust, speed, agility, fuel use, endurance, range, price, and volume.

Weight: A fixed-wing aircraft's full internal weight, a rotary-wing aircraft's maximum take-off weight, and an airship's useful lift weight are the weights determined at the beginning of the design sequence (for helistats and airships with added vertical lift, use the maximum take-off weight discussed in Step 3). Be sure that total weights of all components, including fuel, cargo, ammunition, and ordnance in internal bays, do not exceed the specified weight. This is the aircraft's "clean" weight.

Fixed-wing aircraft also have a maximum gross take-off weight equal to its maximum internal weight multiplied by 1.35. This includes the full internal loaded weight plus externally carried stores attached to hardpoints.

Rotary-wing aircraft and airships may also carry ordnance on external hardpoints, but this does not add to their maximum take-off weight. That is, the weight of these weapons must have been anticipated from the beginning of the design.

Thrust: An aircraft's thrust is determined by its thrust agency and its installed power plant. Remember that a rotary-wing aircraft's thrust in tonnes is equal to its lift in tonnes times 0.1, plus any additional thrust agency incorporated.

Wing-in-Ground Aircraft: Multiply the effective thrust of wing-in-ground aircraft by 5.

Airships: Use thrust in tonnes divided by useful lift weight.

Glide Ratio: Fixed-wing aircraft, including autogyros, and ornithopters have glide ratios. The glide ratio is the number of meters forward an aircraft will glide for every meter it drops. All fixed-wing aircraft start with a glide ratio of 5 and add 1 to the ratio for every 5% of airframe weight devoted to maneuverability. STOL aircraft double their glide ratio. Once the final calculations are complete, subtract 1 from the glide ratio for every drag point (excluding the drag points for a STOL airframe).

All ornithopters have a glide ratio of 20.

Powerless helicopters attempt to "autorotate" to a soft landing, trading altitude for rotor speed, and have no meaningful glide distance. MTR and X-wing configuration compound helicopters calculate their glide ratios as fixed-wing aircraft. They are *not* STOL.

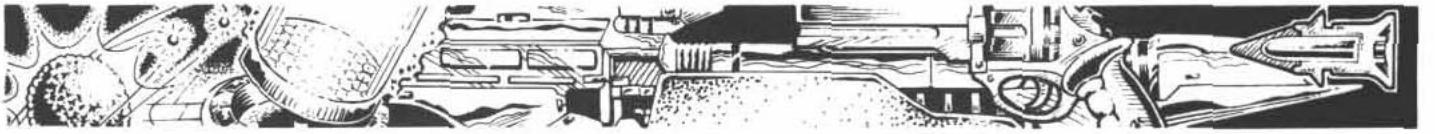
G Rating: An aircraft's G rating helps determine its top speed and agility. Calculate the G rating by dividing the aircraft's total thrust by its total weight (maximum take-off weight or useful lift weight for airships) and multiplying the result by the airframe efficiency factor (listed on the Airframes table, page 30). Airships do not have efficiency factors. For fixed-wing aircraft, calculate the G rating using both the aircraft's clean and maximum take-off weights (for two different G ratings).

VTOL aircraft must have a G rating of 0.5 or greater or they are instead treated as STOL aircraft. VTOL aircraft which have a maximum take-off weight G rating of less than 0.5 but a clean G rating of 0.5 or more are usually called STOVL (Short Take-Off Vertical Landing) aircraft, as they require a short take-off roll but can land vertically once they have released ordnance.

Speed: Maximum speed (in kilometers per hour) in an atmosphere is determined by the vehicle's G rating. Calculate maximum speed (for fixed-wing aircraft, calculate for each of the two G ratings).

If G = 1 or less, speed = G×3500

If G = 2 or less, but more than 1, speed = 3500 + (1200×[G–1])



If G = more than 2, speed = 4700 + (600×[G–2])

Maximum speed cannot be greater than the maximum design speed of the airframe type. Maximum speed is reduced by drag. Note the total number of drag points from the weapons mounts installed, and from use of a STOL airframe, again both with and without external stores. Reduce the maximum speed by 1% for each drag point.

As an example, an attack aircraft carrying four loaded, multiple-bomb racks under its wings and a drop tank under its fuselage would have 17 drag points. This would reduce its maximum speed while carrying these external stores by 17%. Once the bombs and tanks are dropped, the aircraft's maximum speed would increase to its full "clean" loaded speed or maximum airframe design speed, whichever is lower.

Airships: Given the low maximum speeds of airship envelopes, it is easy to overpower an airship. However, this power is not wasted. Airships are very susceptible to wind, and can get into a great deal of trouble in high winds, especially close to the ground. Such operations will require task rolls by the airship's pilot to not lose control of the airship and crash. Excess thrust beyond the airframe's maximum speed can be used by the pilot to reduce the difficulty level of such tests. Compute airship speed normally, and if the result is greater than the maximum speed, take the excess speed and divide it by the maximum speed, dropping fractions. The result is the number of –Diff Mods that can be used by the pilot to maintain control in bad weather.

For example, a tech level 7 non-rigid cigar envelope (standard atmosphere) has a maximum speed of 140 kph, and a useful lift of 10 tonnes. It is fitted with propellers generating 1.2 tonnes of thrust. This yields a G rating of 0.12 and a maximum speed of 420 kph. Maximum speed is limited to 140, so there is excess speed of 280 kph. Dividing this by 140, the result is 2, meaning that the design

gives the pilot 2 –Diff Mods for use in difficult weather or maneuvers. Add 1 to this result for cyclo-cranes and Magnus spheres, even if the result was 0.

Cruising Speed: An aircraft's cruising speed is 75% of its maximum speed.

Minimum Speed: An aircraft's minimum speed depends on the airframe type. Note its minimum speed on the airframe table. STOL aircraft have a minimum speed of half this. VTOL aircraft, most airships, and rotary-wing aircraft have no minimum speed. Minimum speed is reduced by 1% for each percent of a fixed-wing aircraft's weight used for maneuver enhancement.

NOE Speed: Only rotary-wing and VTOL fixed-wing aircraft fly the contours of the ground at nap-of-the-earth (NOE) speeds. NOE is defined as flying *around* ground obstacles, not over them, and must have the ability to hover. Airships, which may hover, are not responsive enough for NOE flight, and are too susceptible to wind effects. Aircraft have a safe NOE speed equal to the maximum allowed by their terrain -following avionics (40 kilometers if no avionics are installed) or one-quarter of their maximum speed, whichever is less.

Take-Off and Landing Rolls: All aircraft except for VTOL, helicopters and airships have take-off and landing rolls. These are the distances an aircraft must roll before taking off or after touching down.

To calculate take-off roll, multiply the square root of the actual take-off weight by the aircraft's minimum speed, then multiply the result by .25 and divide the result by the G rating of the aircraft. (However, if the actual take-off weight is less than 1 tonne, use it instead of its square root.) The result is the minimum safe take-off roll of the aircraft in meters.

To calculate landing roll, multiply the square root of the landing weight of the aircraft by the aircraft's minimum speed, then multiply the result by 0.6. (However, if the actual landing weight is less than 1 tonne, use it instead of its square root.) The result is the minimum landing roll of the aircraft in meters, but may never be less (in meters) than the aircraft's minimum speed (in kilometers per hour).

Combat Move: *The high mode combat movement (in 10-meter* grid squares per combat turn) is equal to the aircraft's maximum flight speed (in kilometers per hour) multiplied by 0.139. For VTOL aircraft, the safe NOE combat movement (in 10-meter grid squares per combat turn) is equal to the aircraft's safe NOE speed (in kilometers per hour) multiplied by 0.139, rounded to the nearest whole number.

Travel Move: The high mode travel movement rate (in kilometers per four-hour period) is equal to the cruising speed (in kilometers per hour) multiplied by 4. The NOE mode travel movement rate for VTOL aircraft (in kilometers per 4-hour period) is equal to the safe NOE speed (in kilometers per hour) multiplied by 6.

Agility: Agility is principally determined by speed.

Speed (kph)	*Agility*
22-42	1
43-85	2
86-171	3
172-343	4
344-687	5
688-1375	6
1376-2751	7
2752-5503	8
5504+	9

Add 1 to agility for every 10% of airframe weight devoted to maneuverability enhancement.

Calculate agility separately for NOE speed, maximum clean speed, and maximum loaded speed (where they are different). Aircraft flying NOE have their agilities doubled.

Agility serves as an increase difficulty modifier for fire against aircraft. An aircraft firing at another aircraft subtracts its agility from the target aircraft's to determine the difficulty modifier used.

Volume: A fixed-wing or rotary-wing aircraft's storage volume, in cubic meters, is equal to its weight in tonnes multiplied by 60. A fixed-wing aircraft with wing-folding capability has a storage volume of its weight in tonnes times 30, and a rotary-wing aircraft with its rotor folded or removed for transport has a volume equal to its weight in tonnes multiplied by 20. An airship has a volume equal to its envelope volume. Non-rigid, non-helistat airships can be disassembled for transport at a volume equal to 3 times its car/gondola mass in tonnes.

Volume determines target size difficulty modifiers, as shown on the table at the bottom of the page.

Fuel Use: The fuel use of each engine and power plant is obtained from the appropriate table in cubic meters per hour. If more than one engine or power plant is installed, multiply fuel use per engine by the number of engines installed to determine total fuel consumption.

Endurance: Endurance is the number of hours an aircraft can remain aloft at cruising speed. Divide the total volume of fuel carried by the fuel use per hour to determine the endurance, in hours, of the aircraft.

Range: Range is the distance an aircraft can fly at cruising speed. Calculate range by multiplying endurance by cruising speed. Do this for both clean cruising speed and loaded cruising speed, when they are different.

Price: Total the price of the aircraft's components to determine its total price.

Size	*Displacement Tons*	*Kiloliters/Cubic Meters*	*Diff Mod*
Sub-Micro (SM)	0-1	0-13	—
Micro (Mc)	1-9	14-139	—
Very Small (VS)	10-99	140-1399	–1
Small (S)	199-999	1400-13,999	–2

Large (L)	10,000-99,999	140,000-1,399,999	–4
Very Large (VL)	100,000-999,999	1,400,000-13,999,999	–5
Gigantic (G)	1,000,000+	14,000,000+	–6

Book 2: Subsystems

CHAPTER 1
Material Technology

Material technology deals with the progressive refinement of materials used in the fabrication of artificial structures. For game purposes, this relates primarily to vehicle, aircraft, and spacecraft hulls, but material technology has a hidden effect on the whole range of subsystem technologies covered in later chapters.

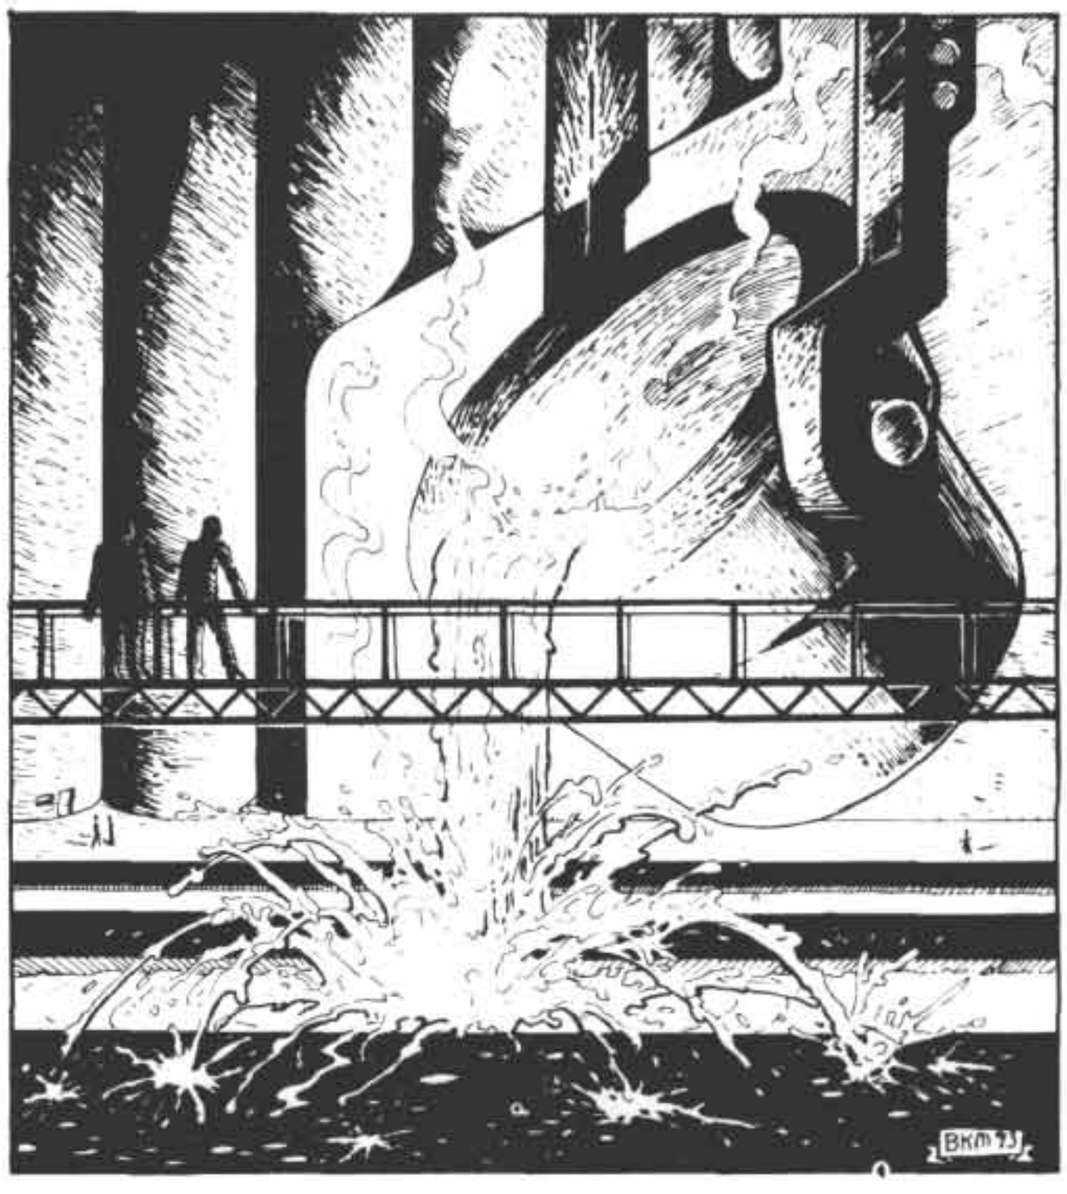
For example, metals with better resistance to fatigue allow the construction of high-speed propellers and fan blades, which simultaneously lead to more powerful aircraft propellers and high-performance turbines. Progressively harder metals form the basis of progressively more effective kinetic energy penetrators in tank gun ammunition.

The earliest metals appear at tech level 1, and consist of bronze (an alloy of copper and tin) and iron. Early iron is hand-forged and of low quality. By tech level 2, foundries are capable of making large solid-iron castings, but are still not capable of fabricating large vehicles or structures from iron subcomponents.

The placement of iron on the Vehicle and Craft Construction Materials table (page 38) at tech level 3 represents the first availability of industrially mass-produced iron from large foundries, along with early steel from the Bessemer process, and the ability to construct large vehicles with it. The first iron-hulled ships, as well as the first armored ships, are built at tech level 3. While steel is used for a number of subcomponents, it is still extremely difficult to use it in large constructions. (Steel is iron with carbon, and sometimes other metals, such as nickel, added for greater toughness and hardness.)

At tech level 4, steel becomes widely used as a replacement for iron in ship hulls, and the first primitive armored land vehicles appear. The first experiments with hardened steel are made, and by tech level 5, hardening techniques become reliable enough that face-hardened armor becomes widespread.

Face-hardened armor is an illustration of two competing values in armor plate which, for purposes of simplicity, we gloss over in **Traveller**, those values being hardness and toughness. Hardness is the ability of armor to resist any deformation at all, and it is usually associated with a certain brittleness. Toughness is the ability of the armor to absorb energy without shattering, and usually is associated with a certain elastic character. By way of illustration, glass is extremely hard but not very tough. Rubber is very tough but not extremely hard.



Armor which is very hard will cause small shells to shatter when they hit it and cause no damage, but larger shells will shatter the armor and pass completely through it. Tough armor can often be gouged or damaged by smaller shells, but does not suffer the massive shattering that hard armor does. Face-hardened armor combines both characteristics in one plate by taking a plate of very tough armor and hardening only the face of it. Small shots shatter against it while larger shots crack only the outer surface and are stopped by the more elastic part of the plate.

Although this is an interesting subject with some interesting effects on armor and protection, we have decided for purposes of game simplicity, to lump both characteristics into a generalized "toughness" rating, which represents the ability of armor to resist penetration by all projectiles.

At tech level 6, a number of alloys appear, which are different approaches to toughness and weight issues, as well as fiberglass, the first of the nonmetallic materials strong enough to consider for structural use. Light composites at tech level 7 represent a variety of additional nonmetallic structural materials, such as graphite, boron-carbide, etc. Early chobham armor is an example of light composite armor on vehicles.

Composite laminates at tech level 8 are matrices of different metallic and nonmetallic materials arranged to make the most of each material's strengths. The current version of armor used by US main battle tanks, which incorporates a mesh of depleted uranium in the composite armor, is similar to the level of protection shown on the table.

Crystaliron is a ferrous metal with perfect crystal structure and carefully controlled impurities in order to gain maximum hardness and toughness. Superdense is metal which has had its molecular structure partially collapsed in a massive artificial gravity field (such as might be encountered in a white dwarf star), which increases its density and strength. Bonded superdense has had its electron bonds artificially strengthened, by means of a field similar to that used in damper technology (see the Defenses chapter, Section 6). Bonded coherent superdense armor is dynamically manipulated by input from sensors and the computer so as to polarize the subatomic forces in the hull molecules, thereby presenting maximum penetration resistance to the specific striking weapon.

1. Vehicle and Craft Construction Materials

TL	Type	Toughness	Mass	Price (MCr)
3	Iron	1.5	8	0.0016
4	Soft Steel	1.7	8	0.0016
5	Hard Steel	2	8	0.002
6	Light Alloy	1.7	6	0.004
6	Fiberglass	0.25	1	0.001

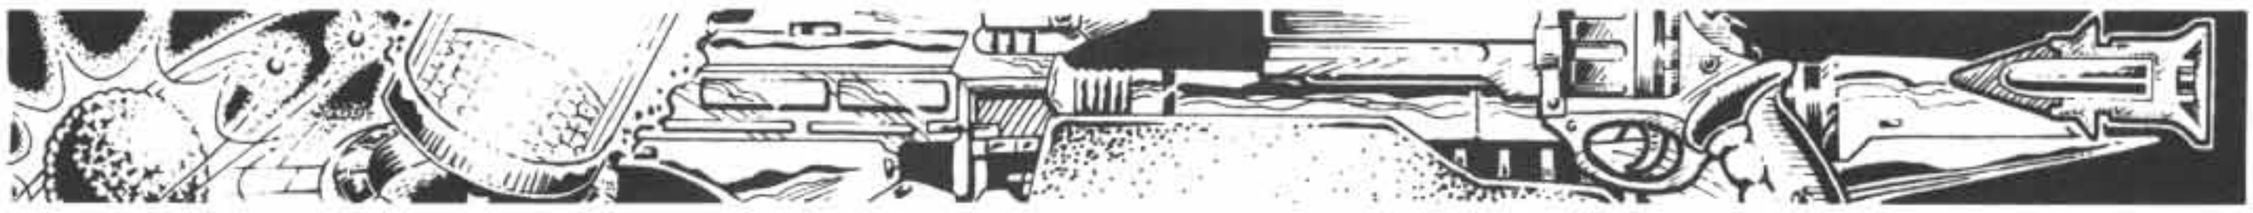
17	Coherent SD	40	15	0.035

The previous materials are those commonly used to build vehicles of various sorts and personal armor. For completeness, we offer the following list of common construction materials used to make buildings and fortifications. Price and weight are omitted as these vary considerably, and in any event are not relevant to the design sequences in this book. They are included so that referees may accurately judge the armor value and resistance to penetration of various field fortifications and civilian structures.

The table following this table lists, for convenience, the armor values of some commonly encountered forms of cover.

Toughness: A measure of the material's resistance to damage. A material's toughness times its thickness in centimeters equals its armor value.

Mass: Tonnes per cubic meter of the material.



Price: Price in millions of credits per cubic meter of material.

2. Construction Materials

TL	Type	Toughness
1	Loose Dirt	0.04
1	Stone, Packed Dirt	0.2
1	Wood	0.2
2	Masonry	0.3
4	Reinforced Concrete	0.4

3. Common Forms of Cover

Type	Thickness	Armor Value
Sandbag	25cm	1
2" Wooden Plank	5cm	1
Timber House Wall	20cm	4
Cinder Block Wall	30cm	9
Stone Wall	30cm	6
Thick Stone Wall	60cm	12
Reinforced Concrete	25cm	10
Tree Trunk	60cm	12
Brick Wall	10cm	3
Thick Brick Wall	30cm	9

CHAPTER 2
Personal Armor

Personal armor consists of solid or woven protection worn over various body parts. The design sequence deals with three types of armor: rigid, non-rigid, and powered. Rigid armor covers metallic and hard ceramic armors, while non-rigid covers leather, ballistic cloth, and ballistic weave. Powered armor is also called battle dress and consists of rigid all-body armor and a powered exoskeleton.

Rigid Body Armor: The designer will need to specify material, body parts covered, and thickness of protection. The first centimeter of armor can be made particularly tough through the use of surface-hardening, angling of the plates, and other techniques which serve to lower the effective weight of the first layer of armor proportional to its protection. This is reflected in the personal armor tables beginning on page 40, which apply only to the first centimeter of armor thickness.

The Rigid Body Armor table indicates the weight, in kilograms, per armor level of a particular armor type. For example, a soft steel piece of armor covering the chest weighs 7.8 kilograms per armor level. However, these weights apply only to the first centimeter of armor. The extra-tough first centimeter has been reached when the armor value equals the toughness rating of the armor type used. After that, additional armor value additions cost double the weight shown on the table.

In the case of fractional toughness values (such as with iron, soft steel, and light alloy), all armor weighs double after an armor value of 1 is reached.

Due to the need for fine-fitting work, rigid personal armor is fairly expensive. The price column on the table is the price, in credits, per kilogram of armor.

Armor Values: Armor value is determined by the thickness chosen by the designer. Although the armors shown provide information for an armor value of 1, values less than 1 may be selected by opting for thinner (lighter) armor than what is shown on the table.

Armor values of less than 1 but equal to or greater than 0.5 are treated as an armor value of 0. All armor with an AV of 0 has a parenthetical (melee only) value of 2. All armor with an AV of less than 0.5 has no value versus projectiles or energy weapons and has a parenthetical (melee only) value equal to its calculated AV multiplied by 4. Parenthetical melee values are rounded to their nearest increment of 0.5. (Since armor absorbs melee damage equal to twice its armor value, each AV of 0.5 absorbs one hit.) Armor with a parenthetical AV of less than 0.5 provides no protection.

Flexible Body Armor: Flexible body armor imposes fewer agility penalties than does rigid armor, but it is limited in the degree of protection it affords. (If too thick, it ceases to be flexible.) As a result, the flexible body armor lists the absolute armor value offered by that type of armor and the design decision involves selection of body parts to be covered. Price is, as with rigid armor, determined by multiplying the total weight (in kilograms) by the price listed on the Flexible Body Armor table on page 40.

Insert Plates: The Flexible Body Armor table also includes values for insert plates. These plates are inserted in pockets in ballistic cloth and ballistic weave jackets and vests. Plates may only be inserted over the chest and abdomen. When plates are inserted in these vests or jackets, the armor value of the plate is added to the protection of the vest or jacket.

Flak jackets already contain insert plates and their armor values take them into account.

Agility Penalties: Any armor covering the arms and/or legs causes an Agility reduction of 1. Any rigid armor (including flexible armor with plate inserts, which includes all flak jackets) covering part or all of the torso causes an Agility reduction of 1. These two effects are cumulative. Battle dress (see below) is excepted from this rule.

Initiative Penalties: Visored helmets cause an Initiative reduction of 1.

Storage Volume: Storage volume is the space taken up by armor when it is not being worn. This is generally used when a large amount of armor is being carried as cargo. Different pieces of armor have different storage volumes depending on what parts of the body are covered and whether the armor is rigid or flexible. The table below lists storage volumes in liters for different types of armor. Rigid armor consists of solid pieces of armor, usually metallic, although sometimes ceramic, articulated at the joints. Typical rigid armor is plate at lower tech levels and combat armor at higher tech levels. Semi-rigid includes armor which is made up of a large number of connected rigid pieces, and so is somewhat flexible. It includes chain mail, flak jackets, and ballistic jackets and vests with rigid armor inserts. Fabric includes leather, ballistic cloth, and ballistic weave. Note, however, that a ballistic weave helmet is rigid, and so has the same storage volume as listed for rigid helmets.

ARMOR STORAGE VOLUME (IN LITERS)

Type	*Rigid*	*Semi-Rigid*	*Fabric*
Helmet	1	0.5	0.5
Visored Helmet	2	—	—
Arms	5	0.5	0.5
Chest	10	1	0.5
Abdomen	10	1	0.5
Legs	15	0.5	1

Optional Features: Several optional features are possible.

Environmental Control: At tech level 9, environmental control may be added as an option. The environment control option includes an air-tight liner which gives complete protection against most chemical agents, tainted atmospheres, biological agents, and a moderate defense against radiation. A suit equipped with this liner is generally worn open at the neck and wrists, and can be sealed by donning gauntlets and a clear, flexible headpiece. Heat buildup in the suit is handled by a simple solid-state cooling system that is woven into the liner and which eliminates all infrared signature except on the exposed face, hands, and heat exhaust. The heat exhaust is a very pronounced IR source, but this can be dampened by

inserting a chemical chill can into the cooling system. The chill can completely eliminates the signature from 45 minutes to two hours, depending on the background temperature. At the end of that time, the can is used up and discarded.

When combined with a whole-body protective suit, the complete garment is usually called a combat environment suit. The environmental control option also results in a much more comfortable suit, with lower heat fatigue over time. Incorporation of environmental control reduces any agility penalty suffered by the armor by 1. (Armor with an Agility penalty of –2 becomes –1; armor with an Agility penalty of –1 loses its Agility penalty.)

The environmental control option costs Cr6000.

Helmet Sensor Suite: At tech level 10, compact sensor suites become available with sufficient resolution to negate the Initiative penalty associated with a visored helmet. These suites cost Cr750.

Chameleon Option: At tech level 12, a chameleon surface becomes available for any full-body armor. The chameleon option selectively bleeds heat to match background IR levels and effectively renders the wearer invisible to IR sensors. The chameleon option costs Cr1000.

Looking Glass Option: At tech level 15, a looking glass surface becomes available for any full-body armor. The looking glass surface changes color to match background colors and patterns, rendering the wearer nearly invisible when stationary. The suit adjusts gradually to its background (taking 1D20 combat turns to fully adjust), so while moving the suit has no more effect than camouflage fatigues.

The looking glass option costs Cr50,000.

Psionic Shield Option: At tech level 12, a psionic shield option is available as an addition to helmets. The option costs Cr4000 and adds negligible volume to the armor. At tech level 12, it adds 1 kilogram to the mass of the helmet, but at tech level 13 and beyond, the additional mass is negligible.

In-Helmet Communicators: Communicators may be added to helmets and armor packages by selecting a communicator from the Electronics chapter and adding its mass and price to the cost of the helmet or armor.

Advanced Sensors: Sensor suites may be added to armor by selecting a sensor from the Electronics chapter and adding its mass and price to the cost of the armor. The sensor data is displayed on the inside of the helmet visor or, if the helmet is not equipped with an armored visor, on the inside of a clear plastic faceplate.

ARMOR DESIGN TABLES

I. Rigid Body Armor Table

		Hit Location Covered								
TL	*Material*	*Tough*	*Chest*	*Abdmn.*	*Full Torso*	*Arms*	*Legs*	*Helmet*	*Visored Helmet*	*Price (Cr per kg)*
1	Iron	1.5	8.8	8.8	17.6	5.9	17.6	1.6	2.9	20
2	Soft steel	1.7	7.8	7.8	15.6	5.2	15.6	1.3	2.6	20
5	Hard steel	2	6.6	6.6	13.2	4.4	13.2	1.1	2.2	25
6	Light alloy	1.7	6	6	12	4	12	1.0	2	65
6	Titanium	3	4.4	4.4	8.8	2.9	8.8	0.7	1.5	125
7	Light comp.	4	3	3	6	2	6	0.5	1	100
8	Comp. lam.	6	2.4	2.4	4.8	1.6	4.8	0.4	0.8	100
10	Crystaliron	8	2.1	2.1	4.2	1.4	4.2	0.35	0.7	90
12	Super-dense	14	1.8	1.8	3.6	1.2	3.6	0.3	0.6	95
14	BSD	28	0.9	0.9	1.8	0.6	1.8	0.15	0.3	185
17	BCSD	40	0.6	0.6	1.2	0.4	1.2	0.1	0.2	235

Note: Although iron cannot be mass-produced until tech level 3 and the same is true for soft steel at tech level 4, both can be hand-forged in quantities sufficient for armor at two tech levels sooner.

II. Flexible Body Armor

			Hit Location Covered						
TL	*Material*	*AV*	*Chest*	*Abdmn.*	*Full Torso*	*Arms*	*Legs*	*Helmet*	*Price (Cr per kg)*
0	Leather	(1/2)	1	1	2	1	2	.5	10
1	Iron mail	(1)	5	5	10	3.3	10	1	20
2	Steel mail	(1)	4.5	4.5	9	3	9	.8	20
5	Flak jacket	1	6	6	12	—	—	—	15
7	Flak jacket	1	4	4	8	—	—	—	25
7	Ballistic cloth	1*	2	2	4	1.3	4	—	80
7	Plate insert	+1	2	2	—	—	—	—	25
8	Ballistic weave	1	2	2	4	1.3	4	.5	100

* Ballistic cloth is treated as no armor vs. edged melee weapons.

Battle Dress: Battle dress incorporates a powered exoskeleton which, in addition to allowing heavier armor, also doubles the effective strength of a human and moves at regular human speeds. The table below shows a variety of basic exoskeletons available at different tech levels. After selecting an exoskeleton, armor, batteries, and other equipment (e.g., integral weapons, oxygen tanks, etc.) are added up to the maximum allowed mass the exoskeleton can carry.

Each exoskeleton has a listed reduction in Initiative and Agility (except for the light TL-17 exoskeleton).

Designers may overload an exoskeleton if desired, but each additional 10% of mass reduces Agility and Initiative by an additional 1 and reduces movement by 10%. The exoskeleton may not be overloaded by more than 30%.

The rules on pages 39-40 on Agility penalties and benefits of environmental control do not apply to battle dress. Agility penalties and bonuses for environmental control are subsumed into the AGL penalties listed with the exoskeletons. All battle dress exoskeletons automatically include environmental control, as well as filter/respirator fittings which allow the wearer to function in thin and tainted atmospheres, as well as under chemical/biological warfare conditions.

However, battle dress does require an outside source of oxygen. For use in vacuum, portable life support systems must be worn (see **TNE**, page 337).

Powered Exoskeletons

TL	*SM*	*MM*	*MCr*	*SV*	*AGL*	*INIT*
10	0.25	0.56	0.077	100	–3	–2
12	0.1	0.23	0.111	100	–2	–1
12	0.2	0.4	0.152	120	–3	–2
14	0.05	0.21	0.153	100	–1	–1
14	0.1	0.4	0.255	120	–2	–2
17	0.05	0.3	0.2	80	—	—
17	0.1	0.6	0.3	100	–1	–1

TL: Lowest tech level of availability.

SM: Skeletal mass, the mass in tonnes of the rigid exoskeleton (including its power servos and supporting electronics).

MM: Maximum mass of the suit, in tonnes, including the skeletal mass, armor mass, and power supply mass.

MCr: Price (in millions of credits) of the exoskeleton. Total price of the battle dress unit will also include batteries and armor.

SV: Storage volume in liters of the empty armor. This includes space for power packs and armor.

AGL: The Agility penalty of the unit, assuming it is not overloaded.

INIT: The Initiative penalty of the unit, assuming it is not overloaded.

MW: Power requirement, in megawatts, equals the total mass of the unit (including power source and armor) times 0.014.

SAMPLE BATTLE DRESS DESIGNS

Tech Level 10 Battle Dress (AGL –3, INIT –2)

SM	*AV*	*AM*	*BV*	*BM*	*TM*	*MW*	*End*	*SMCr*	*AMCr*	*BMCr*	*TMCr*

None of these designs have been fitted with integral weapons, oxygen tanks, or sensors.

AV: Armor value.
AM: Armor mass (tonnes).
BV: Battery volume (cubic meters).
BM: Battery mass (tonnes).
TM: Total mass (tonnes).
End: Endurance of suit battery (hours).
SMCr: Skeleton price in MCr.
AMCr: Armor price in MCr.
BMCr: Battery price in MCr.
TMCr: Total price in MCr.

CHAPTER 3
Faster Than Light (FTL) Drives

Interstellar drives which allow avoidance of the limits of light speed form the basis of much science fiction. As there is no known way to avoid the light speed barrier, science-fiction authors (including game designers) must find ways to get characters from one star system to another expeditiously and using means which *seem* plausible given current scientific knowledge. After all, we do not yet know everything about the natural universe. Assuming that what we know is reasonably correct, what additional knowledge might enable FTL (faster-than-light) travel?

JUMP DRIVES

"Jump" drives enable starships to bypass the normal laws of time and distance by travelling from star to star through another form of space. The drives push a ship into a tunnel through jump space, or "J-space," a conceptual universe with more elastic dimensions than normal space (N-space). Due to the unique topology of J-space, the fall through the tunnel takes about one week (150 hours), regardless of the distance travelled in N-space. This time spent in the J-space tunnel is referred to as time "in the hole" by experienced travellers.

As gravitational fields interfere with the alignment of the jump drive (and may cause a jump mishap), ships do not usually jump until they are at least 100 planetary diameters away from the nearest world.

Jump drive machinery requirements are tied to the volume of the hull and the maximum distance the drive is capable of jumping the ship. There are upper limits on how many parsecs a ship may jump based on the tech level of the drive. The volume of the jump drives, as a percentage of the total volume of the ship, is equal to 1 plus the maximum jump number (in parsecs). So, for example, a ship capable of jump 4 would have jump drives which filled 5% (1+4) of the internal volume of the ship. If it were a 100-ton ship (1400 cubic meters of volume), the jump drives would take up 70 cubic meters of volume.

The Jump Drive table in the right-hand column lists the maximum allowed jump number, mass, and price of jump drives at each tech level.

Important Note: The smallest jump drive possible, at any tech level, is 2 cubic meters in volume.

Jump drives require fuel, displacement mass, and coolant, all of which are collectively called jump fuel (liquid hydrogen being used for all three functions). The fuel necessary for a jump of 1 parsec is equal to the total volume of the jump drive machinery multiplied by 5 and divided by the drive's maximum jump number. Thus, ships with higher jump performance make more efficient use of fuel at short distances. Jump fuel weighs .07 tonnes per cubic meter.

Fuel tankage itself is under Section 8, Power Production.

To continue the example of the 100-ton jump-4 ship above, it would require ($70 \times 5/4 =$) 87.5 cubic meters of jump fuel per parsec jumped (up to a maximum of 4 parsecs, the limit of its drive). The ship would normally have at least 350 cubic meters of jump fuel tankage (enough for its 4-parsec maximum jump).

JUMP DRIVE

TL	*Max Jump*	*Mass*	*MCr*
9	1	3	0.3
11	2	3	0.3
12	3	3	0.3
13	4	3	0.3
14	5	2.5	0.3
15	6	2	0.3

TL: Tech level of construction
Max Jump: The longest allowed jump in parsecs.
Mass: Mass in metric tonnes per cubic meter.
MCr: Price in millions of credits per cubic meter of jump drive.
Surface Area: Surface area in square meters equals cubic meters of jump drive ÷ 3.

ALTERNATIVE TECHNOLOGIES

The means by which FTL travel is accomplished is an important element, perhaps the single most important element, in defining a feel of a science-fiction campaign. The following FTL drives are not available in the Imperial Space campaign of **Traveller**, but instead are presented as alternative means of cracking the C-barrier.

Because the purpose of these alternative technologies is to allow referees to customize the background of their campaigns, the rules below should be seen as guidelines. Referees should feel free to change details to create the proper "look" for their campaigns.

Stutterwarp

Of all the possible forms of FTL travel, stutterwarp comes closest to physical travel though space at trans-light velocities. Stutterwarp is an implementation on the macro scale of the tunneling phenomenon common to electrons. The proper introduction of energy in a field around the ship allows it to move instantaneously from one location to another without passing through the intervening space.

The distances that the stutterwarp can travel in one warp, however, are very small. One cycle of the drive moves the ship less than a few hundred meters. But by cycling the drive very rapidly, the ship can travel vast distances in very short times, even faster than light.

Speed/Efficiency: Actual speed of a stutterwarp ship depends on the output of the power plant, the displacement of the craft that is being moved, and the amount of gravity through which it is being moved. In deep space, where gravity is less than

0.0001G, the warp efficiency is equal to parsecs per day. A warp efficiency 1 ship, for example, would require one week to travel between stars seven parsecs apart.

In the inner system of a star where the gravity becomes greater than 0.0001 G, the efficiency of the stutterwarp drops off enormously (by a factor of proximately 10,000). Ships with stutterwarp in the inner system are still moving at enormous speeds, but no longer at multi-light speeds. Stutterwarp-powered ships travelling between worlds in the inner system can expect travel times ranging from hours to, at most a few days.

Finally, when gravitation reaches about 0.1G, the efficiency of the stutterwarp drives drops off once again. At 0.1G, the stutterwarp has just enough efficiency to maintain orbit; above 0.1G, it cannot overcome the gravitational attraction and some other means of propulsion must be used. The major effect of this is that a stutterwarp drive cannot lift a vessel off of a world's surface or even out of its atmosphere. Some other type of engine is required, or the vessel may carry landing craft.

It is easy for a referee to determine at what distance from a planet or star these cut-off points are. Simply divide the body's surface gravity by 0.1G or 0.0001G (depending on which distance you wish to know), take the square root of that value, and multiply it by the radius of the body in kilometers. The result will be the distance in kilometers from the body's core at which the cut-off points are located.

For Sol, stutterwarp drives will not operate above light speed much beyond the asteroid belt, and they cannot overcome Sol's attraction at all if they are within 11.6 million kilometers of Sol's core (or about 10.9 million kilometers from Sol's surface). For Terra, the cut-off points are at approximately 638,000 kilometers and 20,000 kilometers.

Designing Stutterwarp Ships: Stutterwarps are available at tech level 10 and beyond. Stutterwarps require a separate power plant.

Volume: The volume of a ship's stutterwarp drive in cubic meters is equal to 2 plus the product of five times the square root of the output (in megawatts) from the power plant devoted to the drive.

$$V = 2 + (5\sqrt{MW})$$

Price: The price of the stutterwarp, in millions of credits, is equal to its volume multiplied by 0.3.

Performance: The efficiency of the stutterwarp is equal to the product of the tech level efficiency multiplier times the cube root of the quantity: megawatts (devoted to the drive) divided by 10 times the ship's displacement in displacement tons. The tech level efficiency multiplier of the stutterwarp is equal to the tech level of construction plus 4.

$$E = Tlm \times \sqrt[3]{MW \div 10D}$$

E: Efficiency
Tlm: Tech level multiplier (tech level + 4)
MW: Power input to the drive.
Surface Area: Surface area in m^2 equals volume in $m^3 \div 3$.

Stutterwarp Vessels in Combat: The stutterwarp is so much faster than conventional ships that it can literally "fly rings around" a G-maneuvering vessel. The craft's stutterwarp efficiency multiplied by 4 (rounding fractions to the nearest whole number) is the number of range bands (hexes if playing **Brilliant Lances**) it can move in *one minute*. Since a combat turn is *30 minutes* long, multiply the speed (in hexes per minute) by 30 to find out how many hexes it can move per turn. (This will range from 120 to as much as 500.)

To make the game manageable, divide the turn into several segments. If a stutterwarp ship is facing a conventional vector movement ship, divide the turn into as many segments as the current velocity of the vector-movement ship (or the fastest vector-movement ship if there are several). Divide the stutterwarp ship's movement by the number of segments in the turn. Each segment the stutterwarp ship moves that many hexes (or range bands) and the hostile ship moves 1 (or the fastest hostile ship moves 1 and the slower ones either move or pass, making sure they move the correct total number of hexes in the complete turn).

Ships may fire some or all of their weapons in any segment, but may fire each of their weapons only once per turn. Ships which have increased rates of fire (due to increased power to energy weapons) may use this to make extra shots instead of a blanket lowered difficulty level. This may allow an energy weapon to fire five or even 10 times in turn, but it may fire no more often than once per segment.

Regardless of how many hexes a ship moves in a segment, it may fire or be fired on at any point in its movement. As it moves each hex, the owning player should pause briefly to let any opposing player declare attacks.

If only stutterwarp ships are involved in the combat, divide the turn into 10 segments.

Charge Buildup Limitation (Optional): Stutterwarp as described above is a tremendously versatile drive system. Often the dictates of a game require some limitation on the versatility of a drive, particularly if a military situation is being gamed. The following limitation has been used by us in the GDW **2300 AD**™ future history. Its advantage is that it allows stars with planets to provide important way stations and choke points to travel. Without this option, it is very difficult to have a "frontier" between two powers. The first evidence of an invasion expedition would be the appearance of a hostile fleet in your capital's star system. Therefore, the following is highly recommended.

The structure of the stutterwarp drive imposes some limitations on distances travelled. As a stutterwarp drive tunnels, an energy charge builds up in its components. This charge is related to the total distance tunneled, rather than to the time the drive is in operation. When this charge reaches a critical threshold level, a rapid deterioration of the drive components begins, stalling the drive and releasing lethal radiation. The energy charge is removed by discharging it in a gravity well. If the discharge is not made by the time the ship has travelled its range value in parsecs, the ship will be completely irradiated and the crew killed. The discharge must take place in a significant gravity well of at least 0.1G, and it requires 40 hours to complete.

Note that in order to discharge into 0.1G, a vessel must be orbiting a body while discharging. Although 0.1G is also the limit at which stutterwarp drives drop below the efficiency of conven-

tional drives, stutterwarp drives are sufficient to make any velocity changes necessary to maneuver a ship that is in orbit, as long as the vessel does not drop below the 0.1G distance. Stutterwarp vessels can also leave orbit without using conventional drives.

Also, a stutterwarp vessel can use a planet to change its vector. To do so, the craft begins a shallow drop toward the planet. The velocity it picks up in this drop is sufficient to slingshot it past the planet and beyond the 0.1G limit, where its stutterwarp can be used to maneuver it away.

Wormholes

Wormholes are permanent or semi-permanent naturally occurring tunnels through space. They allow travel from one end of the wormhole to the other, and the hole may conceivably be of any length. Entry and exit points tend to be near large masses, such as stars or black holes. The fact that the wormholes can only be discovered, not created, lends a completely different topology to the universe. Wormholes are defined by two different characteristics: opening and length.

Opening: Wormholes may be open or closed, indicating the degree of difficulty encountered when trying to enter them. Whether all wormholes are open, all closed, or there are a mix of the two types is entirely up to the referee. Open wormholes can be entered without any unusual expenditure of energy, and in fact, are often discovered by accident. Closed wormholes can be entered only by great expenditures of energy and are more difficult to detect. (They are detected using densitometers.)

Ships enter closed wormholes by means of "keyhole" drives.

KEYHOLE DRIVE TABLE

TL	Mj	Vol
9	3	2
11	2.5	1.75
12	2	1.5
13	1.5	1.25
14	1.25	1
15	1	0.75
16	0.9	0.5
18	0.8	0.25
20	0.7	0.15

Mj: Power, in megajoules, required per displacement ton of craft.

Vol: Volume of drive, in cubic meters, per displacement ton of craft.

Price: All keyhole drives cost MCr0.3 per cubic meter of drive.

Mass: All keyhole drives mass 1 tonne per cubic meter.

Surface Area: Surface area in m^2 is equal to volume in $m^3 \div 3$.

In addition to the keyhole drive itself, the ship will usually have banks of capacitors to store energy from the power plant prior to the jump. Consult the Power Production chapter (Section 8) for a discussion of capacitors.

Length: There are two aspects of wormhole length which are important: endpoint length and apparent length. Endpoint length is the distance between the two endpoints (openings) of the wormhole, and determines the practical real-universe distance travelled through the wormhole. Endpoint length can either be determined randomly or deliberately set by the referee.

Apparent length is the time actually spent in the wormhole while travelling, and is up to the referee. Several options should be considered. One is a constant apparent length. That is, no matter how great or short the endpoint length, a constant amount of time is spent in the wormhole. (This is similar to the time spent in J-space when using a jump drive.) A second is a scaled apparent time, where the time spent in the wormhole is proportional to the endpoint length of the wormhole. A ratio of time to parsecs should be established, and it can be as little as one hour per parsec to a week or more per parsec. A third option is no apparent length: travel is instantaneous. A final option is random apparent length, the assumption being that wormholes are not necessarily straight mathematical constructs and may meander. Wormholes with short endpoint lengths may have very long apparent lengths, and vice versa. This option is perhaps the most interesting as it adds greater variety to the topography of your universe.

Stargates

There are two possibilities for including stargates in a game. One is the tightly closed-door wormhole opening and the other is the artificial (or "drilled") wormhole. Within these general classes there are a number of sub-varieties. When establishing a universe using wormholes as transportation routes, remember that it is not necessary that every variety discussed below be included. Some of the most interesting science-fiction universes are the most restrictive with respect to travel.

Closed Door: This really represents one more type of opening for a wormhole, and assumes that ships cannot easily carry equipment powerful enough to breach the wormhole opening. In this case, large gates are built at the wormhole openings which allow ships to pass through freely.

Drilled Wormholes: These stargates are nothing more than artificially created (rather than naturally occurring) wormhole openings. In some cases, stargates may be relics of long-vanished civilizations. There are two varieties of drilled wormholes: semi-permanent and transitory.

In the case of semi-permanent drilled wormholes, the builders determine entry and exit points, and a gate has to be built at both ends before the wormhole can be activated.

In the case of transitory wormholes, the gate serves as a very large directional-matter transporter which can teleport any object (including a ship) from the gate to any point within its maximum range. It essentially re-drills its wormhole every time it transfers volume. With that exception, all of the below considerations of stargate design must be addressed.

Characteristics: Stargates are usually huge and require tremendous power. If near a star, power is usually supplied by solar collectors, while fusion reactors provide power in other cases. Unlike most forms of technology, we offer few hard guidelines here and instead leave the details up to the referee. However, we will outline what sorts of requirements need to be defined.

Power requirements will be based on the displacement of objects passing though the gate, and will be expressed as Mj per displacement ton. The megajoules, rather than megawatt, nota-

tion is used as the gate is not continuously powered, instead only requiring a burst of energy when an object enters the wormhole through the gate. As a result, gates often have capacitor or homopolar generator banks (see Section 8, Power Production) banks which require recharging between ship entries.

Drilled wormholes are somewhat different, as both gates need to be continuously powered to maintain the wormhole between them. This power requirement is in MW per parsec of endpoint length.

The actual gate structure is heavy with complex electronic components, and has a volume equal to one displacement ton (14 cubic meters) per displacement ton capacity. That is, 1000 tons of machinery are required for a gate large enough for a 1000-ton ship to pass through. Gate structure costs between MCr0.001 and MCr1 per displacement ton (at the referee's discretion) and masses 1 tonne per cubic meter (14 tonnes per displacement ton).

Stargate Characteristics Summary

Gate Opening Energy: Mj per displacement ton
Gate Sustaining Power: MW÷parsec endpoint length
Gate Capacity: In displacement tons
Gate Volume: Gate capacity × 1.
Gate Mass: Gate capacity (in displacement tons) × 14.
Gate Price: Gate volume multiplied by the cost constant.

Gate performance is affected by tech level. Tech level can provide both progressive increases in efficiencies and can also impose upper limits on endpoint length. It may also reduce the gate volume to a decimal multiplier of the gate capacity, such as 0.8 or 0.1.

The table below is a sample description of what gate technology might be in a science-fiction universe.

Stargates

TL	*EPL*	*GOE*	*GSP*	*Vol*
10	6	20	100	1
11	7	18	100	1
12	8	16	100	1
13	9	14	100	1
14	10	12	100	0.9
15	12	10	100	0.8
16	15	9	100	0.7
18	20	8	100	0.6
20	25	7	100	0.5
21	30	6	100	0.4

TL: Tech level of availability.
EPL: Maximum endpoint length in parsecs.
GOE: Gate opening energy in megajoules per displacement ton of transferred volume.
GSP: Gate sustaining power in megawatts per parsec of endpoint length.
Vol: Volume of gate machinery, in displacement tons, per displacement ton of transfer capacity.
Gate Mass: The mass of the gate, in tonnes, is equal to the volume of its machinery in displacement tons multiplied by 14.
Gate Price: The price of the gate, in millions of credits, is equal to the volume of its machinery in displacement tons multiplied by 28.

Subspace

Subspace is a duplicate of our physical universe in smaller scale. Ships which enter subspace can move from point to point at sublight speed, but arrive at their destination sooner than in normal space because the distance travelled is less. In this respect, subspace bears some similarities to J-space (see the discussion of jump drives above), but with some very important differences.

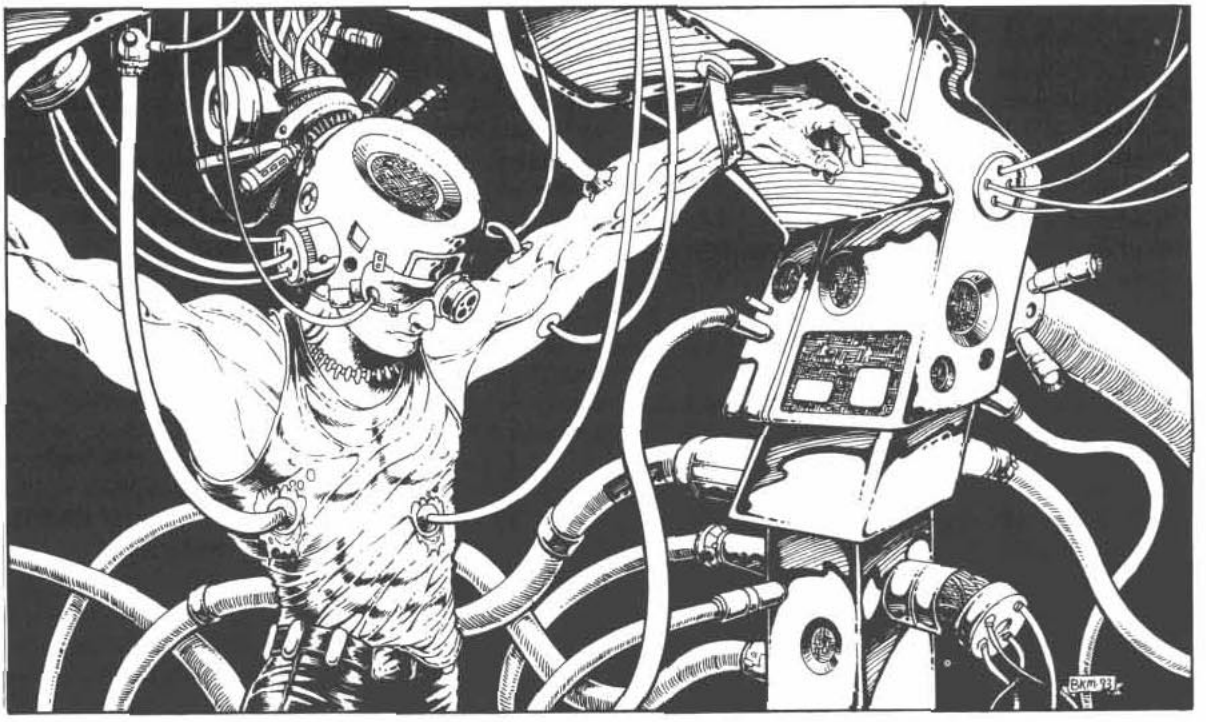
Subspace does not resemble a vacuum, but instead resembles a fluid medium. Continuous energy is required to sustain forward motion through the resisting medium. In addition, each point in subspace has an analogous point in normal space (N-space) and a ship whose subspace drives fail will immediately reappear in N-space at the point corresponding to its previous subspace location. This also means that, although power is usually consumed in relation to speed, a certain amount of energy is consumed simply remaining in subspace, even if absolutely stationary, and this is called the "station-keeping" power level.

Subspace drives require separate power plants. The amount of energy channeled to the subspace drive, coupled with the efficiency of the drive, determines the speed of the craft.

A variable volume of subspace drives may be installed, the volume of the drives limiting the total power that can be used in the drive. The drive's speed is determined by dividing the power (in megawatts) by the displacement (in displacement tons) and multiplying by the tech level efficiency modifier.

$$V = (MW \div D) \times Eff$$

V: Velocity
MW: Power input in megawatts
D: Displacement in tons
Eff: Tech level efficiency multiplier



The volume requirements, prices, and efficiency levels should be determined by the referee. As with the case of stargates, we present the following table as one example of subspace drives, but remind referees that they are free to change these values as much as desired.

Subspace Drives

TL	*Vol*	*Eff*
9	0.50	0.60
10	0.40	0.65
11	0.30	0.70
12	0.25	0.75
13	0.20	0.80
14	0.15	0.85
15	0.10	0.90
16	0.08	0.95
18	0.06	1.00
20+	0.04	1.10

TL: Tech level of construction
Vol: Cubic meters of drive per MW of power input.
Eff: Drive efficiency multiplier.
Mass: The mass of the drive, in tonnes, is equal to its volume in cubic meters.
Price: The price of the drive, in millions of credits, is equal to its volume, in cubic meters, multiplied by 0.25.
Surface Area: Surface Area in m^2 equals volume in cubic meters ÷ 3.

Subspace Drive and Combat: Normal Traveller starship sensors and communicators are useless in subspace. Consult the Electronics chapter (Section 5) for alternate equipment which is used in subspace. Missiles (unless built with subspace drives), sancasters, and force fields are likewise useless. Lasers, meson guns, and particle accelerators may be used normally. With the exception that different weapons, sensors, and communicators are used, the only other difference is that each range band (hex in **Brilliant Lances**) is 0.01 parsec (0.0326 light-years), approximately 1 million light-seconds. Spacecraft combat speed in range bands (hexes) per turn is equal to their subspace travel velocity multiplied by 200 (rounding fractional results to the nearest whole number).

Psionic Transfer Drive

Psionic transfer (PT) drive uses a conventional power plant to artificially augment the psionic teleportation skill of a psion. This technology normally assumes a cybernetic man-machine interface (usually by neural jack), but it can also be accomplished with computer empathy. Although machinery cannot duplicate the subtlety of a psionic field, it can amplify and strengthen it, which is what the psionic transfer drive does.

The normal requirement that the psion have foreknowledge of the destination is still in effect, which limits the number of psions capable of running a PT drive significantly. Usually both Teleportation and Clairvoyance skills are required. At tech levels 16 and above, the astrogation computer can store direct neural images of the location with sufficient clarity that psions can use them in place of normal sensory input to orient themselves for the transfer.

No one burst of energy characterizes the PT drive, but it must run for a number of hours prior to the transfer equal to the planned transfer *distance (in parsecs)*, and a like number of hours are spent in transfer.

Range is determined by psionic power. The maximum psionic teleportation transfer range, in parsecs, is equal to the square root of the psionic power rolled for the task. Psions may attempt to transfer for distances greater than can be guaranteed (the square root of the psion's Psionic Strength and Teleportation skill level), but if the additional D10 roll is insufficient to reach the destination, a misjump occurs. Consult the **Traveller** main rules for the rules concerning misjumps.

Note that psions often use Psi Booter when conducting PT operations.

The volume requirements, prices, and efficiency levels should be determined by the referee. As with the case of stargates, we *present* the following table as one example of PT drives, but remind referees that they are free to change these values as much as desired.

PT Drives

TL	*Vol*
9	0.10
10	0.09
11	0.08
12	0.07
13	0.065
14	0.06
15	0.055
16	0.05
18	0.045
20+	0.04

TL: Tech level of construction

Vol: The volume of the PT drive is equal to the volume of the craft multiplied by the value shown on the table.

Mass: The mass of the drive, in tonnes, is equal to its volume in cubic meters.

Price: The price of the drive, in millions of credits, is equal to its volume, in cubic meters, multiplied by 0.25.

MW: The power required for the drive, in megawatts, is equal to its volume in cubic meters.

CHAPTER 4
Controls

Controls, for the purposes of these rules, include control systems proper, navigational aids, computers, and workstations.

CONTROL SYSTEMS

Control systems include control consoles from which the crew of a craft control its systems, and the interior circuitry linking the craft's electrical and mechanical systems to those controls. Installed computers must be from the same tech level as the controls, and avionics and navigation aids may not be installed from a tech level higher than that of the controls.

CONTROLS

TL	*Type*	*Power*	*Price*	*Airframe*
4	Primitive Mechanical	—	.0001	Simple
5	Basic Mechanical	—	.0002	Fast Subsonic
6	Enhanced Mechanical	0.0002	.0003	Transonic
7	Electronic	0.0005	.0005	Hypersonic
8	Enhanced Electronic	0.0005	.00075	Hypersonic
9	Computer Linked	0.0005	.001	Hypersonic
10-12	Dynamic Linked	0.001	.0015	Hypersonic
13-16	Holographic Linked	0.001	.002	Hypersonic
17-20	Synaptic Linked	0.001	.0025	Hypersonic
21+	Synaptic Fluidic	0.001	.003	Hypersonic

Power: MW per displacement ton of the craft.

Price: MCr per displacement ton of the craft.

Airframe: Maximum airframe type that can be equipped with these controls (for use with aircraft design).

Volume and Mass: Control systems used in vehicles and spacecraft displace 0.014 cubic meters and mass 0.0014 tonnes per displacement ton of the hull.

Aircraft Controls: The values on the Controls table are for spacecraft and vehicles, whose size are calculated in terms of volume. As aircraft calculate size in terms of weight, some modification is necessary. All controls mass 0.014 tonnes per tonne of overall weight of the aircraft. Multiply the power and prices above by 10, and apply them per tonne of overall aircraft weight.

RCV Controls: Vehicles and spacecraft may be designed to function without on-board crews. Such craft require controls, avionics, and sensors, but do not require life support or computers. Vehicles intended specifically for RCV operations are typically reconnaissance vehicles or military vehicles used in very high-threat environments.

Remotely commanded vehicle (RCV) controls may be installed on any aircraft, vehicle, or spacecraft. In the case of aircraft and spacecraft, the RCV option adds 10% to the mass, volume, and price of the controls. In the case of a vehicle, it adds 1% to the mass, volume, and price of the suspension.

RCV controls require a sensor (usually a video camera) in the vehicle and a communication link between the vehicle and the operator. A simple video camera (available at tech level 6 and beyond) masses 2 kilograms, displaces 3 liters (allowing for traverse) and costs Cr100. Communicators are selected from those available in the Electronics chapter.

A number of RCV operators are required equal to the number that the RCV would require if it were manned. (A simple spaceborne sensor drone only requires one operator, as coasting through space does not require the attention of a pilot the way an atmospheric craft does.) Each operator requires a workstation or crewstation (according to where the operators are located, i.e., in a vehicle, aircraft, or spacecraft; ground stations, which have lots of space, are treated as spacecraft and therefore use workstations) of a tech level equal to that of the RCV.

For truly ambitious RCV operations, in which a large, normally manned vehicle or spacecraft is converted to RCV operations, each workstation or crewstation that is to function in the remote operations must additionally have its mass, volume, and price increased by 10%. A number of RCV controllers equal to the normal crew are required to operate it. Each RCV operator requires a workstation or crewstation identical to the one on the vehicle that it is remotely controlling.

In addition, any RCV that would normally (i.e., if it were manned) require one or more computers must have the appropriate number and type of computers installed with the workstations of its operators.

For spaceborne RCV operations, the time lag inherent when RCV and operators are separated by a light-second or more create difficulties (increase the difficulty of all tasks by one level for each light-second apart). Operators of spaceborne sensor drones are therefore often equipped with MFDs to assist with these difficulties. In order to use the MFD's ability to ignore Diff Mods, the RCV must be within the MFD's extreme range (8×short range listed on the MFD table), so the designer must choose the range of such an MFD accordingly.

WORKSTATIONS AND CREWSTATIONS

Vehicles, aircraft, spacecraft, and many weapons require the allocation of workstations or crewstations to allow crewmembers to control important equipment or machinery. Workstations are used on spacecraft and very large vehicles which perform missions lasting days or more. Crewstations are used on aircraft and vehicles which are typically operated for 24 hours or less at a time.

These are each of two types: normal workstations and roomier bridge workstations, and cramped crewstations and roomier open crewstations. The only difference between these is their volumes. Guidelines for the use of the different types of stations are provided in the vehicle design sequences.

The tech level of workstations/crewstations installed must be the same as the installed controls.

WORKSTATIONS AND CREWSTATIONS

TL	*Bridge W/S Vol*	*Normal W/S Vol*	*Crewstation Crmp/Open*	*Mass*	*MCr*
4	—	—	2.5/3.5	0.1	0.0001
5	—	—	2.5/3.5	0.1	0.0002
6	—	—	2.5/3.5	0.2	0.0003
7	14	7	2.5/3.5	0.2	0.0005
8	14	7	2.5/3.5	0.2	0.00075
9	14	7	2.5/3.5	0.2	0.001
10-12	14	7	2.5/3.5	0.2	0.0015
13-16	14	7	2.5/3.5	0.2	0.002
17-20	14	7	2.5/3.5	0.2	0.0025
21+	14	7	2.5/3.5	0.2	0.003

Volume: In cubic meters. Under Crewstation, Crmp indicates the volume of a cramped crewstation, Open indicates the volume for an open crewstation.

Mass: In tonnes

MCr: Price in megacredits (millions of credits)

W/S: Workstation

NAVIGATIONAL AIDS

Flight avionics assist spacecraft and aircraft in maneuvering over the ground and making takeoffs and landings, particularly in difficult circumstances (such as night or inclement weather). Terrain following avionics assist lift vehicles, large lift craft (such as spacecraft with G-lifters), helicopters, and VTOL aircraft to fly at high speeds at nap-of-the-earth altitude. Navigation aids assist vehicles in navigating across the surface of world.

Flight Avionics

TL	*MCr*	*Vol*	*Mass*	*MW*	*Description*
4	.001	.0001	.0001	—	Magnetic compass
5	.01	.0001	.0001	—	Gyrocompass, barometric altimeter
6	.05	.0001	.0001	.01	Radar altimeter, transponder
7	.10	.001	.001	.1	Weather radar, FLIR, inertial positioning
8	.20	.001	.001	.1	Imaging radar
10	.25	.001	.001	.1	Imaging EMS, inertial/gravitational positioning

MCr: Price in MCr. If at any tech level higher than the level of introduction, price × 0.1; **Vol:** Displacement in cubic meters; **Mass:** Mass in metric tonnes; **MW:** Power requirement in MW; **Description:** TL 6 or better flight avionics necessary for a starship to land on the surface of a planet. Each level of avionics includes all features shown at lower tech levels as well. FLIR = forward-looking infrared, a focused high-resolution thermal-imaging device.

Terrain-Following Avionics

TL/Type	*Vol*	*Mass*	*MCr*	*NOE*
None	—	—	—	40
8	0.2	0.05	0.010	120

20	0.01	0.05	0.024	400
21	0.01	0.05	0.028	450

Vol: Volume in cubic meters (kiloliters); **Mass:** Mass in metric tonnes; **MCr:** Price in millions of credits; **NOE:** Safe nape of the earth (NOE) speed in kilometers per hour; **Power:** Power requirement, in MW is equal to Wt; **Antenna:** Antenna area, in square meters, is equal to Wt × 10.

Navigation Aids

TL	*MCr*	*Vol*	*Mass*	*MW*	*Description*
2	.001	.0001	.0001	—	Magnetic compass
5	.001	.0001	.0001	—	Gyrocompass
6	.001	.0001	.0001	.01	Transponder
7	.010	.001	.001	.01	Inertial positioning
8	.020	.001	.001	.01	Satellite positioning
10	.025	.001	.001	.01	Integrates IGS positioning

MCr: Price in MCr. If at any tech level higher than level of introduction, price × 0.1; **Vol:** Displacement in cubic meters; **Mass:** Mass in metric tonnes; **MW:** Power requirement in MW; **IGS:** Inertial gravitational satellite

COMPUTERS

If a computer is desired, select one from the list below. Any orbital or deep-space craft must have at least one computer, and jump-capable craft require an additional computer. Space craft may use either standard or fiber-optic models of computers, or a mix of the two.

Spacecraft generally have at least two computers: one is the primary, the other is a dedicated maintenance troubleshooter and safety backup; starships have three: one primary, one for jump capability/backup, and another for maintenance troubleshooting, which also functions as a backup.

Aircraft with computers may use flight computers (Model Flt). Hypersonic aircraft should have two computers (but are only required to have one); one is a safety backup. Supersonic and slower aircraft are not required to have computers, but may choose to do so to help with long-range sensors and weapons operations.

Important Note: A computer may not be installed which is from a different tech level than the craft's control system. A craft may not have installed sensors or master fire directors from tech levels higher than the installed computer or control system. St or Fb computers are required for any craft fitted with an MFD, or a sensor with a short range greater than 30 kilometers. (Sensors with a short range of 30 kilometers or less do not require a computer.)

Computers Table

TL	*Mod*	*MW*	*Vol*	*Mass*	*MCr*	*Mult*
5	St	0.50	50	10	1.5	1
6	St	0.10	10	2	1.0	0.8
7	St	0.15	5	1	0.5	0.7
8	St	0.20	5	1	0.4	0.6
9	St	0.25	5	1	0.6	0.5
10	St	0.30	6	1.2	1	0.45
11	St	0.35	7	1.4	2	0.4
12	St	0.40	8	1.6	3	0.35
13	St	0.45	9	1.8	4	0.3
14	St	0.50	8	1.6	5	0.25
15	St	0.55	7	1.4	6	0.2
16	St	0.60	6	1.2	10	0.15
17	St	0.60	5	1	11	0.13
18	St	0.60	4	0.8	12	0.11
19	St	0.55	3	0.6	13	0.09
20	St	0.50	2	0.4	14	0.07
21	St	0.45	1	0.2	15	0.05

TL: Tech level of availability.

Mod: Model St = Standard, Fb = Fiber-optic, Flt = flight.

Fiber-optic computers are available from TL 7 on. Multiply MW, volume, mass, and price by 2. Usually one or more of a starship's three computers are fiber-optic.

Flight computers are simplified versions of the above computers optimized to perform a set number of routine flight functions. They may be used in place of standard computers on atmospheric and sub-orbital craft, although full-size computers may be installed as well. Flt computers do not provide maintenance point reduction. Multiply volume, MW, and mass by 0.1 and price by 0.001.

MW: Power requirement in MW

Vol: Displacement in cubic meters

Mass: Mass in metric tonnes

MCr: Price in millions of credits

Mult: Control multiplier

CHAPTER 5
Electronics

Electronics fall into three categories: communicators, sensors, and electronic countermeasures (ECM). The technologies discussed below in each of these categories are those available in the Imperial Space campaign universe. The fourth section in this chapter deals with alternative technologies, most of which are used in conjunction with alternative FTL drives.

Electronics Pods: Any of the electronic systems listed below may be placed in streamlined pods for mounting on hardpoints on aircraft and lift vehicles. Each pod has a shell weight equal to 10% of its final weight. Each pod can mount an antenna with an antenna area equal to 1 square meter per 1000 kilograms (1 metric tonne) of total pod weight.

For all electronic systems which do not calculate antenna price separately, antenna price is equal to 0.25 times the total system cost, for purposes of replacing destroyed antennae.

A. COMMUNICATORS

Communicators can be either broadcast or tight beam. Radio is the principal form of broadcast communications while laser, maser, and meson communicators are tight beam. Tight beam communicators are much more difficult to intercept or jam, but are also somewhat more complex and require that the transmitter know the precise location of the receiver.

Laser Communicators

			Volume at Tech Level						
Range	*MCr*	*MW*	*8*	*9*	*10*	*12*	*15*	*18*	*20*
3	.0012	.005	.004	.002	.001	.001	—	—	—
30	.005	.01	.016	.008	.006	.004	.001	—	—
300	.011	.02	.020	.010	.008	.005	.002	—	—
3000	.021	.04	.040	.020	.015	.010	.003	.001	—
30,000	.036	.08	.070	.035	.025	.018	.005	.002	.001
300,000	.056	.15	.110	.055	.040	.028	.007	.003	.002
1000 AU	.180	.3	—	.120	.070	.050	.015	.007	.005

Range: Short range in kilometers (or Astronomical Units, as indicated by the abbreviation AU)

Range Note: Maximum range in an atmosphere coded Thin or greater is 5000 km

Volume: Cubic meters (kiloliters)

MCr: Price in millions of credits

MW: Power requirement in megawatts

Mass: Mass, in metric tonnes, equals volume × 2

Antenna: Antenna area equals 1 square meter for all versions

Radio Receivers

All spacecraft are automatically equipped with radio receivers integral to their hulls at no additional cost. These allow radio reception and are destroyed by electronics hits (1h).

Vehicles of TL 8+ have the same integral radio receivers at no cost. At lower tech levels, vehicles may add radio receivers at no volume at MCr0.0001.

There is no power requirement for any of these receivers.

Finally (in the event that these receivers are destroyed in combat), all passive EMS sensors function as radio receivers, even, in the case of folding arrays, when retracted.

Maser Communicators

			Volume at Tech Level						
Range	*MCr*	*MW*	*8*	*9*	*10*	*12*	*15*	*18*	*20*

Range: Short range in kilometers (or Astronomical Units, as indicated by the abbreviation AU); **Volume:** Cubic meters (kiloliters); **Price:** Price in MCr. If TL 5, ×3. If TL 6, ×2; **MW:** Power requirement, in megawatts; **Mass:** Mass, in metric tonnes, equals volume × 2; **Antenna:** Antenna area, in square meters, equals MW × 10.

B. SENSORS

Sensors detect the presence of targets either by detecting energy emitted by the target or by reflecting energy off of them and detecting the reflection. The first type of sensor is known as a passive sensor, since it does not emit energy of its own. The second type is called an active sensor, since it projects energy and bounces it off the target. Radar, ladar, and active EMS are all active sensors, while passive EMS, high-resolution thermal, densitometers, neutrino sensors, and neural activity sensors are passive.

Aside from signal power, there are two critical issues in sensor design: antenna size and detector element size.

Antenna size is important for two reasons.

First, the absolute size (surface area) of an antenna determines the amount of energy it can collect. The larger a sensor, the more energy that can be collected from a faint target, thus the more sensitive the sensor is. At higher tech levels, the detection elements on the sensor's surface become more sensitive, allowing the absolute size of the sensor to decline with no diminution of sensitivity.

Second, the diameter of a sensor determines its *resolution*, or ability to see detail by separating closely spaced objects into discrete images. Resolution is expressed as the linear dimension that can be resolved, and varies with the wavelength of radiation coming from the target (i.e., short wavelengths allow finer resolution, hence greater detail), but varies inversely with sensor diameter. Thus, very high diameters are required to get good resolution in the infrared wavelengths that are so useful in space combat. This is limited by physics, not technology.

Because most ships cannot carry around huge 800-meter diameter dishes, some way must be found to decouple surface area from diameter. This method is called *aperture synthesis*, in which the effect of a large diameter dish is created by the use of one or more smaller dishes. The way that this is done for spacecraft is to reduce the single large dish (or telescope, or whatever) into an array of several smaller dishes whose signals are processed and combined by a computer to create the effect of one single large dish. The resolution of a synthetic aperture array with a distance X between the outermost edges of its outermost dishes is identical to a single large dish with a diameter of X (although its potential sensitivity is greatly reduced). On starships, these dishes are mounted on folding struts that allow them to be extended out to the required distance. They can also be retracted for atmospheric entry, docking, etc., but cannot be used when retracted.

There is a slightly different use of the synthetic aperture concept that is used for active sensors on planetary vehicles, typically aircraft. Computerized processing allows a fast-moving vehicle to use its own speed to stretch its effective sensor diameter along its flight path. The radar emits pulses at a fixed angle from its flight path (called "staring," as opposed to "scanning" back and forth), and the computer electronically combines the sensor pulses returned during a period of flight time and integrates them into an image as detailed as if the sensor diameter was equal to the aircraft's speed times the period over which the pulses were built up. Naturally, flight must be straight and level to allow accurate computations, and this only works for targets away from the sensor platform's flight path, i.e., it cannot look directly ahead. A variation of this, *inverse synthetic aperture*, uses the target's relative motion, and allows the sensor to look straight ahead, although this has inherently less resolution than normal synthetic aperture systems.

However, this is only practical because of the relatively short ranges between planetary targets compared to the tremendous distances between space targets. In space, the relative speeds of sensor to target are insignificant compared to the distances involved. Only an absolute increase in effective array diameter can address these issues.

These antenna size issues affect all sensors, but are particularly important for passive sensors which must use the energy that is coming off the target. Active sensors pump energy at the target and listen for the echo, so they can make up for lack of antenna size by increasing radiated power, and by decreasing the wavelength of this power.

The second critical issue is detector element size. Each detector element in the receiver represents a fixed proportion of the total area scanned by the sensor. If the signal received from an object is a smaller proportion of the "picture" drawn by the sensor than one detector element, resolution is reduced to a blob with no detail.

Radar

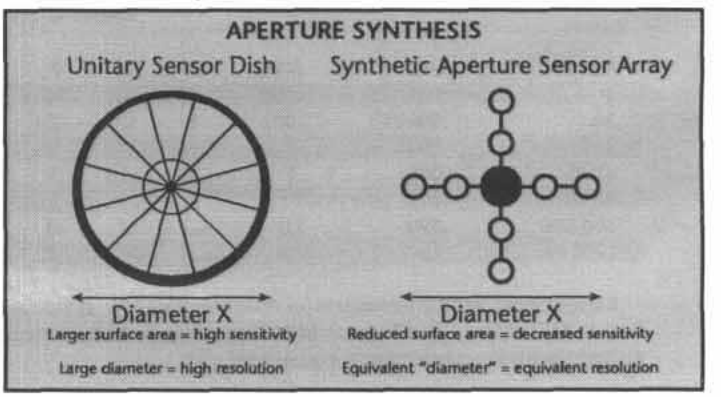
Radar is an active sensor which bounces radio waves off of targets and then detects the returning echoes. A radar requires a processor unit and an antenna.

	Processor Volume by Tech Level				
Short Range	*5*	*6*	*7*	*8*	*9*
0.3 km	0.3	0.1	0.04	0.02	0.01
3 km	3	1	0.4	0.2	0.1
30 km	30	10	4	2	1
300 km	300	100	40	20	10
3,000 km	—	—	400	30	15
30,000 km	—	—	—	40	20
60,000 km	—	—	—	50	30

Volume: Volume in cubic meters (kiloliters) as shown

MW: Power requirement (in megawatts) equals processor volume in cubic meters × 0.2

Mass: Mass of the processor, in tonnes, equals volume × 2



MCr: Price of the processor, in MCr, equals volume × 1

Antenna: Antenna area (in square meters) equals volume times the tech level modifier shown in the following table:

TL	*Modifier*
5	10
6	6
7	4
8	1
9+	0.5

Antenna Volume (cubic meters): Antenna area × 0.1

Antenna Mass (in metric tonnes): Antenna area × 0.1

Active EMS

Active EMS incorporates a variety of active emitters and passive detectors covering most of the electromagnetic spectrum (EMS), making it a much more sophisticated version of radar.

	Volume (kl) by Tech Level						
Short Range	*10*	*11*	*12*	*14*	*16*	*18*	*20*
3 km	0.2	0.1	0.1	0.1	0.1	0.1	0.1

300,000 km	26	12	5.5	3.0	2.0	1.5	1.0
360,000 km	31	15	7.0	3.4	2.2	1.7	1.1
420,000 km	36	17	8.5	4.2	2.4	1.8	1.2
480,000 km	42	20	10	5.0	2.6	1.9	1.3

Volume: Volume in cubic meters (kiloliters) as shown.
Power (MW): Volume × 5
Price (MCr): Volume × 2
Mass (tonnes): Volume × 2
Antenna (square meters): Volume × 2. Antenna volume, mass, and price are subsumed in the total sensor package above.

Ladar

Ladar is a tight beam active sensor that bounces laser light off of the target and detects the reflection. As the laser can scan a very small area, it is used exclusively to lock onto a target after some other search sensor has detected it.

Range: Short range in kilometers
Power Requirement (MW): Volume in cubic meters
Mass (metric tonnes): Volume × 2
Price (MCr): Volume × 10
Antenna Area (square meters): Volume × 1. Antenna weight, price, and volume are subsumed in the above figures.

Densitometer (Grav Shielded)

Densitometers are survey instruments which allow determination of celestial object mass and mapping of mineral deposits and gravitic anomalies.

TL	*MW*	*Vol*	*Mass*	*MCr*
11	2.5	30	10	0.75
12	1	15	5	0.9
13	0.9	12	3	0.95
14	0.5	9	2	1
15	0.4	7	1.5	1.5
16	0.3	4	1	1.5
18	0.2	2	0.8	1.5
20	0.1	1	0.7	1.5

MW: Power requirement in megawatts.
Vol: Volume in cubic meters.
Mass: Mass in tonnes.
MCr: Price in millions of credits.
Antenna Area (square meters): MW × 100.

Neutrino Sensor

Neutrino sensors are useful when surveying a star system. They enable a ship to measure the intensity of fusion taking place within a star as well as determine if any of the gas giants are failed stars.

TL	*Vol*	*MCr*
10	100	1
12	10	2
14	5	3
16	2	4
18	1	5

Vol: Volume in cubic meters.
MCr: Price in millions of credits.
MW: All neutrino sensors require 0.01 MW of power for operation.
Mass: All neutrino sensors have a mass in tonnes equal to their volume.
Neutrino sensors have no antennae.

Neural Activity Sensor

Neural activity sensors detect and classify life forms according to their level of brain activity.

TL	*Range*	*MW*	*Vol*	*Mass*	*MCr*
13	0.005	0.004	0.002	0.005	0.02
14	0.025	0.005	0.002	0.005	0.02

Range: Short range in kilometers.
MW: Power requirement in megawatts.
Vol: Volume in cubic meters.
Mass: Mass in tonnes.
MCr: Price in millions of credits.
Antenna Area (square meters) = MW × 100.

High-Resolution Thermal (HRT)

HRT sensors are sophisticated visual sensors sensitive to infrared radiation.

			Volume by Tech Level		
Range	*AD*	*AA*	*7*	*8*	*9*
0.3	0.25	0.05	0.006	0.003	0.001

30	.1	1	0.3	0.15	0.05
300	2.25	4	0.6	0.3	0.1
3000	3.5	10	1.5	0.6	0.3
30,000	5	20	—	1.5	0.6
60,000	10	80	—	3	1.5
90,000	20	300	—	5	2.5
120,000	40	1200	—	6	3
150,000	90	6000	—	7	3.5
180,000	200	30,000	—	8	4
210,000	400	125,000	—	9	4.5
240,000	800	500,000	—	10	5

Range: Short range (in kilometers)

AD: Antenna diameter, in meters. If the antenna diameter is greater than the hull length (unmodified by configuration), the antenna must be a folding array.

AA: Surface area of the antenna is square meters. At tech level 9, multiply antenna area by 0.5.

Volume: The volume of the processor in cubic meters (kiloliters) as shown on the table.

Antenna Volume: The volume of the antenna in cubic meters (kiloliters) is equal to the antenna area × 0.05 for a fixed array or × 0.1 for a folding array.

MW: Power requirement, in megawatts, is equal to the processor volume × 0.1.

Processor Price: The processor price, in millions of credits, is equal to the processor volume × 1.

Antenna Price: The antenna price, in millions of credits, is equal to the antenna volume × 1.

Processor Mass: The mass of the processor, in tonnes, is equal to the processor volume × 2.

Antenna Mass: The mass of the antenna, in tonnes, is equal to the antenna volume × 1.

Visible and Infrared Light Sensors

These sensors use visible or infrared light to detect an object, either relying on background light (passive) or illuminating it with a beam of light (active). Due to the short range of these sensors, they are usually used on vehicles rather than spacecraft. (AIR = active infrared; PIR = passive infrared; LA = light amplification; IE = image enhancement; WSV = wide-spectrum visual)

SENSORS

TL	*Description*	*MW*	*Vol*	*Mass*	*MCr*	*Range*

12	WSV Goggles	.0001	—	.0001	.00500	.3

Volume in cubic meters, Mass in tonnes, Range indicates short range in kilometers. Asset is Observation for goggles, scopes, and head/searchlight, Sensors for viewers and radar.

Passive EMS

Passive EMS uses large antenna arrays to detect any electromagnetic emanations from a potential target, such as heat or radio waves, or naturally reflected light waves. It is an extremely sophisticated and precise sensor.

			Volume by Tech Level						
Range	*AD*	*AA*	*10*	*11*	*12*	*14*	*16*	*18*	*20*
3	.25	.02	.03	.02	.01	.005	.003	.002	.001
30	.5	.08	.1	.08	.04	.02	.01	.005	.002
300	1	.4	.2	.1	.08	.04	.02	.01	.005
3,000	2.25	1.6	.3	.2	.1	.08	.04	.02	.01
30,000	3.5	4	.6	.4	.3	.2	.1	.08	.04
60,000	5	8	1.5	1	.6	.4	.3	.2	.1

120,000	20	120	2.5	2	1.5	1	.6	.4	.3
150,000	40	480	3	2.5	2	1.5	1	.6	.4
180,000	90	2400	3.5	3	2.5	2	1.5	1	.6
210,000	200	12,000	4	3.5	3	2.5	2	1.5	1
240,000	400	50,000	4.5	4	3.5	3	2.5	2	1.5

Range: Short range (in kilometers).

Volume: The volume of the processor in cubic meters (kiloliters) as shown on the table.

AD: Antenna diameter, in meters. If the antenna diameter is greater than the hull length (unmodified by configuration), the antenna must be a folding array.

AA: Base surface area of the antenna in square meters. The actual surface area of the antenna is this value multiplied by a tech level modifier, as shown below:

TL	*Modifier*
10	1
11	0.5
12	0.25
13	0.125
14	0.075
15	0.025
16+	0.01

Antenna Volume: The volume of the antenna in cubic meters (kiloliters) is equal to the antenna area × 0.05 for a fixed array or × 0.1 for a folding array.

MW: Power requirement, in MW, is equal to the processor volume × 0.1.

Processor Price: The processor price, in millions of credits, is equal to the processor volume × 2.

Antenna Price: The antenna price, in millions of credits, is equal to the antenna volume × 1.

Processor Mass: The mass of the processor, in tonnes, is equal to the processor volume × 2.

Antenna Mass: The mass of the antenna, in tonnes, is equal to the antenna volume × 1.

C. ELECTRONIC COUNTERMEASURES (ECM)

Also known as electronic warfare (EW) equipment, ECM is designed to combat enemy sensors and communicators by either disrupting their operation or locating them with an eye toward their destruction.

Radio, Radar, and EMS Jammers

Radio, radar, and EMS jammers have the same characteristics as radios, radars, and active EMS sensors, with three exceptions.

1. Power use and price are multiplied by 2.
2. Antenna size for the radar jammer is divided by 10.
3. Jammers may not be used as sensors or communicators, only for jamming.

Radio jammers may only be used to jam radios; radar jammers may be used to jam radar or active EMS; and EMS jammers may be used to jam radios, radars, or active EMS.

Area Jammers

Area jammers degrade the effectiveness of sensors and communicators that attempt to function in their area of effect. The principal design decision, therefore, is the area of effect of the jammer, all other values being derived from that. The area of effect is defined as the radius of effect in kilometers. (Note that space-based area jammers routinely have an effect radius of 45,000 kilometers.)

TL	*MW*	*Vol*
10	.002	.32
11	.001	.30
12	.00045	.40
14	.00036	.375
16	.00027	.42
18	.00018	.375
20	.00009	.40

TL: Tech level of first availability.

MW: Power requirement, in megawatts, per kilometer of effect radius.

Vol: Volume, in cubic meters, per megawatt of power.

Mass: The mass of an area jammer, in tonnes, is equal to its volume in cubic meters.

Price: The price of an area jammer, in millions of credits, is equal to its volume in cubic meters multiplied by 2.

Sensor Decoys

These require no power and instead are dispensors for decoy material, consisting of flares intended to duplicate the heat signature of the craft, metallic strips, sometimes self-inflating, which mimic the reflected signature of the craft, or anti-laser aerosols to disperse the laser light and prevent it from providing a precise reflection.

Decoys work on ladar (anti-laser aerosols), active radar or EMS (metallic chaff), or passive infrared such as HRT or passive EMS (heat flares). Designers may include different types of decoys on a craft, but each type only works on the specified sensor. A decoy increases the difficulty of a target lock by 1 if of an equal tech level with respect to the sensor and increases it by 2 if from a higher tech level.

The required size of a decoy is 0.002 cubic meters for Sub-Micro size craft. This increases by 0.001 cubic meters per increase in target size, so that a Very Small target requires 0.004 cubic meters per decoy.

All decoys mass 0.5 metric tonnes per cubic meter and cost MCr5 per m^3.

Decoys are usually carried in internal automatic dispensers, but aircraft may also carry them using the electronic pods rule at the beginning of this chapter (page 49). They are dispensed one at a time, but a dispenser may launch one decoy per second. More than one decoy does not further decrease the chance of sensor locks.

When used with planetary combat, each decoy lasts one combat turn, and affects all sensor attempts against the owning vehicle, regardless of direction.

When used with **Brilliant Lances**, decoys are "popped" at the end of the Movement Phase, after all movement has been completed. In order to cover the ship as it moves throughout the turn, one decoy must be popped per G-turn expended that turn (0 G-turns expended still requires one decoy) for maneuver, and two per G-turn spent for evasion. This full amount constitutes one "salvo." Each decoy salvo only affects sensors coming in through a single hexside (this includes sensor attempts which are traced across either adjoining hex vertex), but affects all sensor scans made from that direction for the entire turn. Thus, a ship which expended 4 G-turns for maneuver must pop 4 decoys to get protection across one hexside for a turn, 24 decoys to get 360° protection for that turn, or 48 decoys for 360° coverage if it spent 4 G-turns on evasion.

Decoy dispensers are hit by surface hits. They have a surface area of 1 m^2 and have their hit capacities calculated on their loaded mass. Dispenser volume is equal to 2 times the volume of the decoys it holds, mass is 1 tonne per cubic meter, and cost is MCr0.001 per cubic meter.

Radio, Radar, and EMS Direction Finder

Direction-finding can be added as an option to any radar or active EMS array. (Passive EMS arrays already incorporate radio and radar DF capabilities.) Price is multiplied by 2 for radar, and by 1.5 for the EMS array. Stand-alone direction finders are also available beginning at TL 6. These have the same mass, volume, and antenna size of a radio of the same tech level, but the price is doubled, and the power requirement in MW is equal to the volume at all ranges and tech levels. All direction finders work equally well versus radio, radar, or EMS emissions.

Stealth

Stealth design minimizes a craft's electromagnetic emissions in the most common bands (radio and IR), and uses electromagnetic absorbent material (EMAM) on the hull surface, thus making detection by active and passive sensors (radar and HRT) more difficult.

Stealth design increases the difficulty of an HRT or radar lock on it by one difficulty level (two if from a higher tech level than the sensor), but has no effect on other types of sensors.

Stealth aircraft may not have turrets, hardpoints, or any other feature which produces a drag point. Hypersonic airframes may not incorporate stealth design.

Stealth design is available at TL 8 and higher. The following values are per displacement ton (14 cubic meters) of hull. When applying stealth to aircraft, multiply aircraft mass by 5 to determine effective displacement for purposes of EMM. (Note that this is *not* the same displacement used to calculate the storage volume of the craft.)

Volume (m^3)	*Mass (tonnes)*	*Price (MCr)*
0.5	0.1	0.05

Electromagnetic Masking (EMM)

Electromagnetic masking is an advanced form of stealth design, and includes radiators to dissipate immense IR signatures as well as more advanced electromagnetic absorbing material. EMM packages may not be installed in addition to stealth, but rather are used in place of it. EMM effects are +2 Diff Mods vs. HRT or radar, and +1 Diff Mods vs. passive or active EMS sensors.

Unlike stealth design, EMM may be used on hypersonic airframes, and aircraft may carry hardpoint ordnance or other drag-producing features. However, EMM's effect on detection difficulty is reduced by one level if a hypersonic airframe is used, by one level if any drag-producing features are incorporated in the design, and thus is reduced by two levels if both effects are present. (Note, however, that an aircraft whose only drag-producing feature was hardpoint stores could gain back its +1 modifier by dropping its stores.)

EMM packages are available at TL 10 and higher. The following values are per displacement ton (14 cubic meters) of hull. When applying EMM to aircraft, multiply aircraft mass by 5 to determine effective displacement for purposes of EMM. (Note that this is *not* the same displacement used to calculate the storage volume of the craft.)

Power (MW)	*Vol (m^3)*	*Mass (tonnes)*	*Rad*	*Price (MCr)*
0.014	0.28	0.14	0.14	0.07

Rad: Hull area used by IR radiators (in square meters).

D. ALTERNATE TECHNOLOGY

The following electronic devices rely on FTL drive technologies other than the J-space rationale of the Imperial Space campaign.

Subspace Radio

Subspace is explained in the alternate technology section of the FTL Drive chapter (Section 3). Since subspace consists of a resisting medium, it is possible to propagate waves through it and thus achieve FTL communication. Waves travel through the subspace medium at a constant velocity of 1 (N-space) parsec per hour, which imposes a time lag on subspace radio communication.

Subspace radios consist of separate transmitters and receivers. While transmitters are often quite bulky and their power requirements are based on their range, receivers are comparatively simple and can pick up a signal at any range (provided it is from a transmitter capable of sending at that range).

SUBSPACE TRANSMITTER

			Volume at Tech Level							
Range	*MCr*	*MW*	*9*	*10*	*11*	*12*	*14*	*16*	*18*	*20+*
1	0.075	1	5	1	.1	.01	.01	.01	.001	.001
2	0.25	2	10	5	1	.1	.01	.01	.01	.001
3	0.5	3	15	10	5	1	.1	.01	.01	.01
4	1	4	30	15	10	5	1	.1	.01	.01
5	3	5	70	30	15	10	5	1	.1	.01
10	9	10	—	70	30	15	10	5	1	.1
20	15	20	—	—	70	30	15	10	5	5

Range: Short range in parsecs.
Volume: Cubic meters (kiloliters).
MCr: Price in MCr.
MW: Power requirement, in megawatts.
Mass: Mass, in tonnes, equals volume × 2.
Antenna: Antenna area, in square meters, equals volume in cubic meters × 10.

SUBSPACE RECEIVER

TL	*Volume*
9	2
10	1.5
11	1
12	0.8
13	0.6
14	0.4
15	0.2
16	0.1
17	0.05
18	0.01
19	0.005
20+	0.001

TL: Tech level of availability.
Volume: Cubic meters (kiloliters), including antenna.
Price: Price for a subspace receiver is MCr0.05 at tech level 9 and MCr0.01 at all higher tech levels.
MW: Power requirement is 0.001 megawatts at all tech levels.
Mass: Mass, in tonnes, equals volume in cubic meters.

Subspace Active Sensor (SAS)

Just as waves propagated through subspace can be used to communicate, wave echoes can be used to detect objects in subspace in the same manner as radar or sonar. An active subspace sensor array requires a processor unit and an antenna.

	Processor Volume by Tech Level								
Range	*9*	*10*	*11*	*12*	*13*	*14*	*15*	*16*	*18+*
0.01	10	5	2	1	.5	.4	.3	.2	.1
0.02	30	10	4	2	1	.5	.4	.3	.2
0.03	300	100	40	20	10	4	2	1	.5
0.04	—	—	200	30	15	8	4	2	1
0.05	—	—	—	40	20	15	8	4	2
0.06	—	—	—	50	30	20	15	8	4

Range: Short range in parsecs.
Volume: Volume in cubic meters (kiloliters) as shown.
MW: Power requirement (in megawatts) equals processor volume in cubic meters × 0.2.
Mass: Mass of the processor, in tonnes, equals volume × 2.
MCr: Price of the processor, in MCr, equals volume × 1
Antenna: Antenna area (in square meters) equals volume times the tech level modifier shown below:

TL	*Modifier*
9	8
10	6
11	4
12	2
14	1
16+	0.5

Antenna Volume (cubic meters): Antenna area × 0.1
Antenna Mass (in tonnes): Antenna area × 0.1
Antenna Price (MCr): Antenna area × 0.05

Passive Subspace Sensor (PASS)

Subspace radio and active sensor waves may be detected by passive sensors, as may the subspace *"wake" of a starship.* PASS arrays do not require a great deal of power, but do require extremely sensitive antennae and sophisticated processor units.

PASS arrays can locate the sources of subspace radio or active sensors emissions well enough to provide target solutions, and so are useful combat sensors. Subspace wake sensing cannot detect the approach of a vessel, and so is not useful in combat. Instead the wake-sensing capability of PASS arrays is used as a means of tracking ships through subspace.

PASS arrays consist of a processor and an antenna.

PASS Processor Volume by Tech Level

Range	*AD*	*AA*	*9*	*10*	*12*	*14*	*16*	*18*	*20+*
0.01	0.5	0.08	1	0.8	0.4	0.2	0.1	0.06	0.04
0.02	1	0.4	2	1	0.8	0.4	0.2	0.1	0.06
0.03	2.25	1.6	3	2	1	0.8	0.4	0.2	0.1
0.04	3.5	4	6	4	3	2	1	0.8	0.4
0.05	5	8	15	10	6	4	3	2	1
0.06	10	32	20	15	10	6	4	3	2
0.07	20	120	25	20	15	10	6	4	3
0.08	40	480	30	25	20	15	10	6	4
0.1	90	2400	35	30	25	20	15	10	6
0.2	200	12,000	40	35	30	25	20	15	10
0.4	400	50,000	45	40	35	30	25	20	15

Range: Short range (in parsecs).

Processor Volume: The volume of the processor in cubic meters (kiloliters) as shown on the table.

AD: Antenna diameter, in meters. If the antenna diameter is greater than the hull length (unmodified by configuration), the antenna must be a folding array.

AA: Base surface area of the antenna in square meters. The actual surface area of the antenna is this value multiplied by a tech level modifier, as shown below:

TL	*Modifier*
9	1
10	0.5
12	0.25
14	0.125
16	0.075
18	0.025
20+	0.01

Antenna Volume: The volume of the antenna in cubic meters (kiloliters) is equal to the antenna area × 0.05 for a fixed array or × 0.1 for a folding array.

MW: Power requirement, in MW, is equal to the processor volume × 0.1.

Processor Price: The processor price, in millions of credits, is equal to the processor volume × 2.

Antenna Price: The antenna price, in millions of credits, is equal to the antenna volume × 1.

Processor Mass: *The mass of the processor, in metric* tonnes, is equal to the processor volume × 2.

Antenna Mass: The mass of the antenna, in metric tonnes, is equal to the antenna volume × 1.

Subspace Direction Finders

Direction-finding can be added as an option to any subspace active sensor (SAS) array. (PASS arrays already incorporate DF capabilities.) Price is multiplied by 1.5 for the SAS array.

Stand-alone direction finders are also available beginning at TL 10. These have the same mass and volume of a subspace radio receiver of the same tech level, but the price is doubled, and the power requirement in MW is equal to 0.01 for all versions. All direction finders work equally well versus subspace radio and SAS emissions.

Subspace Jammers

Subspace radio and subspace sensor jammers have the same characteristics as subspace radios and SAS arrays, with three exceptions.

1. Power use and price are multiplied by 2.
2. Antenna size for the sensor jammer is divided by 10.
3. Jammers may not be used as sensors or communicators, only for jamming.

Radio jammers may only be used to jam radios; sensor jammers may be used to jam SAS and PASS arrays.

Tachyons

Tachyons are conceptual particles which travel faster than the speed of light. The term "conceptual" is used advisedly. Tachyons were conceived of, not discovered, as an interesting thought exercise in theoretical physics. What would the properties be, it was queried, of a particle which existed only while travelling faster than light?

Although there is no evidence that such a particle could actually exist (and overwhelming evidence that it does not), it has nevertheless found its way into science-fiction literature, and the same thought exercise leads authors to ask, "what if?" Nevertheless, tachyons should be approached with extreme caution if a hard science game is being played. They, like the Dean Drive (see the Lifters chapter, Section 10) are more at home with science fantasy than science fiction.

Tachyons allow FTL radio and active sensors, generally called "T-band" electronics. The same tables are used as for subspace radio, SAS arrays, ECM, and jammers, but the T-band waves move through N-space, not subspace.

Note that T-band communicators and sensors, alone among the alternate electronics technologies, do not have an associated FTL drive.

CHAPTER 6
Defensive Systems

Defensive systems refer to advanced technology methods of defeating attacks, methods which go beyond simply making armor thicker and harder.

EXPLOSIVE REACTIVE ARMOR (ERA)

Reactive armor is available at tech level 7 and beyond, and is a cheap alternative to composite and composite laminate armor. Reactive armor consists of a series of blocks of explosive material sandwiched between two metal plates. When a hollow charge (HEAP) warhead penetrates the outer metallic plate and contacts the explosive block behind it, the explosive detonates and blows the front metallic plate away from the vehicle. As the blocks are placed at an angle off of vertical, the plate blows off at an angle as well, removing part of the penetrator stream from the HEAP round. (See the Munitions chapter, beginning on page 135, for a discussion of how HEAP rounds penetrate armor.) This reduces the penetration of the HEAP penetrator jet considerably.

However, reactive armor has no effect on conventional solid penetrators, as the force of the explosion is insufficient to break up the penetrator rod, and so does not reduce either the mass or the velocity of the penetrator. Likewise, reactive armor has no effect on lasers, particle accelerators, or meson guns, but does affect plasma and fusion guns in the same way as it affects HEAP rounds.

Detonation: If the explosive reactive armor (ERA) array of a vehicle is hit by any round with a penetration of 10 or greater, the array detonates. From then on, one-twentieth of the ERA on that vehicle face is missing (having been exploded). Each time a round hits that vehicle side after that, roll 1D20. If the number rolled is equal to or less than the number of times the armor has detonated on that face, the round hits bare armor; if it is greater than that number, the round hits an intact part of the ERA.

For example, a tank is hit in the front by a round capable of detonating its ERA, and so one-twentieth of its ERA detonates. A second round hits and the player owning the vehicle rolls a D20. If a 1 is rolled, the round hits bare armor, but a 7 is rolled, and so the round hits intact ERA and detonates another section. When the next round hits the front of the tank it will hit bare armor on a roll of 2 or less.

Armor Value: ERA never adds its AV unless it detonates, and it never adds its AV against anything other than a HEAP round or a plasma or fusion bolt. If the round is HEAP or a plasma or fusion bolt and the array detonates, the array adds its AV to that of the AV of the structural armor of the vehicle.

Multiple Detonations: Whenever an ERA block explodes there is a chance that there will be a chain reaction of additional multiple detonations. Each type of ERA has a detonation number listed on the chart below. Whenever an ERA detonates, roll 1D20. If the roll is equal to or less than the detonation number of the armor, there is a multiple detonation. If there is a multiple detonation, roll the D20 again and that number rolled is the number of additional hit locations cleared of armor.

For example, a tank with improved ERA (detonation number of 3) is hit for the first time by a plasma bolt on a face protected by ERA. The ERA detonates and adds its armor to the base armor for purposes of stopping penetration by the plasma bolt. However, the owner of the tank rolls a 2 for multiple detonations, and since this is less than the detonation number of 3, there is a chain reaction multiple detonation. The player rolls a D20 again and this time rolls a 12. Twelve additional hit locations are stripped of ERA by the blast, which means that the next time that face is hit by a round, it will hit bare armor on a roll of 13 or less and ERA on a roll of 14 or higher.

Multiple Layers: Up to three layers of ERA may be added to the outside of a vehicle, but each layer after the first adds only half of its AV to the vehicle. The multiple detonation value of the ERA is sum of the detonation values of all the layers.

For example, a vehicle with three layers of Improved ERA would have an AV of (16+8+8=) 32 in addition to its normal armor value, and would have a multiple detonation number of (3+3+3=) 9.

Volume: ERA is seldom applied to the entire surface of a vehicle, and instead is usually applies to only one or two faces. First decide which faces of the vehicle will be covered. Next determine the volume of adding 1 additional centimeter of armor on that face (from the Ground or Lift Vehicle Design chapters). The volume of a single layer of ERA in cubic meters is equal to the volume of 1 additional centimeter of armor on that vehicle face multiplied by 20.

Mass: ERA masses 4 tonnes per cubic meter of volume.

Price: The price of ERA, in millions of credits, is equal to the volume of the array in cubic meters multiplied by 0.007.

Replacement Blocks: ERA is usually custom-designed for each vehicle to fit the vehicle's unique configuration. Replacement blocks may be purchased, but are unique to each vehicle, and in fact each face of each vehicle. Each replacement block has volume, mass, and price equal to that of one complete layer for that face divided by 20, and can replace one layer from a single detonation on that face. Twenty replacement blocks are required to replace one full layer on that face after a complete detonation.

EXPLOSIVE REACTIVE ARMOR

TL	*Description*	*Det*	*AV*
7	Basic ERA	5	12
8	Improved ERA	3	16
9	Advanced ERA	1	20

TL: Tech level of first availability.
Det: Detonation number (per layer) of the ERA.
AV: Armor value added by the ERA when it detonates.

DAMPERS, SCREENS, AND THE STRONG AND WEAK FORCES

In ancient times, people often explained the physical world in terms of four universal elements: earth, air, fire, and water. Our modern understanding of physics revolves around four universal forces: electromagnetism, gravity, the strong, or nuclear, force, and the weak force (although it would now appear that the electromagnetic and weak forces are merely manifestations of the *electroweak* force, and that there is a *color* force underlying the strong—but **Traveller**'s mandate does not take us that far). The strong force is the force that holds the sub-atomic particles (protons and neutrons) of the atom's nucleus together, and the weak force is related to the decay of subatomic particles.

Manipulation of electromagnetism became possible at tech level 3, but control and manipulation of the other forces has proven more difficult to master. Much of the advances in technology postulated in **Traveller** result from an ability to manipulate the strong and weak forces, and this ability is most directly used in the design of nuclear dampers and meson screens.

Nuclear Dampers

The creation of nuclear dampers is allowed by the understanding and manipulation of the strong and weak forces which control the stability of atomic nuclei. Nuclear damper units create interference fields in these forces, resulting in strong positive and negative nodes where the wave patterns intersect and interact. At negative nodes the forces are reduced, and at positive nodes they are reinforced. By selectively projecting these nodes onto a material, the atomic nuclei can be made more or less stable, depending upon the needs of the user. For example, by projecting a strong force negative node, the nucleons (particles of the nucleus: protons and neutrons) are held together less powerfully, allowing nucleons to escape (at early tech levels this use is imprecise, creating random transmutations, at higher tech levels it allows more reliable transmutation, albeit very expensively) at low energy levels. On the other hand, nodes can be projected that "freeze" a radioactive nucleus by preventing its decay and eliminating dangerous radiation.

The latter effect allows the manufacture of damper boxes that permit the transport of radioactive material without the need for heavy shielding.

Nuclear damper screens are created by projecting these fields at a distance to inhibit the function of nuclear warheads. By sufficiently strengthening the strong force with a positive node, a nuclear damper can prevent fission chain reactions from beginning by eliminating the spontaneous fission in a supercritical mass that begins the chain reaction. The projection of negative nodes, causing the shed of nucleons, can be dangerous at early tech levels, as the release of low-energy neutrons initiates the fission of common nuclear warhead materials. However, at higher tech levels, the effect can cause large numbers of nuclei to dissociate so rapidly into non-fissile elements that there are insufficient nuclei to maintain a chain reaction. This is fortunate because it is also this effect of the screen that is necessary to inhibit fusion warheads. While early dampers inhibit fusion warheads by disabling their fission triggers, pure fusion can only be prevented by reducing the strong force that permits the fusion to occur.

Nuclear Damper Screens: Unlike most weapons, damper screens only have a single range. Targets within that range may be attacked and targets outside of that range may not. All attacks by nuclear dampers are Difficult tests for success, a successful attack rendering the warhead inert.

When designing a nuclear damper, the designer specifies the range of the weapon in kilometers. All other values are derived from the Nuclear Damper Design table below. Space-based nuclear dampers must have a range of 30,000 kilometers in order to successfully intercept in-coming missiles.

Nuclear dampers require a beam pointer with a short range equal to the damper's absolute range. They also require a normal workstation for local control (or they may be controlled by an MFD which may control a number of dampers equal to its Diff Mod rating—this rating only allows the MFD to control multiple dampers, but does not allow it to apply its Diff Mod negations to damper tasks). Dampers may also be fitted with sensors which allow them to make their own target locks if the vehicle's main sensors are knocked out.

Nuclear Damper Design

TL	*MW*	*Vol*	*MCr*
12	.00050	5	0.13
13	.00030	8	0.3
14	.00020	10	0.67
15	.00010	11	1.5
16	.00008	13	2
18	.00006	16	4
20	.00003	18	6

TL: Tech level of construction.

MW: Power, in megawatts, equals the range in kilometers multiplied by the value shown on the table.

Vol: The volume of the damper, in cubic meters, is equal to its power in megawatts multiplied by the value on the table.

MCr: The price of the damper, in millions of credits, is equal to the power in megawatts multiplied by the value on the table.

Mass: The mass of the damper, in metric tonnes, is equal to its volume in cubic meters.

Antenna Area: The antenna area of the damper, in square meters, is equal to its volume multiplied by 0.1.

Nuclear Damper Boxes: Nuclear damper boxes are used to transport radioactive materials safely. Damper boxes are available at tech levels 11 and higher. Damper box design depends on the capacity of the box, which is expressed in tonnes of fissionable material. All other values are derived from the capacity of the box, as indicated below.

Mass: The mass of the box, in metric tonnes, is equal to its capacity multiplied by 0.3.

Volume: The volume of the box is equal to its capacity multiplied by 1.2.

Price: The price of the box, in millions of credits, is equal to its capacity multiplied by 0.33 unless the capacity of the box is 1 tonne or greater, in which case the price is equal to the sum of 0.9 plus the product of the capacity of the box multiplied by 0.03. (MCr = 0.9 + [0.03×Cap])

Power: The power requirement of the box, in megawatts, is equal to its capacity in tonnes multiplied by 0.001.

Meson Screens

A meson screen is another application of the ability to manipulate the strong force, which is transmitted by mesons. A meson screen projects an energy field surrounding the screen generator which slows and prematurely detonates high-energy mesons. The designer specifies only the power requirement (in MW) of the meson screen; all other values are derived from the power requirement, tech level, and volume of protected space.

Vol: The meson screen generator's volume, in cubic meters equals MW × 20.

Mass: The meson screen generator's mass, in metric tonnes, equals Vol × 0.75.

AA: The meson screen generator's antenna area, in square meters, equals MW × 10.

MCr: The meson screen generator's price, in millions of credits, equals Vol × 0.1.

Performance: The meson screen generates a Protection Value for the target which is used against incoming meson guns. The Protection Value is derived by the following formula:

$$PV = TLM \times \sqrt{MW+TSM}$$

PV= Protection value
TLM = Tech level multiplier
TSM = Target size modifier

Tech Level Modifiers

TL	TLM
12	50
13	60
14	70
15	80
16	90
17	100
18	105
19	110
20	115
21	120

Target Size Modifiers

Size	TSM
Small or less	1
Medium	2
Large	4
Very Large	8
Gigantic	16

Each meson screen requires crew equal to the mass of the screen (in tonnes + 100, times the computer control multiplier (round to the nearest whole number, but must be at least 1). Each crewmember requires one normal workstation installed as part of the screen installation.

SANDCASTERS

All sandcaster turrets fit in the standard turret hardpoint socket. Each turret weighs 50 tonnes and requires 1MW of continuous power while in operation.

The table below lists the price of the turret in megacredits, the number of sand cannisters carried in the turret, and the beam reduction made per successful beam interception. Additional sand cannisters may be stored in cargo, but it takes one hour to resupply a turret. Individual sand cannisters have a volume of 0.5m³, mass 0.5 tonnes, and have a cost in credits as indicated on the table.

TL	MCr	Cannisters Carried	Beam Reduction	Cann Cr
8	0.6	16	1D6×5	400
9	0.65	18	1D6×5	400
10	0.7	20	1D10×5	600
11	0.75	24	1D10×5	600
12	0.8	30	1D10×5	600
13	0.85	35	2D6×5	800
14	0.9	40	2D6×5	800
15-16	1	50	2D10×5	1000
17-18	1.2	54	2D20×5	1500
19-20	1.4	58	2D20×5	1500
21	1.6	62	3D20×5	2000

Sandcasters fire cannisters of ablative crystals, commonly called "sand." Each sandcaster also contains a generator which creates a field used to manipulate the location and shape of the cloud of crystals. At early tech levels, these fields are electromagnetic, and require magnetic sand. More advanced systems supplement, then supplant, the magnetic manipulation with gravitic manipulation, which allows the use of more effective nonmagnetic crystals.

These clouds are placed in the path of incoming beam weapons, and the beams expend their energy burning through the cloud. The sandcaster operator uses integral laser warning sensors to detect fire control locks and anticipate incoming beam fire. Each successful sandcaster hit reduces the beam by the indicated amount, and requires that another cannister be expended to replace the burned sand.

ELECTROSTATIC ARMOR (ESA)

Electrostatic armor is, until the development of the meson screen, the closest realistic analog to the classic "force field" of science fiction. The protected target (usually a vehicle or aircraft) is surrounded by a low-power static field linked to a fully charged high-energy capacitor. When an object enters the field (and provided it falls within fairly narrowly defined parameters for mass and velocity) the capacitor discharges its energy which vaporizes the foreign object.

The massive power discharge is triggered by entry of detectable mass in the field, and so it has no effect on lasers and no significant effect on particle accelerator weapon systems (PAWS). It was originally designed as a counter to hyper-velocity tank rounds, but it is difficult to generate sufficient power to completely vaporize the dense penetrators of most large-caliber CPR guns and mass drivers. As a result, electrostatic armor is usually used as an adjunct to, rather than a replacement for, a conventional armored envelope. Due to the low mass of the penetrator stream of a HEAP round or a plasma bolt, however, electrostatic armor is extremely effective against HEAP rounds and both plasma and fusion guns.

ESA systems will have an armor value which is usually added to the base armor value of the protected target. The full AV is added versus HE, HEAP, plasma bolt, and fusion bolt attacks. Half the AV is added versus KEAP attacks. No AV is added versus laser and PAWS attacks.

ESA Design: The ESA system itself consists of a field generator and a homopolar generator. The designer specifies the discharge power, in megajoules, of the field generator. All other values are derived from the field generator's discharge power. The homopolar generator must have a discharge capacity equal to the discharge power of the field generator.

Field Generator

TL	Vol	MCr	AV
9	0.4	1	4
10	0.3	0.8	5
11	0.2	0.6	5.5
12	0.15	0.5	6
14	0.1	0.4	7
16	0.075	0.3	8
18	0.05	0.25	9
20	0.025	0.2	10

TL: Tech level of construction.

Vol: The volume of the field generator, in m³, is equal to its discharge power in megajoules multiplied by the value shown on the table.

MCr: The price of the field generator, in MCr, is equal to its discharge power in megajoules multiplied by the value shown on the table.

AV: The armor value of the system is equal to the discharge power (in megajoules) multiplied by the value shown on the table, multiplied by the target size AV multiplier (see table below). This value is used versus HEAP rounds and both plasma and fusion guns. Half this value is used against KEAP rounds.

Target Size AV Multiplier

Size	*Multiplier*
Small or less	1
Medium	.5
Large	.25
Very Large	.12
Gigantic	.06

Mass: Generator mass, in tonnes, is equal to volume in $m^3 \times 2$

Homopolar Generator: Direct electrical power requires the installation of a homopolar generator (HPG), see the Power Production chapter (Section 8). The HPG must be of sufficient size to store the ESA's one-shot energy output as defined immediately above. Calculate the volume of HPG needed by multiplying the ESA's discharge energy (DE) in MJ by the value on the HPG table.

Rate of Fire: Define the ESA's rate of fire (ROF). As ESAs have no effect on lasers and PAWS, they are used almost exclusively in planetary combat and so ROF is calculated on the basis of a five-second combat turn. The rate of fire is equal to the continuous power input from the power plant, in megawatts, multiplied by 5 and divided by the discharge power in megajoules. The result is the number of times per five-second combat turn that the ESA will add its value to the vehicle's basic armor.

Note that in many cases the ROF value will be less than 1. In this case, the ESA homopolar generator requires one or more turns to recharge before it can be used again. Divide 1 by the ROF result, rounding all fractional results up, to determine how many turns the homopolar generator must recharge before it can fire again.

Explosive Power Generation: Some ESA systems are not tied to a continuously running power plant, and instead rely upon explosive generation of power to recharge the homopolar generator. See the Power Production chapter (Section 8) for details of explosive power generators.

TRACTORS AND REPULSORS

Both tractors and repulsors are advanced devices based on artificial gravity technology. Tractors are large, focused artificial gravity attractors. When directed at other craft, they draw them in or restrict their agility. Repulsors are large, focused but negatively polarized artificial gravity projectors available at very high tech levels. When directed at incoming missiles or other foreign objects, they deflect them away from their target.

The performance of both tractors and repulsors is expressed in terms of tonnes of thrust per cubic meter of projector. If a tractor or repulsor operator makes a successful task roll, the power of the weapon may be applied to the target, either as acceleration toward (tractor) or away from (repulsor) the projector.

The manipulator is a combination tractor/repulsor which allows fine control over the object being targeted. Because a tractor can only pull objects toward itself, it cannot stop them once they are close aboard. A manipulator can apply tractor and repulsor thrust to an object to place it beside the projector at a relative net vector of zero. Manipulators are often installed in large, otherwise empty bays which they load with large, unwieldy cargoes, and then unload at the destination.

The table in the next column shows the tonnes of thrust generated per kiloliter (cubic meter) of tractor or repulsor projector installed.

			Tonnes per kiloliter of projector at tech level				
Type	*Price*	*Power*	*12*	*14*	*16*	*18*	*20*
Tractor	.1	.01	3	30	300	600	1500
Repulsor	.2	.02	—	—	200	400	800
Manipulator	.3	.02	—	—	200	400	800
Range Modifier			.1	.01	.001	.0001	.00001

Price: Millions of credits per cubic meter of projector.

Power: Power requirements are in megawatts per tonne of applied thrust.

Mass: Mass in tonnes of any gravitic projector is equal to its volume in cubic meters.

The system requires a workstation and a beam pointer to function. The beam pointer determines the range of the weapon for purposes of achieving a hit. However, power drops dramatically with range. Divide power by the the product of the range in kilometers multiplied by the tech level range modifier, shown on the bottom line of the table. However, any product of range times modifier less than 1 is rounded up to 1.

FORCE FIELDS

True force fields are a result of an increased ability to manipulate subatomic particles as well as a deeper understanding of the sensitivity of those to electromagnetic radiation. The earliest force fields are called black globes, due to the fact that they are effectively opaque to all forms of matter and electromagnetic energy encountering the field from both the inside and outside. Since they absorb all light, from both the inside and outside they look completely black.

The field itself is a cloud of free electrons held in place by an electromagnetic field. Free electrons are those which are not bonded to an atomic nucleus, and are therefore capable of absorbing and emitting electromagnetic energy of any wavelength. Early descriptions of black globes as "free electron lasers in reverse" are not entirely accurate, but it is true that the same characteristics of free electrons which make FELs possible are utilized in the force field.

Since early versions of the field were omnidirectional, ships with the field up were unable to sense targets, fire, or maneuver. At short range, this presented tremendous tactical problems, since the lack of maneuverability made the target solution by hostiles trivial and allowed an enemy to simply pump energy into the globe (by means of any and all directed energy weapons) until the field collapsed. The solution was to "flicker" the black globe, allowing the ship to maneuver, sense, and fire while absorbing a portion of the incoming energy of weapons. While maneuver was limited, firing by energy weapons was at full effectiveness: The pulses of the ship's energy weapons were timed to the flicker of the shield much as with the interruptor gears on primitive propeller-driven fighter aircraft. Higher tech levels allowed a more rapid flicker rate.

The next step beyond the black globe, however, was the white globe, a unidirectional force field that allowed a ship to maneuver and fire while completely shielded from enemy fire. Because the field is unidirectional, energy can pass freely out through the barrier, but this still poses difficulties for incoming communications and sensor data. As a result, white globes are tuned to allow certain narrow wavelengths of energy through. These are usually wavelengths which are not particularly useful for weaponry, particularly space-based weaponry. White globe-equipped ships thus tend to rely heavily on infrared wavelength radiation for sensors and make extensive use of masers for tight beam communication.

A critical concern in force field architecture is what to do with the energy the field absorbs. Black globe-equipped ships store it in HPG banks and in combat often shut down their power plants, substituting energy from the HPG banks to power critical ship systems. Some vessels mount additional large lasers or particle weapons which are not normally powered by the ship's power plant, and instead are fed solely by intercepted incoming energy from hostile fire.

White globes have less problem with radiating energy, as the electron globe of the field can radiate energy outward as easily as it can absorb it (which is why it glows white while in use). The energy is first cycled through the system's HPG bank, however, and is then discharged back to an unengaged part of the electron cloud for transmission outward. As a result, white globes are not limited in the total amount of energy they can absorb, but only in the volume of energy they can process in a given amount of time. This is determined by the size of the HPG banks and engineers refer to this limit as the "traffic flow ceiling."

Important Note: If an erected force field comes into contact with large quantities of matter (a vehicle of 50 displacement tons or greater, a large asteroid, planet, etc.), the generator is immediately overloaded and destroyed, and its HPG sink immediately suffers a catastrophic detonation, causing 1D20 critical hits. As the field attempts to drain all of the kinetic energy of the large mass, cooling it to absolute zero, energy is drawn from the entire mass to be drained by the globe, rapidly overloading the generator, as it cannot possibly contain all of the energy in a system that large.

DESIGNING FORCE FIELDS

Force field defensive systems consist of two subcomponents: the force field generator and the homopolar generator/energy sink. Force field generators are described on the following table.

Force Field Generators

TL	Type	Flicker	Power	Vol	MCr
15	Black	10%	15	135	400
15	Black	20%	20	200	600
15	Black	30%	25	270	800
15	Black	40%	30	350	1000
16	Black	50%	35	300	500
16	Black	60%	40	400	700
17	Black	70%	45	450	900
18	Black	80%	45	250	500
19	Black	90%	45	250	500
20	White	—	50	300	900
21	White	—	50	400	910

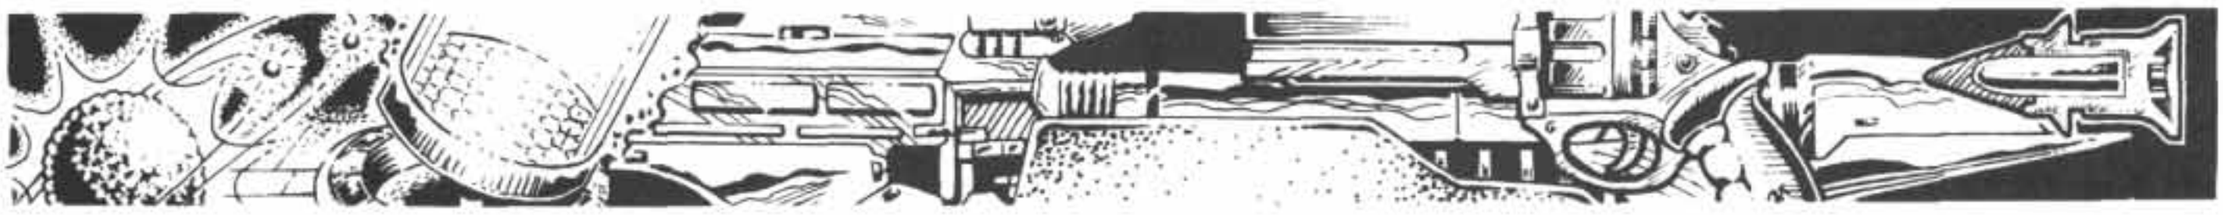
TL: Tech level of first availability.
Type: Black globe or white globe.
Flicker: Operational flicker rate.
Power: Megawatts of power input required for operation of the generator.
Vol: Volume in cubic meters of the generator.
MCr: Price in millions of credits of the generator.
Mass: All generators mass 1 tonne per cubic meter.

Protected Volume: Power requirements increase as the volume of the protected target increases. Multiply those values by the ship's target size multipliers shown in the Target Size Multiplier table:

Target Size Multipliers

Size	*Multipliers*
VS and smaller	×1
S	×2
M	×3
L	×4
VL	×5
G	×6

Note that deployed folding HRT or Passive EMS arrays increase the effective target size of a ship for purposes of force field protected volume. On the following chart, use the diameter of the deployed sensor to find the minimum protected volume required, which reads out in target size as used on the Target Size Multipliers table above. This will require a greater amount of power to run the force field. If insufficient power is provided to run the field at the larger volume required for the extended array, the sensor must be retracted, and may not be used while the force field is on.



Sensor Array Minimum Volume

Antenna Diameter	*Min Vol (Target Size)*
10 or less	SM
20	Mc
40	VS
90	S
200	M
400	L
800	VL
1200+	G

HPG Bank: Any size homopolar generator may be selected for the system. The storage capacity of the HPG subcomponent (or HPG bank) is the maximum power which may be stored by a black globe before catastrophic discharge. White globes are continuously discharging, so there is considerably less danger of an overload. However, incoming power is still cycled through the system and the peak power per 30-minute starship combat turn which can be processed by the field is equal to the power of the installed HPG system. The peak power per five-second planetary combat turn which can be processed by the field is equal to the above value divided by 360.

Note that 35% of the volume of a jump drive consists of capacitor/HPG banks. The jump drive capacitors may be used to store energy along with/in lieu of specifically installed HPGs. Multiply the jump drive volume by 0.35, and divide the result by the correct TL entry on the Homopolar Generator Energy Capacity table. This is the capacity of the jump drive HPG/capacitors in megajoules. Add this to the capacity of the specially installed HPGs to get the total traffic flow ceiling.

Solar Array: Black globes function as excellent solar arrays for ships with power plant damage. Look on the Sensor Array Minimum Volume table, and find the number in the "Antenna Diameter" column corresponding to the chosen protected volume. A full-up black globe in the habitable zone of a star produces power in megawatts equal to 0.1 times the Antenna Diameter figure squared (multiply this value by 10 in the inner zone, and by 0.01 in the outer zone). If the globe is set to flicker, multiply this result by the flicker rate.

CHAPTER 7
Optional Features

These items are used almost exclusively on spacecraft, and constitute an assortment of features which do not fall into any other major category.

Fuel Scoops

Fuel scoops may be added to any design. These allow a vessel to skim the free raw materials for liquid hydrogen (LHyd) fuel from oceans or gas giant atmospheres. They do not consume any volume or add to the mass of the vessel. Fuel scoops do consume surface area. Each 5% of a craft's total surface area given to fuel scoops allows the craft to scoop fuel equal to 20% of its total volume per hour (i.e., a 100-ton ship with fuel scoops covering 10% of its surface can scoop 40 displacement tons of fuel per hour). Cost to add fuel scoops to a design is MCr0.000075 per cubic meter of hull.

Fuel Purification Plant

TL	*MW*	*Vol*	*Mass*	*MCr*	*MinVol*
8	0.01	0.7	1.5	0.0002	135
9	0.009	0.6	1.2	0.00019	120
10	0.008	0.55	1.1	0.00018	105
11	0.007	0.45	0.9	0.00017	95
12	0.006	0.4	0.8	0.00016	80
13	0.005	0.35	0.7	0.00015	65
14	0.005	0.25	0.5	0.00014	55
15	0.005	0.2	0.4	0.00015	40
16	0.005	0.15	0.3	0.00016	25
17	0.005	0.1	0.2	0.00017	15
18+	0.005	0.05	0.1	0.00018	5

Vol: Volume in cubic meters.
Mass: Mass in tonnes.
MCr: Price in millions of credits.
MW: Power requirement in megawatts.
All values are per kiloliter of fuel processed per 6 hours.

Special Facilities

Description	*Vol*	*Mass*	*MCr*	*MW*
Electronics Shop	84	40	1	0.6
Machine Shop	140	120	2	1
Laboratory	112	50	5	0.8
Sick Bay	112	50	5	0.8

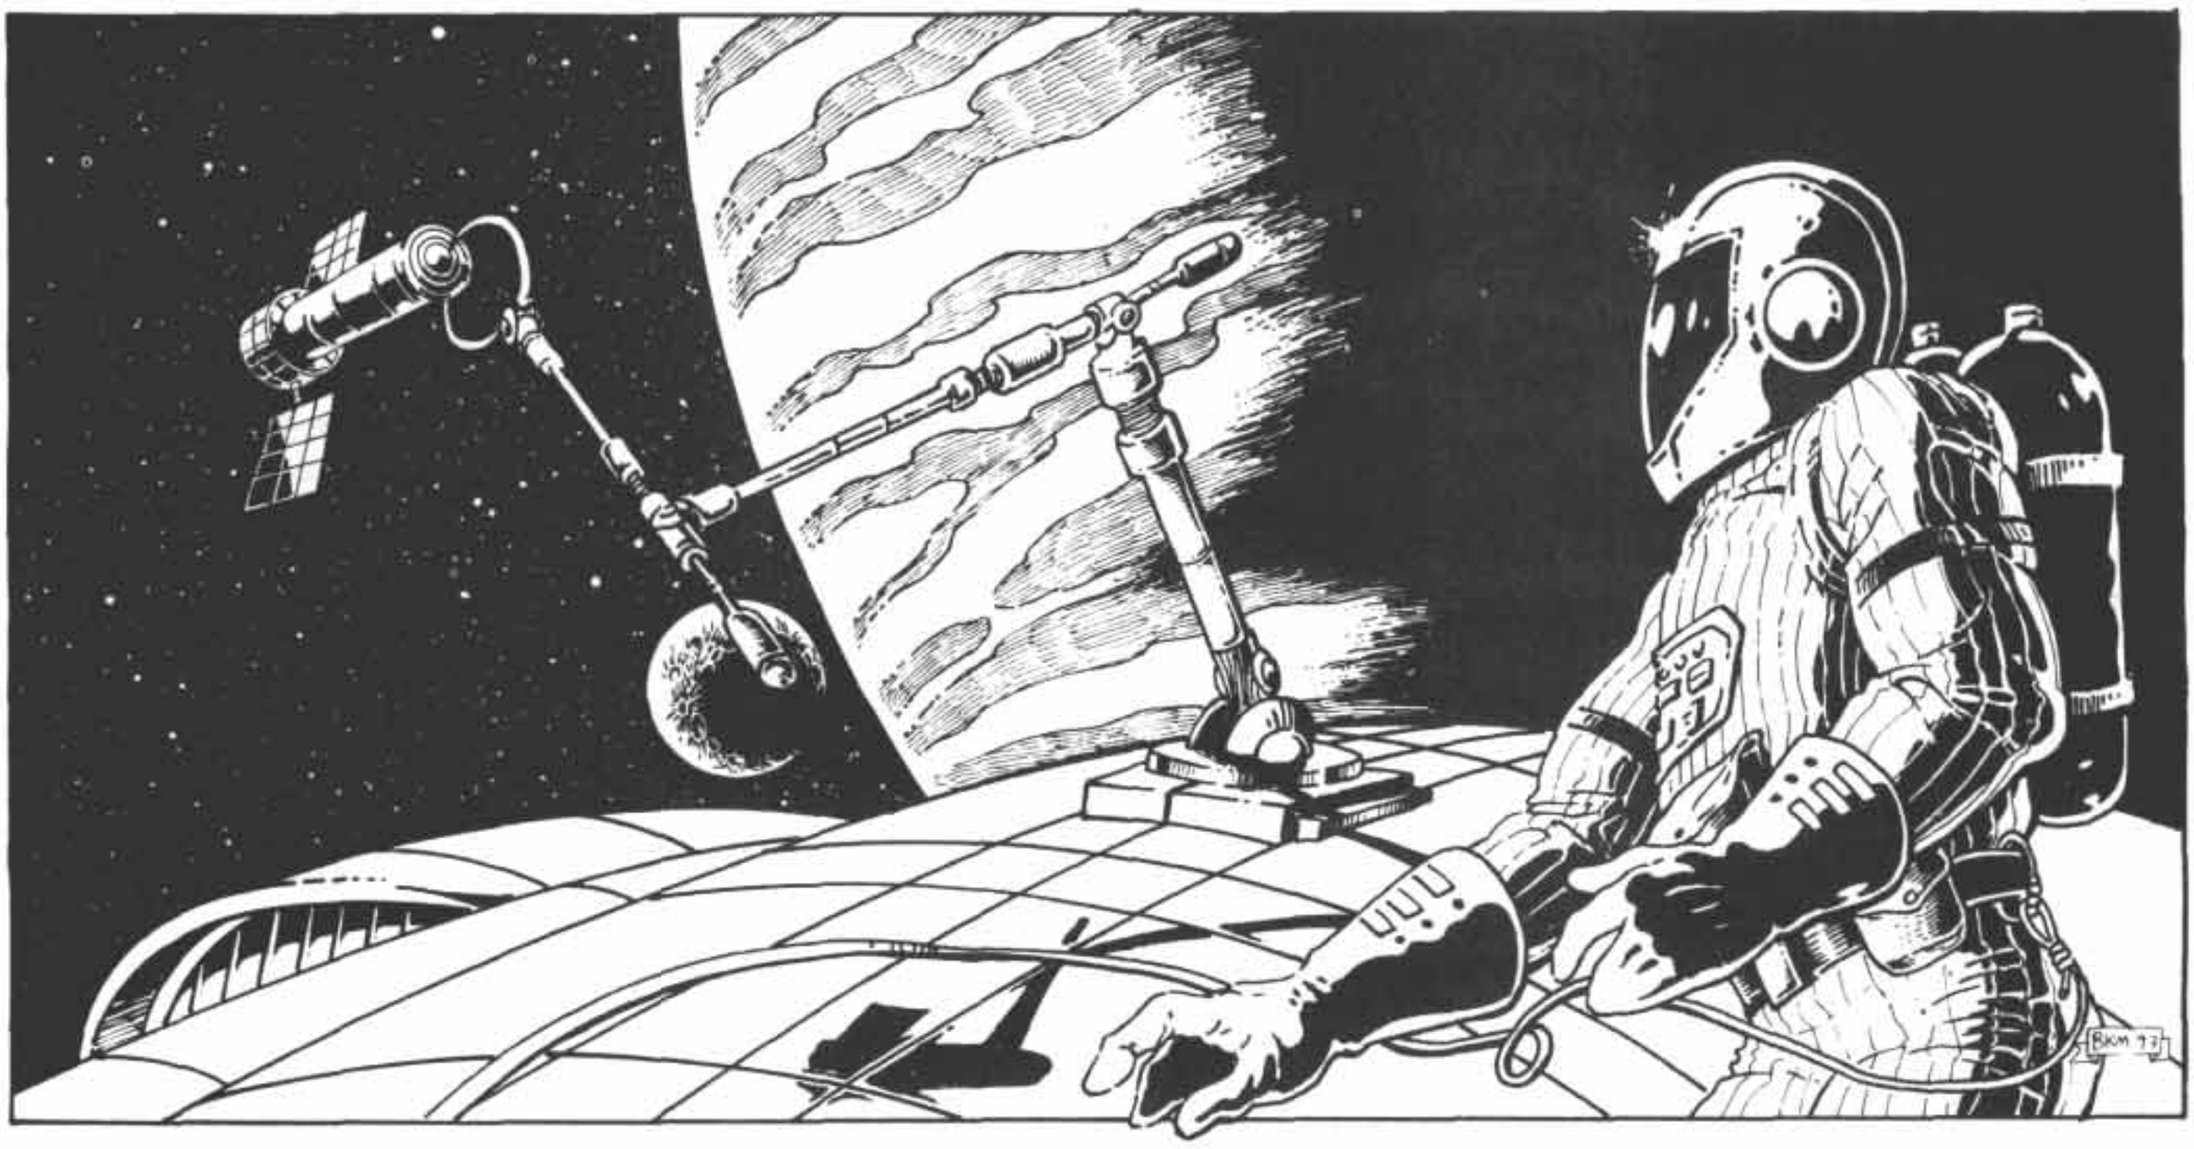
Vol: Volume in cubic meters (kiloliters).
Mass: Total mass in tonnes.
MCr: Price in millions of credits.
MW: Power requirement in megawatts.

Vehicle Service Facilities

Description	*Vol*	*Mass*	*MCr*	*MW*
Internal Hangar (Minimal)	×2	0.2	.0002	—
Internal Hangar (Spacious)	×4	0.2	.0002	—
Docking Ring	×1	0	.0002	—
Launch Tube	×25	0.5	.00015	.01
External Grapple (USL)	×0.1	1.0	.001	—
External Grapple (SL)	×0.3	1.0	.002	—
External Grapple (AF)	×0.5	1.0	.003	—

Volume: Multiply the craft or vehicle volume by the value shown to determine the facility volume.

Mass: The mass in tonnes per cubic meter of installation.



MCr: The price, in MCr, per cubic meter of installation.

Surface Area: All of the facilities require surface area except for the hangars (which require launch ports, below). The launch tube requires area in m^2 equal to $2 \times L^2$ where L equals the basic length as taken from the Hull Size table, unmodified by hull form, of the largest craft that will use the tube.

Grapples require area equal to the square of the final length of the craft carried by the grapple.

MW: Power requirement per cubic meter of installation.

Hangar Space: Spacious hangars allow all repair and maintenance

tasks to be conducted at normal difficulty levels. Minimal hangars increase the difficulty level of all such tasks by one level. Docking rings allow no maintenance or repair.

External Grapple: Types listed are for unstreamlined (USL), streamlined (SL), and airframe (AF) hulls of the carrying ship, not the carried craft. Note that the volume of craft carried in external grapples is not subtracted from the available hull volume of the carrying ship, although the volume of the grapple is. Remember that the volume of the carrying ship plus all externally carried craft is used when calculating the required amount of maneuver drive and jump drive.

By selecting the type of grapple that corresponds to its hull streamlining, the vessel may carry externally mounted craft without compromising its streamlining configuration, so long as the externally mounted craft also meets that configuration. If the grapple or craft's configuration is lower than that of the overall hull, the ship is limited to the lower configuration if it is carrying the craft. If the craft is detached, the hull's configuration may be used.

ACCESS PORTS

Description	*Area*	*MCr*
Launch Port	L^2	0.001
Large Cargo Hatch	20 m^2	0.02
Small Cargo Hatch	12 m^2	0.012

Area: Hull surface area required.

L^2: The square of the craft's basic length as taken from the Hull Size table, unmodified by hull form.

MCr: Price in MCr per square meter of launch port, or per each cargo hatch.

Launch Port: At least one launch port is required if craft or vehicles are carried. More launch ports allow craft to be launched more rapidly.

Cargo Hatches: All craft require at least one large cargo hatch per 350 m^3 (25 tons) of cargo capacity. Vessels with under 100 m^3 of cargo space can get by with a single small cargo hatch.

Seats

Short-haul vehicles will require passenger seats.

SEATS

Access	*Vol*	*Mass*	*MCr*
Restricted	1.5	0.02	.0001
Cramped	2.5	0.02	.0001
Adequate	3.5	0.02	.0001
Roomy	7	0.02	.0001

Vol: Volume in m^3 per position/seat.

Mass: Mass in tonnes per position/seat.

MCr: Price in megacredits per position/seat.

These entries are simple seats with no controls. Paying passenger seats must be Adequate or better; seats for troops must be Cramped or better. "Restricted" access is the minimum possible accommodation for special purposes only.

Drop Tanks

Ships may be fitted with drop tanks if desired. A drop tank is an additional hull section filled entirely with fuel. Its material volume and mass are calculated just as if it were a separate ship, and it must use the same hull form and configuration modifiers as the ship it will be fitted to, and must be armored and have internal structure bracing sufficient to withstand the ship's rated acceleration.

If a drop tank is fitted to a ship with electromagnetic masking (EMM), the tank(s) must also be so fitted, with the volume and surface area taken out of the tank itself. Power requirements are assumed to be met by the carrying ship, which must allow for them in its own design. If any EMM-fitted ship is carrying non-EMM drop tanks, the ship loses all of its EMM benefits until the tanks are dropped.

A drop tank is designed to be released once it is drained, allowing improved performance by the ship.

Collapsible Tanks

Insulated fuel bladders may be carried in the cargo hold to carry additional fuel. This fuel may not be used directly, but must be pumped into the normal fuel tanks for use. Collapsible tanks cost Cr100 per cubic meter of fuel capacity, and when empty can be stored at 5% of their full volume.

Dismountable Tanks

Dismountable fuel fuel tanks may be carried in the cargo hold to carry additional fuel. Fuel from these rigid tanks may be used directly, without requiring transfer to the permanent tanks. Dismountable tanks cost Cr200 per cubic meter of fuel capacity, but must be stored at their full volume when empty. Modified versions costing Cr500 per cubic meter function the same, but may be disassembled to store at 25% their full volume.

Internal Armor

Valuable internal systems may have additional armor added around them. Any time a hit is rolled against such a system, the remaining damage value must first penetrate this internal armor before it can damage the system.

Calculate the volume of the system(s) to be protected, and then design the armor as if it were a separate hull, using the same procedure used to calculate the hull shell (or chassis armor material volume, if it is a vehicle) volume, weight, and price of the ship. Select the armor thickness desired, and use the hull form modifier as used by the main hull. Do not, however, use the minimum armor level based on G performance, and do not apply the airframe configuration modifier. There is no internal structure requirement for internal armor.

Spacecraft Deckplans

Each displacement ton is drawn as a grid square 2 meters by 2 meters, with a vertical height of 3.5 meters. Much of this vertical height is taken up by deck thickness, lighting, environmental ducting, etc., so that free height is only about 3 meters.

When allocating space within the craft, assume that only a portion of the specified volume for staterooms, bunks, etc., is used for those fittings *per se*; the remainder should be used for common areas and other accommodations for the crew, such as recreation areas, eating spaces, and so on.

When comparing the final number of grid squares used on the deckplan to the rated tonnage of the vessel's design, allow a 10-20% leeway. If the plan comes within 20% of the stipulated volume, it is acceptable.

When drawing passenger seats, Roomy seats fit two per grid square; Adequate seats fit four per square; Cramped seats six per square; and Restricted seats nine per square.

CHAPTER 8
Power Production

The extraction of energy from fuel and conversion of that energy to a useful form is the heart of the industrial revolution of tech level 3.

FUELS

All early fuels are organic in origin. The earliest fuel, of course, was wood, and even early steam engines used wood as a fuel. As the industrial revolution required more energy, and a more portable energy supply, coal became a more common fuel due to its greater energy density. Coal is, of course, also organic in origin, the fossilized remains of long-dead life forms (hence the term "fossil fuels"). Coal is also a hydrocarbon fuel. As demand for portable fuel sources increased, high-energy density distillates of hydrocarbon fuels (either oil or gassified coal) replaced coal as the standard hydrocarbon fuel.

As all hydrocarbons are fossil fuels, worlds without a biosphere are unlikely to have them in significant quantities. Even worlds with biospheres may not have had the right biological and geological history to produce significant quantities of fossil fuels. On these worlds, alcohol distillates are used at early tech levels, but these rely on organic material as well, and so are also unavailable on worlds without biospheres.

The most plentiful fuel in the galaxy is probably hydrogen, and it is free for the taking in the atmospheres of most gas giants. It exists in plentiful quantities in oceans and icecaps as well, but in a less useful form. While hydrogen can be burned in most high-tech hydrocarbon power plants, the energy released by simple hydrogen combustion is exactly the same as the energy required to separate it from the oxygen in water. As a result, worlds with other plentiful but less portable energy sources (such as geothermal, tidal, wind, or solar) may use these "free" energy sources to crack hydrogen from water and thus have a useful portable fuel. Energy-poor worlds, however, will not gain anything by using scarce energy to crack hydrogen, since they gain no energy in the process.

They gain nothing in the process assuming, of course, that they are burning hydrogen in a chemical power plant. If they are using it in fusion reactors, the story is considerably different. Once fusion power is available, worlds with considerable water have solved the worst of their energy problems.

The interim step between chemical power plants and fusion is fission. Fission relies upon naturally occurring radioactive elements for fuel, and these are scarce enough throughout our region of space to make them high-priced and highly sought-after.

FUEL

Type	*Mass*	*Price*
Wood	2.0	.000050
Alcohol	1.0	.000200
Coal	2.0	.000100
Hydrocarbon Distillates (HCD)	1.0	.000250
HG Hydro Distillates	1.0	.001000
Liquid Rocket Fuel (LRF)	1.0	.001000
Solid Rocket Fuel (SRF)	1.0	.002000
Hydrogen Rocket Fuel (HRF)	0.3	.001000
Liquid Hydrogen	0.07	.000035
Radioactives	19	.075000
Antimatter	0.07	.200000

Mass: In tonnes per kiloliter (m^3).
Price: In millions of credits per kiloliter (m^3).
HG Hydro Dist.: High grade (highly refined to reduce impurities) hydrocarbon distillates. These are used almost exclusively in fuel cells.

Wood, alcohol, and coal are substitutes for hydrocarbon distillates in various engines. Each of these fuels has a different output multiplier and fuel use multiplier as compared to burning pure hydrocarbon distillates.

Fuel	*Output Mult.*	*Fuel Use Mult.*
Wood	0.5	3
Alcohol	0.75	1
Coal	1	1.5

Chemical Power Plants

The term *reciprocating* refers to the back-and-forth motion of the piston. Not only do reciprocating engines need a flywheel to smooth out the uneven application of power, they are inherently inefficient and limited in the power and speed they can develop. As the engine works faster and faster, the forces on the pistons will eventually shake apart the vehicle or destroy the engine.

Steam engines are usually called external combustion, as the fire is outside of the confines of the boiler and engine itself. The internal combustion engine differs in that the fuel is burned inside the engine and the expanding gas of the fuel explosion is itself used, in place of high-pressure steam, to drive reciprocating pistons which turn a drive shaft. As with any engine, the spinning drive shaft can be connected directly to a mechanical contrivance, such as a winch or axle, or it can turn an electrical generator and produce power to run other systems.

Turbines are engines which use spinning fan blades in place of the less mechanically efficient reciprocating pistons.

The most advanced form of chemical power plant is the magnetohydrodynamic (MHD) turbine, which works on a fundamental principle of electromagnetism called Fleming's Left Hand Rule. This principle states that the confluence of a magnetic field and an electrical current passing through a fluid will cause the fluid to be propelled in one direction. When combined with a high-energy turbine, an MHD field produces an extremely efficient power source.

Although the thrust effect is very weak at low levels of magnetism, the efficiency of the turbine increases with the square of the increase in the power of the magnetic field. As a result, efficient MHD power plants become practical only when large superconducting magnets are economically feasible.

CHEMICAL POWER PLANTS

TL	*Description*	*MW*	*Mass*	*MCr*	*Min Vol*	*Kl/Hour*	*Fuel Type*
3	Early Steam	0.10	2	0.0005	0.25	0.2	Hydro. Dist.*
4	Steam	0.20	2	0.0005	0.15	0.15	Hydro. Dist*
4	Int. Comb.	0.30	1	0.001	0.05	0.2	Hydro. Dist
5	Steam Turbine	0.35	2	0.002	1	0.15	Hydro. Dist
5	Imp. Int. Comb.	0.40	1	0.002	0.01	0.25	Hydro. Dist
7	Gas Turbine	0.50	1	0.005	0.5	0.3	Hydro. Dist
8	MHD Turbine	0.60	1	0.01	1	0.2	Hydro. Dist

MW: Output in megawatts per cubic meter of power plant.
Mass: Tonnes per cubic meter of power plant.
MCr: Price in MCr per cubic meter of power plant.
Min Vol.: Smallest possible power plant in cubic meters.
Kl/Hour: Kiloliters (cubic meters) of fuel consumed per hour per MW output.
Fuel: The type of fuel burned. All chemical power plants burn hydrocarbon distillates, but some substitutes are possible.

Alcohol distillates may be substituted for hydrocarbon distillates in all power plants listed, but energy output is multiplied by 0.75.

All power plants from tech level 7 and higher may be designed to burn LHyd (liquid hydrogen) instead of hydrocarbon distillates at no energy penalty.

*Asterisked power plants may substitute wood or coal for hydrocarbon distillates. If wood is used, energy output is multiplied by 0.5 and fuel consumption is multiplied by 3. If coal is used, energy remains the same but fuel use is multiplied by 1.5.

Fuel Cells

Fuel cells burn fuel and take energy from the energetic electrons transferred between the various products of the chemical reaction. Fuel cells, like batteries (page 65) are electrochemical cells and work on similar principles, except that fuel cells are open systems which continue to process fuel and convert it to energy.

Fuel cells are more efficient than most chemical power plants, but are not as economical as the electrodes become contaminated by fuel impurities and require frequent replacement. Only with ultra-pure fuels is this problem avoided, and the added cost of these fuels generally makes them uneconomical. Only where size and fuel efficiency are more important than cost (as with a spacecraft) are they generally cost-effective.

Fuel Cells

TL	*Description*	*MW*	*Mass*	*MCr*	*Min Vol*	*Kl/Hour*	*Fuel Type*
7	Fuel Cell	0.5	1	0.02	.01	0.3	HG Hydro. Dist.
12	Fuel Cell	0.75	1	0.02	.01	0.25	HG Hydro. Dist.
14	Fuel Cell	1.5	1	0.02	.01	0.2	HG Hydro. Dist.
16	Fuel Cell	1.75	1	0.02	.01	0.2	HG Hydro. Dist.

MW: MW output per cubic meter of power plant.
Mass: Tonnes per cubic meter of power plant.
MCr: Price in MCr per cubic meter of power plant.
Min Vol.: Smallest possible power plant in cubic meters.
Kl/Hour: Kiloliters (cubic meters) of fuel consumed per hour per MW output.
Fuel: All fuel cells burn hydrocarbon distillates or LHyd.

Nuclear Power

Nuclear power relies on the energy released by the fission or fusion of atoms in a controlled nuclear chain reaction. Nuclear fission is the splitting of an atom of "fissionable" material, usually a refined isotope of uranium or plutonium. When the atom is split, energy is released. Nuclear fusion is the combination of two atoms, usually hydrogen atoms, into a single atom, also releasing energy in the process. (See the sidebar on common fusion reactions.) In both cases, much of the energy released is in the form of heat. Fission and fusion reactors use the heat to boil water to turn a high-pressure turbine to generate electrical power.

Nuclear Power Plants

TL	*Description*	*MW*	*Mass*	*MCr*	*Min Vol*	*Kl/Year*	*Fuel Type*
6	Fission	0.30	10	0.1	30	0.75	Radioactives
7	Fission	0.60	8	0.1	20	0.25	Radioactives
8	Fission	1.00	6	0.1	10	0.1	Radioactives
9	Fusion	2.00	4	0.2	100	0.15	LHyd
10	Fusion	2.00	4	0.2	50	0.15	LHyd
11	Fusion	2.00	4	0.2	20	0.15	LHyd
12	Fusion	2.00	4	0.2	10	0.15	LHyd
13	Fusion	3.00	3	0.2	1	0.1	LHyd
14	Fusion	3.00	3	0.2	0.25	0.1	LHyd
15	Fusion	6.00	2	0.2	0.1	0.1	LHyd
16	Fusion	7.00	1	0.2	0.075	0.1	LHyd

MW: MW output per cubic meter of power plant.
Mass: Tonnes per cubic meter of power plant.
MCr: Price in MCr per cubic meter of power plant.
Min Vol.: Smallest possible power plant in cubic meters.
Kl/Year: Kiloliters (cubic meters) of fuel consumed per year per MW output.

Common Fusion Reactions

The only achievable fusion reaction on Earth is deuterium and tritium fusion. Thus far, it has only been achieved in H-bombs, but it is hoped that these reactions will eventually be harnessed for controlled fusion power production.

The reaction takes place in three steps:

1) Two deuterium ($_1H^2$) nuclei (each with one proton and one neutron) fuse to form one helium-3 ($_2He^3$) nucleus (two protons, one neutron) and a free neutron.

2) Two deuterium ($_1H^2$) nuclei fuse to form one tritium ($_1H^3$) nucleus (one proton, two neutrons), and a free proton.

3) One deuterium ($_1H^2$) nucleus and one tritium ($_1H^3$) nucleus fuse to form one helium-4 ($_2He^4$) nucleus (two protons, two neutrons), and a free neutron.

The total reaction is summarized as:

Five deuterium ($_1H^2$) yield one helium-3 ($_2He^3$) plus one helium-4 ($_2He^4$) plus one proton plus two neutrons plus energy.

However, the most common fusion reaction in our solar system is the one which powers our sun, and is known as the proton-proton chain. It requires temperatures and pressures far in excess of what can be created on Earth. Like the deuterium-tritium chain above, it too proceeds in three steps:

1) Two hydrogen ($_1H^1$) nuclei (one proton each) fuse to form one deuterium ($_1H^2$) nucleus (one proton, one neutron) plus a positron and a neutrino (the positron collides with a nearby electron almost instantaneously, annihilating both particles, releasing energy). Note that one of the protons has decayed into a neutron, positron, and neutrino.

2) One hydrogen ($_1H^1$) nucleus and one deuterium ($_1H^2$) nucleus fuse to form a helium-3 ($_2He^3$) nucleus.

Each of steps 1 and 2 take place twice to create the material for the last step:

3) Two helium-3 ($_2He^3$) nuclei fuse to form one helium-4 ($_2He^4$) plus two hydrogen ($_1H^1$) nuclei, which start the cycle again.

The total equation is:

Six hydrogen ($_1H^1$) yield one helium-4 ($_2He^4$) plus two hydrogen ($_1H^1$) nuclei, two neutrinos, and energy, or, simplified:

Four hydrogen ($_1H^1$) yield one helium-4 ($_2He^4$) plus two neutrinos and energy.

Matter-Antimatter Annihilation

Antimatter is a collective term for the *antipartides* that correspond to all subatomic particles. A particle and its antiparticle have the same mass but are opposite in electric charge or some other elementary characteristic. The anti-electron, for example, is called the *positron*, and has a positive charge rather than a negative. The difference between matter and antimatter is that, although they both respond in the same way to gravitation, electromagnetic forces, etc., if a particle and its antiparticle collide, they will be completely converted to energy. In fact, this is responsible for part of the energy of a fusion reaction. When hydrogen atoms fuse, one of the byproducts are single positrons which almost immediately collide with an electron, annihilating both and generating energy. One positron is generated for every three atoms of hydrogen which fuse, and the annihilation of this positron accounts for 7.7% of the total energy of the fusion reaction, and a higher percentage of its useful energy.

This quality of complete annihilation of matter and conversion to energy makes matter-antimatter the most energy-dense fuel system possible in the physical universe. It is the only fuel which gives over its entire mass to Einstein's classic equation: $E = mc^2$.

Antimatter is naturally occurring, but not in useful quantities. However, it can be created in high-energy particle accelerators. Antimatter is, therefore, not a natural fuel, but rather a manufactured one. (The distinction is less important than it may at first sound, however, as virtually all high-grade fuels require considerable processing before being used.)

MAA (Matter-Antimatter Annihilation) Power Plants

TL	*Description*	*MW*	*Mass*	*Price*	*MinVol*	*Kl/Year*	*Fuel Type*
17	Antimatter	50	6	0.5	8.000	0.005	Antimatter
18	Antimatter	100	5	0.5	1.000	0.002	Antimatter
19	Antimatter	250	4	0.5	0.250	0.001	Antimatter
20	Antimatter	500	3	0.5	0.100	0.0005	Antimatter
21	Antimatter	1000	2	0.5	0.020	0.0002	Antimatter

MW: MW output per cubic meter.
Mass: Tonnes per cubic meter
Price: Price in millions of credits per cubic meter
Min Vol: Smallest possible power plant in cubic meters.
Kl/Year: Kiloliters (cubic meters) of fuel consumed per year per MW output.

Solar Arrays

Solar arrays consist of solar collectors, which collect solar radiant energy, and solar cells, which convert radiant energy to electrical energy. Each cubic meter of solar cells requires 10 square meters of solar array if deployed in the inner zone of a star system, 100 square meters of solar collectors if deployed in the habitable zone of a star system, and 10,000 square meters of solar collectors if deployed in the outer zone of a star system.

Solar Collector Panels

TL	*Vol*	*Mass*	*MCr*
6	0.3	0.008	0.005
7	0.2	0.006	0.004
8	0.15	0.004	0.003
9	0.1	0.003	0.002
10	0.06	0.002	0.001
11+	0.04	0.001	0.001

Vol: Cubic meters of volume required per square meter of installed collector panels, if permanently installed.
Mass: The mass of the collector, in tonnes, per square meter of panel.
MCr: The price of the collector, in millions of credits, per square meter of panel.

Retractable Array: The values on this table are for rigid, permanently installed solar collectors. If the solar collector is designed to be retracted and deployed at various times, double the price, mass, and volume.

Solar Cells

TL	*MW*	*MCr*
6	0.01	0.5
7	0.015	0.4
8	0.02	0.3
9	0.025	0.25
10	0.03	0.2
11	0.035	0.15
12+	0.04	0.1

MW: Output, in megawatts, per cubic meter of solar cell.
MCr: Price, in millions of credits, per cubic meter of solar cell.
Mass: All solar cells mass 2 tonnes per cubic meter.
Minimum Volume: The smallest allowed solar cell is 0.01 cubic meters.

Batteries

Batteries are not a means of generating power, but rather of storing it. However, the same might be said for artificially generated fuels, such as antimatter. Batteries are often used as surrogate power plants and fuel supplies when the device does not warrant a full-fledged power plant.

BATTERIES

TL	Description	MW	Mass	MCr
4	Storage Batteries	0.04	2	0.001
5	Storage Batteries	0.06	2	0.001
6	Storage Batteries	0.08	2	0.0008
7	Storage Batteries	0.1	2	0.0008
8	Storage Batteries	0.2	2	0.001
9	Storage Batteries	0.4	2	0.002
10	Storage Batteries	0.8	2	0.003
11	Storage Batteries	1	2	0.004
12	Storage Batteries	1.5	2	0.005
13	Storage Batteries	2	2.5	0.008
14	Storage Batteries	2.5	2.5	0.01
15	Storage Batteries	3	2.5	0.015
16	Storage Batteries	3.5	2.5	0.02

MW: Maximum output, in megawatts, at the one-hour discharge rate, per cubic meter of battery.

Mass: Mass of the battery, in tonnes, per cubic meter

MCr: Price, in millions of credits, per cubic meter

Battery Discharge Rate: The battery's discharge time is the time it takes to drain the battery's charge. The energy output on the table above assumes a discharge time of 1 hour. If the output is lowered, the discharge time is increased, as shown below. Note that some discharge times are only available at higher tech levels.

Output	Time	Price	TL
×15,625	0.0036 seconds	×25	9
×3125	0.036 seconds	×16	8
×625	0.36 seconds	×9	7
×125	3.6 seconds	×4	6
×25	36 seconds	×2	5
×5	0.1 hour	×1	4
×1	1 hour	×1	4
×0.1	10 hours	×1	4
×0.02	100 hours	×1	5
×0.004	1000 hours	×1	6

Capacitors and Homopolar Generators

Like batteries, capacitors and homopolar generators (HPGs) are not means of generating power, but rather of storing it. They are included here because they are usually used in conjunction with some means of generating energy.

Capacitors and HPGs are treated together because both perform the same function. They hold very large amounts of energy (usually for fairly short periods of time) and then discharge the energy very quickly. Capacitors are used at the earliest tech levels, but are quickly replaced (over the course of tech level 8) by HPGs for larger jobs. The table below represents the best performance at tech level and assumes designers will use the most appropriate technology.

Capacitors store electricity directly as an electromagnetic charge; HPGs convert electricity to kinetic energy, storing it in a rapidly spinning flywheel. When a charge is passed through the generator, the flywheel slows rapidly, converting energy to electricity in a powerful discharge.

The following table shows volume of capacitors and HPGs per Mj of stored energy.

HOMOPOLAR GENERATOR ENERGY CAPACITY

TL	Cubic Meters of HPG per Mj
7	0.25
8	0.125
9	0.1
10	0.08
11	0.06
12	0.05
13	0.045
14	0.04
15	0.035
16	0.03
17	0.025
18	0.02
19	0.015
20	0.01
21	0.005

Vol: Volume, in cubic meters, is equal to megajoules of stored energy multiplied by the value shown on the table.

Mass: Mass in tonnes is equal to volume in cubic meters × 2.

Price: Price, in millions of credits, is equal to volume in cubic meters multiplied by 0.01.

Explosive Power Generators (EPG)

EPG is a means of generating a large amount of power quickly, and it is useful for systems requiring quick surges of power. It was first used to generate large power surges by the Soviet Union in the 1980s as part of their beam weapon research program. By tech level 9, field versions become reasonably practical, and by tech level 12 pulse plasma cartridges (PPC) make it an extremely efficient means of generating quick surges of power.

Each EPG system consists of a homopolar generator and power cartridges. EPG output is generally expressed as pulse energy and measured in megajoules. The homopolar generator is modified slightly to enable it to convert the energy of the power cartridge to electrical energy. This modification increases the cost of the homopolar generator by 10% but has no effect on volume or mass.

Each EPG system requires five seconds (one combat round) to eject a spent cartridge and load a new one, giving the generator a normal cycle time of one pulse per combat turn. This may be increased by building a multiple feed generator (one which holds more than one cartridge at the same time). Each additional cartridge held increases the mass, volume, and price of the generator by 5% and adds 1 to the number of pulses allowed per combat phase.

Explosive power cartridges are designed using the table below. Cartridges are usually cylindrical in shape and are three times as long as their diameter. They usually have a thin metallic covering and a ceramic liner.

TL	*Description*	*Vol*	*MCr*
9	Chemical Explosive Cartridge (CXC)	.001	.001
10	Chemical Plasma Cartridge (CPC)	.0006	.0001
12	Pulse Plasma Cartridge (PPC)	.0003	.000025
14	Pulse Fusion Cartridge (PFC)	.0002	.000008
16+	Gravitic Compression Fusion Cartridge (GCFC)	.0001	.000004

TL: Tech level of availability

Vol: The volume of the cartridge, in cubic meters, is equal to its output in megajoules multiplied by the value shown on the table.

MCr: The price of the cartridge, in millions of credits, is equal to its output in megajoules multiplied by the value shown on the table.

Mass: The mass of the cartridge, in tonnes, is equal to its volume in cubic meters multiplied by 8.

Dimensions: The dimension of the cartridge can be calculated using the following formula:

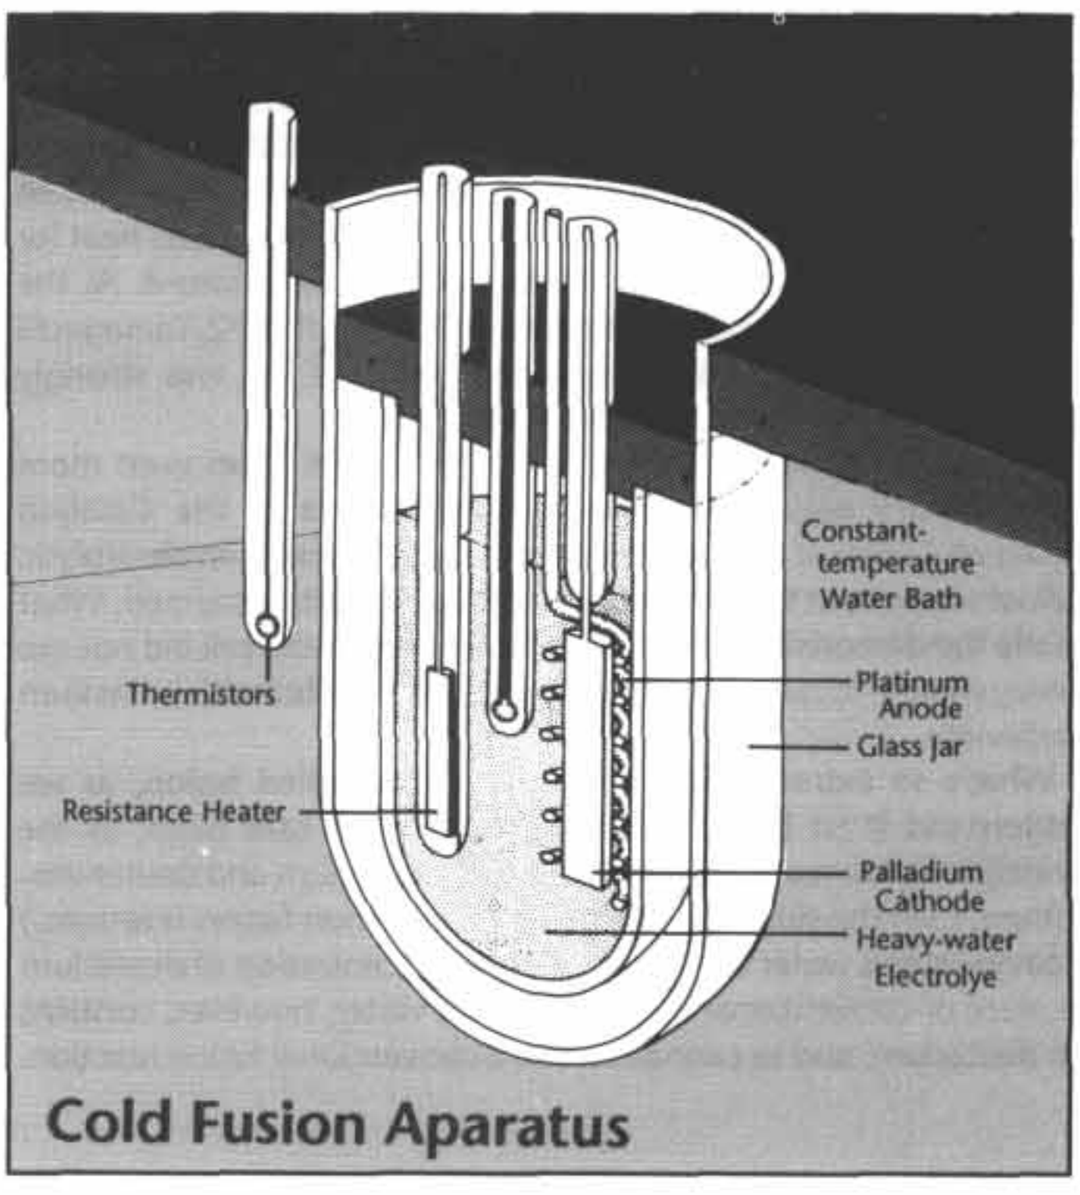
Radius (r) = $0.376 \times \sqrt[3]{Vol}$ (Volume in m^3, r in meters)
Diameter = 2r
Length = 6r

ALTERNATE TECHNOLOGY

The above range of power-generating means is a reasonable surface coverage of the most important means of power generation likely to be open to mankind over the next few centuries. One important alternate technology is not included in the Imperial Space technological background, and that is piezo-nuclear fusion, which we present here as an alternative.

Piezo-Nuclear Fusion

This type of fusion may never be available, or it may be available long before any of the above advanced forms of power generation. Piezo-nuclear fusion, more popularly known as "cold fusion," was the subject of some controversial scientific research, and sensational news reporting, in 1989. As far as the public was concerned, it all began with a press conference in March of 1989 in Salt Lake City when Drs. Martin Fleischman and B. Martin Pons announced that they had discovered a cold-process for fusion.



The apparatus used a platinum anode and palladium cathode in a bath of heavy water. Electricity separated the deuterium (a heavy isotope of hydrogen) from oxygen in heavy water and then attracted the deuterium to the palladium cathode. The hydrogen then penetrated the palladium and under high pressure (hence the term *piezo*, or "squeeze") began to fuse, heating the cathode and giving off about four times as much heat energy as was used to run the machine.

Or so they reported. There was an immediate flurry of activity as skeptical researchers across the world made duplicates of the apparatus and hundreds of experiments were soon running, trying to replicate the results reported by Fleischman and Pons. They were, almost without exception, unable to produce any results. Fleischman and Pons were not physicists but were instead electro-chemists and were, it was speculated, unfamiliar with the rigorous experimental protocols necessary for controlling and measuring energy levels this small. The results they reported were well within the error margin of poorly calibrated instruments.

Within months, the verdict of the scientific establishment was in. The cold fusion process was a dead end. The US patent office refused to issue any patents on cold fusion, citing numerous experimental disproofs of the process. Prestigious scientific journals declined to accept further articles on the subject. Research funding disappeared. End of story.

Almost. The statement above—that attempts to replicate the effects experimentally were "almost without exception" unsuccessful—is significant. A few researchers, both in the United States and abroad, achieved results, and these results remained unexplained. A few scientists continued research on the process, with funding from various sources. Some private money was made available. Some researchers controlled discretionary funding and used it to continue cold fusion experiments. At some labs today, even as this is written, experiments continue using funding diverted from other projects.

But the main source of funding has been Japanese. The powerful Ministry of International Trade and Industry (MITI) funded a three-year project beginning in 1992. Fleishmann and Pons are now working in France at a special laboratory provided by IMRA Europe, the European branch of Toyota's scientific research institute. Nippon Telephone and Telegraph (NTT) has also become a major player in the unfolding research.

Cold Fusion Aparatus

Why had only a handful of researchers been able to replicate the results of the original experiment when the majority had not?
1 Although the answer isn't certain, one possible explanation lies with the characteristics of the palladium cathode. Dr. Edmond Storm at Los Alamos, when examining the cathodes of a number of successful experiments, noted that the surfaces were smooth and unblem-
2 ished, while the cathodes used in many unsuccessful experiments were covered with a network of hairline cracks.

Whatever the reason, by the middle of 1991 there had been over 40 successful replications of the original cold fusion experiment, and
3 repeated successes brought more understanding of the procedures needed to replicate the results on a consistent and predictable basis. In the autumn of 1992, Dr. Michael C. H. McKubre of SRI International reported that 11 of the previous 12 cold fusion experiments at
4 the SRI labs had produced excess heat. Critics remained skeptical, and pointed out that there could be no claim of fusion without fusion byproducts.

When deuterium fuses, it often produces tritium (a triple-heavy
5 form of hydrogen appearing only as a byproduct of nuclear reactions) and eventually helium-4 (a byproduct of deuterium-tritium fusion). Without tritium and helium-4 it is difficult to believe that fusion is taking place. Dr. John Bockris of Texas A&M has now
6 reported detecting tritium in the heavy-water bath of a cold fusion device which reached 10,000 times the normal background concentration. Other researchers have begun to find tritium as well, and Bockris has reported from 2 to 100 times more helium-4 in the
7 palladium cathodes of experimental devices than found in samples of palladium from the same production batch but not used in experiments. Helium-4 residue has also been reported by experimenters at the University of Hawaii, the University of Texas, and the Naval Weapons Center at China Lake, California.

8 Intriguing as these results are, they do not demonstrate conclusively that the helium-4 was actually produced by a fusion reaction. If fusion is taking place, it should be possible to observe the
9 production of helium-4 while the reaction takes place. Dr. Eiichi Yamaguchi of NTT's Tokyo basic research lab has apparently done exactly that. He has taken a piece of palladium, coated on one side with gold, saturated it with deuterium gas, enclosed it in a vacuum chamber, and run an electric current through it. After two or three
10 hours, the palladium begins to heat up, generating excess heat for about 15 minutes, and then releases a burst of helium-4. At the Nagoya, Japan, cold fusion conference in October of 1992, Yamaguchi
11 reported: "The amount of produced helium-4 gas was strongly correlated to the excess heat evolution."

But at the same conference, a demonstration of an even more revolutionary nature was made. Reiko Notoya of the Catalysis Research Center at Hokkaido University demonstrated an electrolytic
12 cell which put out three times as much energy as it consumed. What made the demonstration extraordinary was that the cell did not use heavy water—it used regular (or "light") water salted with potassium carbonate.

13 What's so extraordinary about that? Controlled fusion, as we understand it on Earth, requires deuterium to take place, as the principle fusion reactions are deuterium-deuterium and deuterium-tritium. (See the sidebar on page 63 on common fusion reactions.)
14 Heavy water is water containing a high concentration of deuterium in place of conventional hydrogen. Light water, however, contains no deuterium, and so cannot sustain a conventional fusion reaction.

There seems to be little question that something is going on here. Light water reactions were first reported by Dr. Randall Mills, a private researcher living in Lancaster, Pennsylvania. Since then, and in addition to Notoya's repeated demonstrations, Bush and Eagleton of California Polytechnic have built and operated 19 light water cells and the Bhabha Atomic Research Center of India has run 29 different light water cells. But is it fusion?

Obviously it cannot be fusion as we expect to find it on Earth if there is no deuterium present. However, the light water cells use potassium carbonate as a salt in the water. If a hydrogen nucleus (a single proton) were to fuse with a potassium nucleus, the result would be calcium. Both Bush in California and Notoya in Japan have detected calcium in the electrolyte after the cell has operated for an extended length of time. The excess energy produced by the cell is greater than can be explained by mechanical or chemical reactions. It may not be fusion—but what is it?

Are we on the verge of a dramatic breakthrough in power-generating technology or will this latest round of experimental results turn out to be scientifically intriguing but of little practical value? It is impossible to tell, but it makes for an interesting optional power source with more than a little basis in fact.

The advantages of piezo-nuclear fusion are staggering. There are no bottom limits on the size of the device. It is lightweight, since it does not need heavy shielding (it is not "hot" in a radioactive sense). It is not dangerous. It can conceivably run off of water, without too much preliminary fuss. For campaigns that require very portable, very long-lived power sources, piezo-nuclear fusion is the perfect answer.

Piezo-Nuclear Fusion (PNF) Power Plants

TL	*Description*	*MW*	*Mass*	*MCr*	*Min Vol*	*Kl/Hour*	*Fuel Type*
9	PNF	0.40	1	0.005	—	0.002	H_2O
10	PNF	0.50	1	0.005	—	0.002	H_2O
11	PNF	0.60	1	0.005	—	0.002	H_2O
12	PNF	0.80	1	0.005	—	0.002	H_2O
13	PNF	1.00	1	0.005	—	0.002	H_2O
14	PNF	1.25	1	0.005	—	0.002	H_2O
15	PNF	1.50	1	0.005	—	0.002	H_2O
16	PNF	2.00	1	0.005	—	0.002	H_2O

MW: Power in megawatts produced per cubic meter of plant.
Mass: In tonnes per cubic meter of plant.
MCr: Price in millions of credits per cubic meter of plant.
Min Vol: Minimum volume, in cubic meters.
Kl/Hour: Kiloliters (cubic meters) of fuel consumed per hour per MW output.
Fuel Type: Water.

CHAPTER 9
Sublight (Maneuver) Drives

Traveller is scientifically based for much of its technology, but is not strictly speaking a "hard science" game. Instead, it is a reasonable compromise between hard science and science-fiction adventure literature, and this shows up in the mathematics of maneuver drives among other places. This compromise is represented in two aspects of maneuver drive design: thrust requirements and fuel consumption.

Thrust requirements are abstracted by tying thrust energy requirements to hull displacement rather than craft mass. This is an obvious abstraction, but one which is necessary for ease of design. Too many variables affect ship mass throughout the design process, and tying thrust to mass would require you to continually re-design and re-design to get a workable craft. In our opinion, the thrust-to-mass formula is a workable compromise, especially since spacecraft tend to have the same general density. The correction factor for very high mass-to-volume designs takes care of any important distortions.

The fuel requirements for the TL-10 maneuver drive reaction mass are considerably lower than for current or projected technology thrusters. The standard maneuver drive in **Traveller**, which appears at tech level 10, is called the High-Efficiency Plasma Recombustion (HEPlaR) drive, which uses hydrogen as propellant/reaction mass, super-heating it to a plasma state in an ignition chamber and expelling it out the back of the vessel. Note that this is not a fusion rocket, and while the exhaust is a super-heated plasma, it is not radioactive. While the principle of the drive is scientifically sound, its game representation is extraordinarily fuel-efficient.

By way of comparison, take a look at NASA's space shuttle. It is almost all fuel tank, and that is just to boost a modest payload into low Earth orbit (LEO). It is not capable of escaping Earth orbit or conducting interplanetary travel. A first possible alternate universe would be to ignore the HEPlaR maneuver drive and stick with lower-tech drives. Ships built based on that earlier level of thruster fuel efficiency would be much different than **Traveller** ships, and the economics and logistics of interplanetary travel and exploration would be completely different. It would not be the **Traveller** universe, but it would still be an interesting universe.

Maneuver Drive Design

Thrust requires both energy and reaction mass, and so additional fuel tankage will be required as well. Thrust is measured in tonnes. Spacecraft require (for the sake of simplicity) 10 tonnes of thrust per displacement ton to achieve an acceleration of 1G. Spacecraft with a final mass of more than 15 times (rounding fractions to the nearest whole number) their hull rate (in displacement tons) should recalculate their acceleration based on the actual thrust-to-mass ratio, dividing thrust (in tonnes) by mass (in tonnes) to determine acceleration in Gs. Most spacecraft, however, will mass less than 15 tonnes per displacement ton.

Aircraft, which are designed around their weight rather than their volume, require 1 tonne of thrust per tonne of craft weight to achieve 1G of acceleration. Most aircraft, particularly at early tech levels, will have less than 1G of acceleration.

Thrust is produced in one of two ways: either by means of a thrust agent added to an existing power plant or by means of a dedicated self-contained thruster.

A thrust agent is a mechanical means of converting the power produced by a power plant (either electrical power from a dynamo, heat from combustion, or the physical power of a turning drive shaft) into thrust.

Propellers: A propeller is the most common thrust agent at lower tech levels.

Note that aircraft engines used to drive propellers have only half the volume per output power as conventional engines, for three reasons. First, virtually no volume is used for maintenance access. The next time you open the hood of your car, look at how much of the volume of the engine compartment is consumed by open space. This open space serves a purpose—maintenance access. If the engine is too compactly installed, mechanics cannot get to various parts of the engine to check them or replace components. An aircraft engine, however, is mounted at the end of the fuselage or in a wing nacelle, and in either case no internal volume is used to provide access. Instead the entire engine is accessible from outside the aircraft. Second, the engine drives the propeller directly without need for any complicated drive shafts, differentials, etc. Third, there is less volume and weight consumed by cooling apparatus. Many aircraft engines are air-cooled, and even liquid-cooled engines gain considerable efficiency from the high speed air flow.

Because aircraft design is based on weight and does not use volume, the only impact of this rule on aircraft design is to cut the final weight of such a propeller-driving engine in half. However, a designer may wish to install a propeller onto a lift vehicle, in which case the one-half volume rule would apply, which would also reduce the engine's final mass by half.

The characteristics of propellers are shown below. Propellers that are driven by turbine engine (TL-7 gas turbine or TL-8 MHD turbine) are known as turboprops.

Propellers

TL	*Th*	*MCr*	*MaxP*	*Airframe*
4	0.5	×1.5	0.6	Simple
5	0.7	×2	1.2	Fast subsonic
6	0.8	×2.5	1.4	Fast subsonic
7	0.9	×2.5	1.6	Fast subsonic
8	1.0	×2.5	2.0	Fast subsonic

TL: Tech level of first availability

Th: Thrust in tonnes per MW of power

MCr: Propellers have no price of their own, but instead increase the cost of the power plant to which they are mounted. The price of the power plant is its normal price multiplied by the value shown on the table. This price modifier is applied to the full volume of engine *before* it is cut in half for aircraft.

MaxP: Maximum power per engine.

Airframe: The fastest airframe type on which the thrust agent may be used.

Volume: Aircraft power plants used to drive propellers have their volumes multiplied by 0.5.

Mass: Propellers themselves do not alter the mass of the power plant to which they are attached. (Note however that mass is calculated based on a smaller overall volume, which will make power plants only half as massive as normal.)

HEPlaR: The other thrust agency, high efficiency plasma recombustion (HEPlaR), becomes available at tech level 10. It my be added to any power plant by adding a heat exchanger recombustion chamber to the plant. Hydrogen is injected into the recombustion chamber and the power generated by the engine heats the hydrogen to a plasma state. The plasma is then released as a high velocity stream of reaction mass, providing thrust.

HEPlaR requires a recombustion chamber of 0.1 cubic meters in volume per megawatt o power devoted to thrust, and in tun generates 20 metric tonnes of thrust per megawatt. The recombustion chamber masses 1 tonne per cubic meter of recombustion chamber and costs 0.001 million credits per megawatt of power. It consumes 0.25 cubic meters of liquid hydrogen (LHyd) per hour per megawatt of power and may be used on any type of airframe. Hull surface area (used for spacecraft only) in square meters is equal to thrust (in tonnes) + 200.

Self-Contained Thrusters: As an alternative to thrust agencies coupled to separate power plants, some power plants, such as turbojets and rockets, are much more efficient at generating direct thrust than electrical energy. These power plants have their output measured in terms of tonnes of thrust rather than MW. These plants are called self-contained thrusters.

Self-contained thrusters have auxiliary generators which generate electrical power for other systems. Generator output, in MW, is equal to thrust, in tonnes, times 0.02.

Self-Contained Thrusters

TL	Type	Th	MCr	MaxT	FC	FT	Airframe
5	Turbojet	3	0.15	6	0.5	HCD	Super
5	Ramjet	6	0.25	10	2.5	HCD	Hyper
5	LF Rocket	6	0.25	15	7.5	LRF	Hyper
5	SF Rocket	*	—	10	10.5	SRF	Hyper
6	Turbojet	3.6	0.15	6	0.25	HCD	Super
6	Afterburners	×1.5	×1.1	—	×2	HCD	—
6	Ramjet	7.5	0.30	12	2	HCD	Hyper
6	LF Rocket	7.5	0.30	1500	7.5	LRF	Hyper
6	SF Rocket	*	—	1000	9	SRF	Hyper
7	Turbofan	3.9	0.175	6	0.12	HCD	Super
7	HF Rocket	7.5	0.30	—	4.5	HRF	Hyper
7	SF Rocket	*	—	2500	7.5	SRF	Hyper
8	HBT	3	0.0625	20	0.1	HCD	Super
8	SF Rocket	—	—	5000	5.5	SRF	Hyper
8	AZHRAE (TJ)	3.6	0.50	—	0.5	HCD	Hyper
	AZHRAE (RJ)	6			2	HCD	
	AZHRAE (Rckt)	9			4.5	HRF	
9	EAPlaC	—	×2	100**	0.225	SRF	Hyper
9	Fusion Rocket	9	0.35	100**	0.00035	LHyd	Hyper

TL: Tech level of first availability

Type: Description of thruster. HBT = High Bypass Turbofan SF = solid fuel. LF = Liquid Fuel. EAPlaC = Electrothermal Augmented Plasma Combustion.

Th: Thrust, in tonnes, per cubic meter of engine.

*Note that solid fuel rockets have no engine volume *per se*; the fuel volume is the engine volume. Solid rocket fuel (SRF) mass in tonnes equals its volume in cubic meters. See FC note below to calculate solid rocket thrust.

MCr: Price, in millions of credits, per cubic meter of engine. Note that solid fuel rockets have no engine price beyond the fuel. The fuel is in effect the engine. Solid fuel costs twice its normal amount for EAPlaC engines.

MaxT: Maximum thrust, in tonnes, of a single engine. For more thrust, install multiple engines. **The values shown for the EAPlaC and fusion rockets are the *minimum* thrust ratings per engine.

FC: Fuel consumption, in tonnes, per hour per tonne of thrust. To determine volume in cubic meters, multiply by the volume of the fuel type. For solid rockets, simply pick a fuel mass. Divide the mass by the FC value. The result is thrust in tonne-hours. Select either the thrust or the duration, and the other is determined from that. For example, 18 tonnes of TL-6 SF rocket fuel could have 2 tonnes of thrust for one hour, 4 tonnes for 30 minutes, 1 tonne for two hours, or any other combination desired, as limited by the maximum allowed thrust (MaxT column).

Size Efficiency: Solid-fuel rockets with less than 500 kg of propellant (fuel) mass suffer from inefficient fuel combustion. To determine the fuel consumption inefficiency of a solid-fuel rocket, divide 500 by the fuel mass (in kilograms). The result is the final fuel use multiplier. Multiply the calculated fuel consumption of the engine by this number. However, any multiplier less than 1 is treated as 1 and any multiplier greater than 10 is treated as 10.

FT: Fuel type burned.

Fuel Volume: The volume of fuel (in m^3) used per hour per tonne of thrust is equal to the mass (in metric tonnes) consumed per hour per tonne of thrust divided by the density of the fuel, as shown below.

Type	Density
HCD (Hydrocarbon Distillates)	1
LRF (Liquid Rocket Fuel)	1
SRF (Solid Rocket Fuel)	1
HRF (Hydrogen Rocket Fuel)	.3
LHyd (Liquid Hydrogen)	.07

Airframe: Fastest airframe (for aircraft design) or chassis configuration (for vehicle design) type on which the thruster may be used. Super = Supersonic, Hyper = Hypersonic.

Mass: All self-contained thrusters mass 1 tonne per cubic meter.

Surface Area: When installed on spacecraft (only), air-breathing self contained thrusters (turbojets, turbofans, ramjets, AZHRAE) take up surface area in square meters equal to thrust in tonnes ÷100. Non-air breathers take up area equal to tonnes of thrust ÷200.

Afterburners: An afterburner (also called *reheat*) is available at tech level 6. It may be added to any turbojet or turbofan engine. When in use, it increases thrust by 50% and fuel use by 100%. An afterburner increases engine volume (and thus price and mass) by 10%.

Rockets: Rocket fuel consumption includes both fuel and oxidizer (usually liquid oxygen).

Ramjets: Ramjets must reach a speed of 800 kph before the ramjet will start. This is usually achieved either with a booster rocket, but is sometimes accomplished by carrying the aircraft aloft attached to another aircraft. This type also includes the scramjet (supersonic combustion ramjet).

AZHRAE: Advanced Zero speed to Hypersonic Regime Air-breathing Engines include a wide variety of exotic engine types designed, unlike turbine engines and ramjets, to function at low (takeoff and landing) speeds, where they function as turbojets, at hypersonic speeds for high-altitude operations, where they function as ramjets, and in suborbital/orbital insertion profiles, where they close off their intakes and function as rockets. These include

applications of such concepts as PDWE (Pulsed Detonation Wave Engines), RBCC (Rocket-Based Combined Cycle) ramjets, SER (Supercharge Ejector Ramjet), ATR (Air-Turbo-Ramjet or turbo-rocket), TSHE (Twin-Spool Hydrogen Expander) engines, and rocket fans. As a group, these are also referred to as "ducted rockets," and are the preferred engines for trans-atmospheric craft (TAC). The first AZHRAE line gives the tech level, weight, cost, airframe characteristics for the entire engine, and the thrust and fuel characteristics when operating in turbojet mode. The second line gives the thrust and fuel characteristics of the same engine when operating in ramjet mode. The third line gives the thrust and fuel characteristics in rocket mode.

Fusion Rocket: A fusion rocket is not much more than a fusion reactor with a steady stream of hydrogen going in and a hole in one end. Super-heated hydrogen plasma expelled at tremendous velocities forms the reaction mass. Because of the nature of the drive, the exhaust is extremely dangerous. It cannot be used within planetary atmospheres.

Ships passing through its hydrogen wake will generally do so quickly enough that they will not suffer any ill effects unless within very short range (~200km, referee's discretion). In this case, each crewperson must make a Difficult roll versus Constitution to avoid incapacitation by radiation (Average if wearing radiation-protective clothing) and each system on the ship suffers a minor damage result.

All crew will require blood and bone-marrow therapy over the next several months to avoid long-term health problems.

ALTERNATIVE TECHNOLOGIES

1. Realistic Thrusters

Our first alternative technology is "realistic" thrust and fuel requirements. This is not so much an alternative technology as it is the abandonment of HEPlaR thruster technology and reliance on the more primitive rocket thrusters. Even these fuel requirements have been simplified for playability, but they come much closer to duplicating the sorts of real-world design trade-offs current and near-future spacecraft designers face. While these can be used as described in the tables above, we recommend a slightly different method of calculating Gs of thrust.

Calculating Gs: Craft with the huge fuel requirements listed above require a separate mechanism for calculation of Gs, because the mass of the vessel is continually changing as fuel is consumed. As a result, thrust is measured not in Gs, but in tonnes of thrust (the thrust necessary to give 1 tonne of mass an acceleration of 1G).

Once the craft is designed, calculate its G value when fully loaded with fuel, and then calculate its G value at each 10% increment of fuel consumption. G value is calculated by dividing the thrust in tonnes by the total mass of the craft (including fuel) in tonnes. By dividing the total fuel endurance of the craft by 10, you can arrive at a useful approximation of its performance, which may, for example, be 10 minutes at 1.2Gs, 10 minutes at 1.4Gs, 10 minutes at 1.6Gs, etc.

Next, determine how much thrust in G-hours each 10% increment of fuel generates. To do so, divide the minutes of the increment (10 minutes in the example above, but it can be any length) by 60. The resulting value is multiplied by the G value of that increment to determine the total G-hours generated.

Using the example above, the increment is 10 minutes. Dividing 10 by 60 yields a value of 0.167. Therefore, the first 10-minute increment will generate 0.2004 G-hours (which we'll round down to 0.20), the second will generate 0.2338 G-hours (rounded down to 0.23), the third will generate 0.2672 G-Hours (rounded up to 0.27), etc.

The total G-hours of thrust required to reach orbit can be found by consulting the Time to Orbit table on page 225 of the basic game and looking at the Fuel G-Hrs column. Progressively, add the G-hours of thrust from each 10% fuel increment to find how much fuel is burned to reach orbit. Smaller increments of fuel (1%) can be assumed to be one-tenth of the value of a single 10% increment, rather than calculating the slight differences in thrust between the start and end of the increment.

For example, the ship above is taking off from a size 8 planet (say, Terra), and requires 0.64 G-hours to reach orbit. After the second increment, it has generated 0.43 G-hours, and does not require all 0.27 G-hours of the third increment to reach orbit. It needs 0.21, with is about 80% of the third increment. Therefore after 2.8 increments (28 minutes), the craft has reached orbit and has 2 minutes of its third fuel increment remaining.

No CG Lifters: All of the above is quite correct assuming the craft has CG lifters to negate the gravitational pull of the world and can devote all of its thrust to reaching orbital velocity. If not, part of thrust is consumed just counteracting the pull of the planet, not thrusting it up. If the craft does not have contra-grav lifters, subtract the world gravity from the thrust value of the craft when calculating its effective thrust between the surface of the world and orbit. If the craft has an airframe hull, subtract 0.5× world gravity from the thrust value. Once in orbit, ignore the effects of planetary gravity on thrust and use the 100 Diameters Travel Times and Interplanetary Speed tables (pages 225 and 227) normally.

Multiple Stages: Most rocket-propelled craft use multiple stages to reach orbit. As each stage exhausts its fuel, it is jettisoned to fall back to the planet surface. (If the planet has an atmosphere code of 4 or higher, the jettisoned stage may be recovered and reused.) Stages are numbered in the order in which they are jettisoned (thus the First Stage is the first one jettisoned).

A multiple-stage spacecraft must have its performance calculated separately for each different configuration. For example, consider a three-stage rocket. The first configuration is with all three stages and powered by the first stage engine. The second configuration is with only the second and third stages and powered by the second-stage engines. The third and final configuration is only the third stage powered by its own engine. Each of these configuration would have different gross weights, different thrusts, and thus different G ratings.

2. Ion Drives

This method of thrust is not really an alternative technology. It might better be described as a marginal technology. Ion drivers can be freely added to any **Traveller** campaign without fear of doing damage to it. They are not discussed in the main section of the rules because most games will have superior technologies which will render them superfluous. That is not to say, however, that isolated pockets of intelligent life might not be forced to use ion drives, or that even an advanced space-faring civilization might not find some use for them.

Ion drives create thrust by electrochemically reducing fuel to a stream of charged particles (ions) which creates a very low thrust. Ion engines are usually made up of a large number of very low-thrust units mounted in clusters. The advantages of these drives are

their endurance, low power requirements, and reliability. But the low thrust generated by this sort of drive limits its utility to moving low-priority cargos around inside a star system. Interplanetary trips by ion drive typically take months rather than days or weeks.

The fuels used for this system are known as "ionizates." This one term includes mercury, cesium, and a variety of liquified noble gases (argon, neon, krypton, etc.) The values given for this fuel represent an average since some of these substances would be heavier than indicated and others lighter. Ionizates are found as trace elements in most Earth-like atmospheres, but are more frequently gathered from gas giants and their moons, which sometimes boast large concentrations of noble gases.

Design: Each cubic meter of ion drive requires .03MW of power from a separate power plant and generates .003 tonnes of thrust, consuming .0000067 cubic meters of ionizates per hour. The drive masses 1 tonne and costs MCr0.013 per cubic meter of drive.

Ionizates mass 1.5 metric tonnes and cost MCr0.0001 per cubic meter.

Because of the low power requirements, ion drive ships are often equipped with large solar panels and draw on solar energy to power their drives.

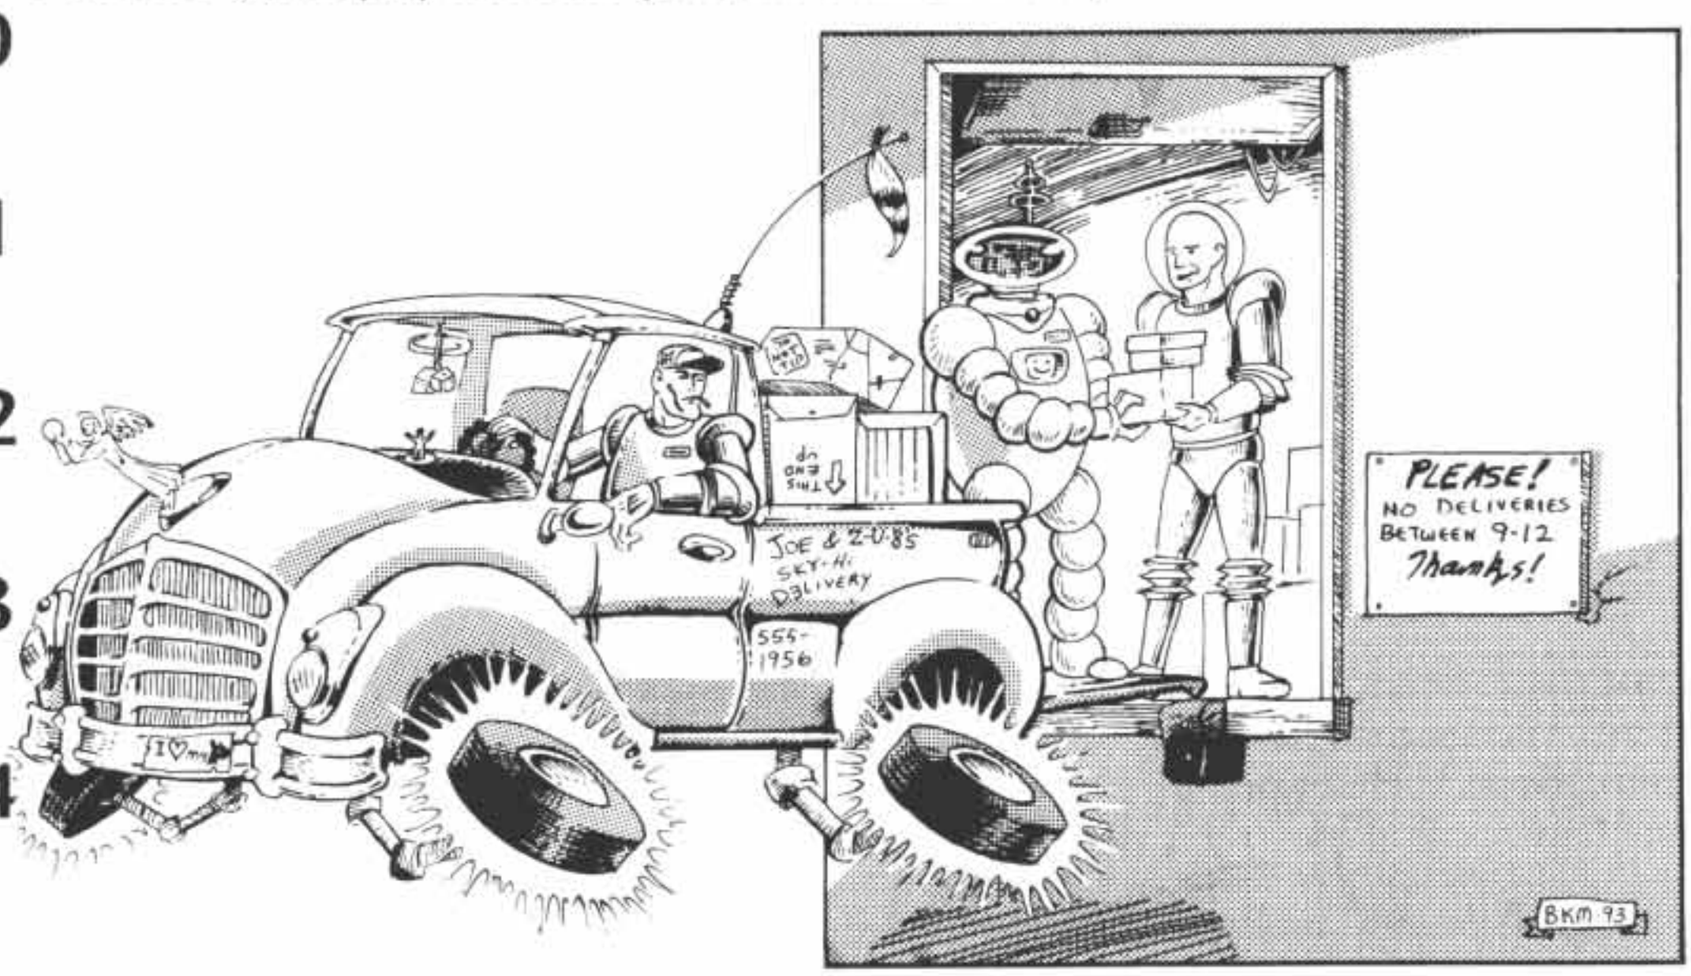
3. Dean Drive

Over 30 years ago, John W. Campbell popularized a supposed invention by a fellow named Dean. His invention, the Dean Drive, was a simple device which converted rotational momentum to linear momentum. Never mind that that violated the laws of conservation of momentum, he claimed he could do it. He wasn't able to convince the patent office, however, and never could provide a convincing public demonstration of the device, and so interest faded.

But had the drive worked, it would have had an extraordinary effect on travel, and is a perfect substitute for both CG and all thrusters. It is a reactionless means of efficiently converting electricity to thrust. The electric motor (or any other sort of engine) spins a dense shaft, thus creating rotary momentum. The Dean Drive (or, for purposes of the game, the Dean Converter) then changes this rotary momentum to linear momentum, or thrust. The standard illustration of a Dean Drive at work shows a cargo truck unloading at a second-story window, its Dean Drive converting the momentum of its drive shaft to upward momentum.

Very nice. But why does this violate conservation of momentum? Think of the solar system as a closed system spinning with a fixed average velocity. Everything in it is spinning, although at different velocities, and each of the individual bodies has angular momentum. The sum of the angular momentum of all of the individual components of the solar system equals the total angular momentum of the system.

Now, suppose something changes velocity. Assuming that its mass stays the same, its momentum changes, since momentum is a combination of mass and velocity. Does this change the total momentum in the system? No, it doesn't, because the only way things can change velocity within the system is to change the velocity of something else at the same time. Remember, "for every action there is an equal and opposite reaction." So if a rocket accelerates in one direction, reaction mass (the rocket exhaust) is accelerating in the opposite direction, and with equal force, so the net change in momentum in the system overall is exactly zero. The sum of the momentum of all the bodies in the system is still equal to exactly the same total.



But that is not true with a Dean Drive. The Dean Drive manages to change the momentum of the object it accelerates without changing the momentum of any other component of the solar system (or the galaxy, or the universe), and thus alters the total momentum in the system, hence violating the law of conservation of momentum. For the Dean Drive to work, our current understanding of the physical universe has to be seriously flawed.

On the other hand, who is to say, especially in a science-fiction game, that our understanding of the physical universe *isn't* seriously flawed? Certainly not us, and in that spirit we offer the Dean Converter as an alternative to conventional thrusters.

Design: The Dean Converter is an extremely efficient reactionless drive which requires only electric energy to operate. Each cubic meter of Dean Converter machinery converts 1 megawatt of power to 100 metric tonnes of thrust. There is no lower or upper limit on the size of Dean Converter machinery. Each cubic meter of Dean Converter machinery masses 2 metric tonnes and costs MCr0.1. Tech level of initial availability is left entirely up to the referee.

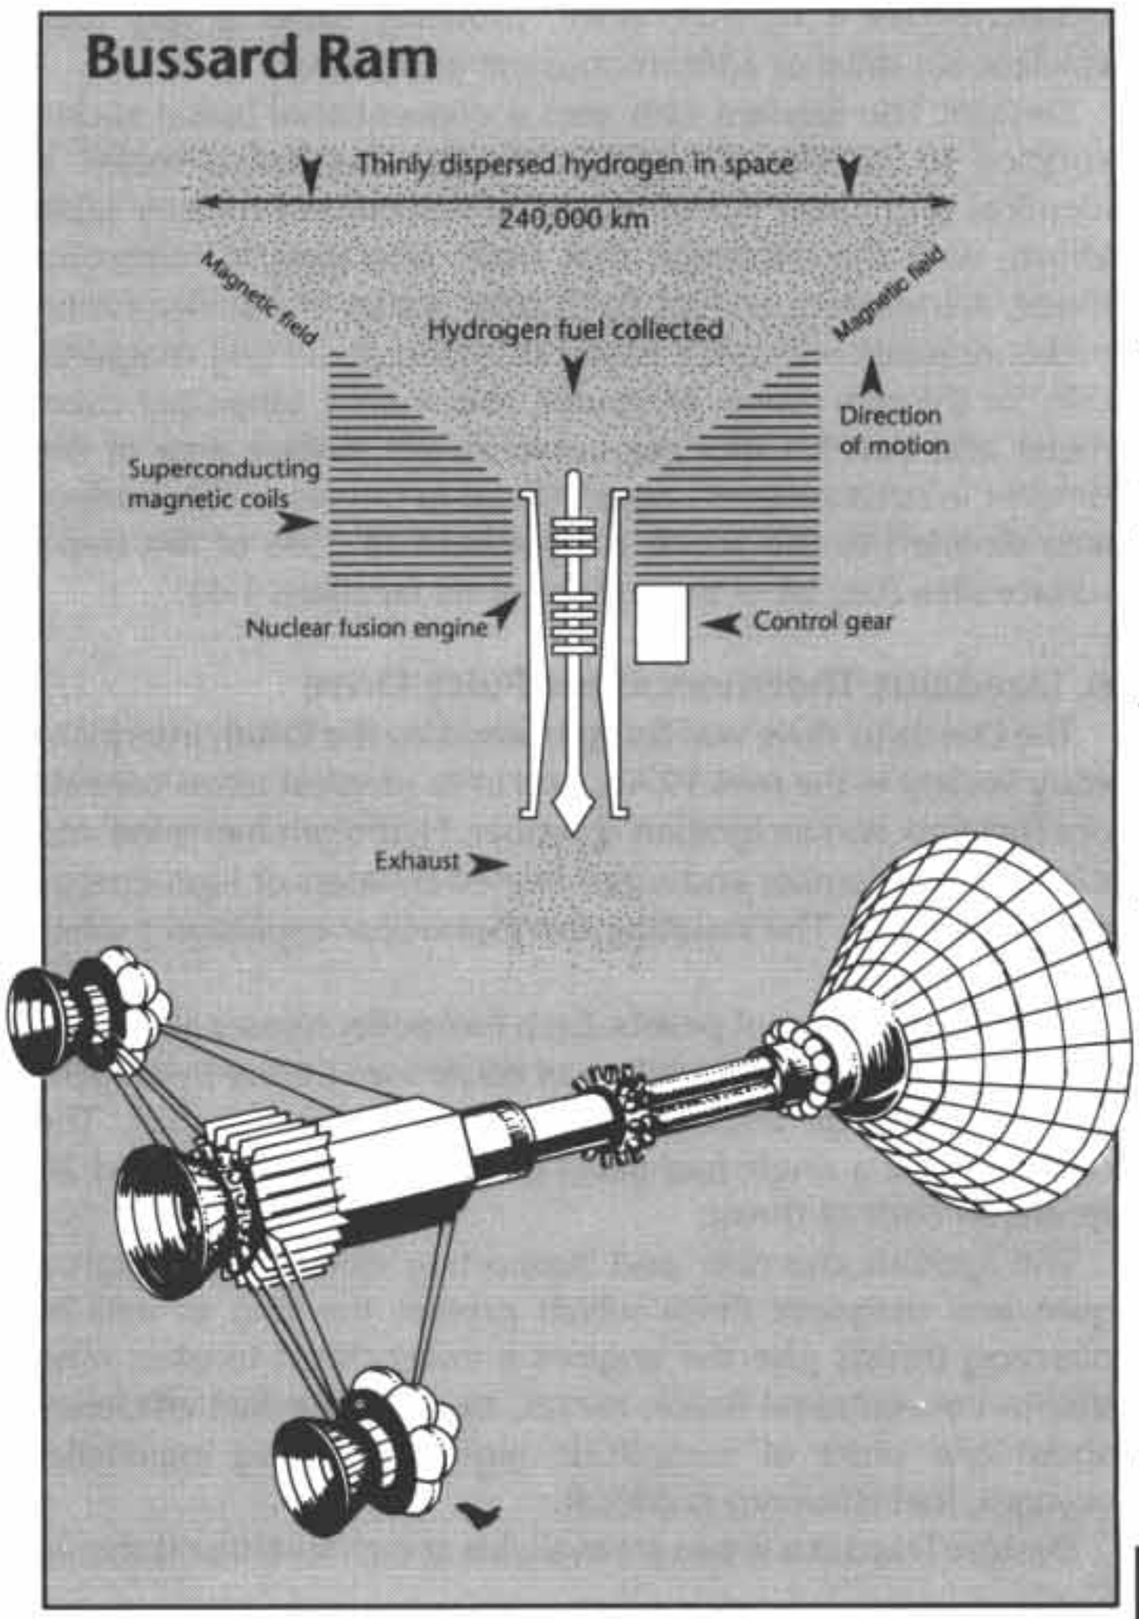
4. Thruster Plates

Maneuver drives in previous editions of **Traveller** were explained as related to the same body of theoretical physics which allowed artificial gravity and damper fields, which is to say manipulation of gravitational force and the strong nuclear force. Artificial gravity

was defined as a force which could either push or pull and which acted on the gravitational field of a mass. Clearly, this would not be an efficient means of travel outside of a gravity well, and so a further advance was postulated which allowed the force generated by the drive to push on the actual thruster plates of the ship itself, propelling it through space and achieving a true reactionless drive.

The problem with this approach is that it runs into the same wall as does the Dean Drive (see above). A drive can be reactionless without violating the law of conservation of momentum if it moves a craft around without changing its velocity. ("Huh?" No, this is not a typo. Consider the jump drive. It moves a ship from point A to point B, and does so without pushing it through the intervening space. It is a reactionless drive, but when the ship arrives at point B it has exactly the same momentum in the form of a vector as it had when it left point A. Thus, its velocity has not changed, nor has the momentum in the system overall been altered.) But a reactionless drive which changes the physical velocity of the craft shatters the law of conservation of momentum.

As indicated in the discussion of the Dean Drive, referees of science-fiction games should not be too shy about breaking the laws of physics. The *fiction* in the genre's name gives you license to do so. But the *science* in the genre's name requires you to at least know what you are doing and have a pretty good reason for doing it. In the case of reactionless drives in general, the best reason is that the sort of campaign you are running requires a cheap, efficient, no-hassle way of getting from here to there. It is best suited to campaigns with a strong space-opera flavor. (Don't sneer; those can be the most fun sometimes.)



Design: Thruster plate technology becomes available around tech level 11 (due to the fact that it is tied closely to many of the other theoretical breakthroughs that occur at about that time). Each cubic meter of installed thruster plate drive generates 40 metric tonnes of thrust, masses 2 tonnes, requires 1 MW of power, and cost MCr1. Surface area (used by spacecraft only) in square meters is equal to thrust in tonnes ÷ 200.

5. Bussard Hydrogen Ram

The Bussard ram (so called after Dr. Robert Bussard, who first proposed it in 1960) was once thought to be scientifically and technologically feasible. Greater knowledge of the workings of superconducting magnets and deuterium fusion now seem to have relegated the Bussard ram to the arena of science fantasy. Even if technologically feasible, Bussard rams are not generally used in the **Traveller** universe because jump drives make them irrelevant. This is because Bussard rams are drives designed to bridge the distance between stars at sublight velocities.

The biggest single problem in tackling interstellar distances is fuel. You have plenty of distance between stars in which to accelerate and get up to really healthy fractions of light speed, but as hard as it is to find room for several G-hours of acceleration, imagine trying to carry several G-*years* of fuel—then imagine slowing back down.

The Bussard ram beats this problem by using the thin interstellar atmosphere for fuel. What atmosphere, you say? You thought space was a vacuum? Well, for most purposes it is. There is insufficient atmosphere to have any measurable pressure, but

there is the odd hydrogen atom floating around. The problem is gathering enough of "the odd hydrogen atoms" (one or two atoms per cubic centimeter of space) to constitute useful fuel for a hydrogen fusion rocket.

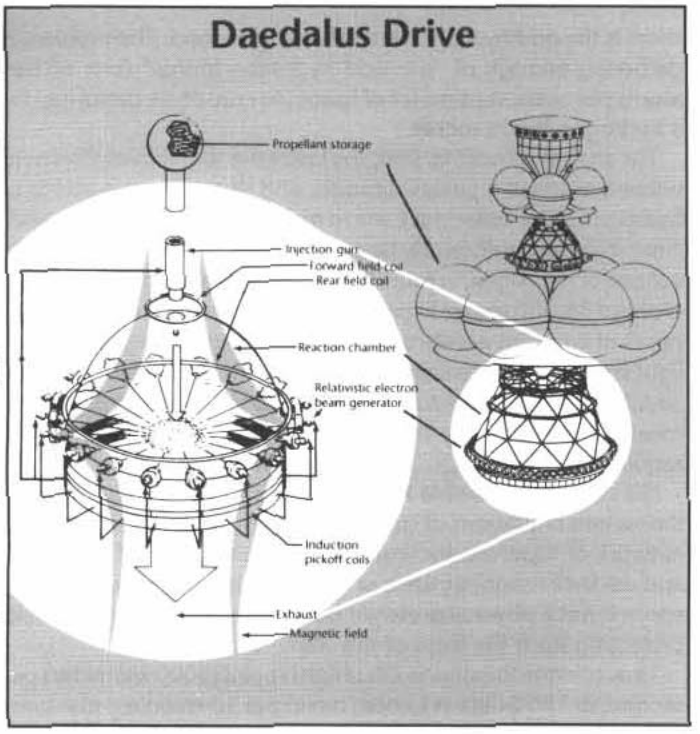
The answer is twofold. First, the faster the ship moves, the more volume of space it passes through, and thus the more atoms of hydrogen it can collect for fuel in a given amount of time. Second, if the ship has a sufficiently large fuel scoop, it can gather a larger volume of hydrogen. In round numbers, a ship needs a scoop area of about 35,000 square kilometers per metric tonne of ship's mass per G of constant acceleration, and needs to reach about 1% of light speed before it is scooping enough hydrogen for the ram to sustain a continuous fusion reaction. By way of illustration, this means that a fairly tiny ship, of about 1000 tonnes mass, would require a scoop over 2000 kilometers in diameter.

It is clearly not feasible to build a solid scoop that large, given the weight limitations of the craft. The answer is instead to use a network of superconducting magnets as the base of the scoop and use their magnetic fields as the scoop itself. That is, the ship's scoop is not a physical presence but rather a large magnetic field projecting from the front of the ship.

To accelerate the ship to 1% of light speed (3000 kilometers per second, or 180 **Brilliant Lances** hexes per 30-minute game turn)

would require a separate drive, probably either a very fuel-efficient ion drive or a thermonuclear pulse drive.

Design: The Bussard ram uses a conventional fusion rocket coupled to an electromagnetic scoop. The fusion rocket is identical to the one noted on the self-contained thruster table above, with the exception that while operating in ramscoop mode, it consumes no fuel. Each cubic meter of installed fusion rocket requires one cubic meter of superconducting magnetic coils for the ram scoop. Magnetic coils mass 1 tonne per cubic meter and cost MCr0.5 per cubic meter. Surface area of the thruster in square meters equals thrust in tonnes + 200. Surface area devoted to the scoop is equivalent to 25% of the ship's surface area (i.e., all of the surface of hit locations 1-5).



6. Daedalus Thermonuclear Pulse Drive

The Daedalus drive was first proposed by the British Interplanetary Society in the mid-1970s, and in its simplest terms consists of a fuel tank and an ignition chamber. Hydrogen fuel is fed into the ignition chamber and super-heated by lasers or high-energy electron beams. The resulting thermonuclear explosion pushes the ship forward.

Fuel is in the form of pellets. Each fuel pellet masses about 1.5 grams and consists of a mixture of deuterium (heavy hydrogen) and helium-3, all enclosed in a superconducting shell. The detonation of a single fuel pellet produces between 15 and 20 tonne/seconds of thrust.

The ignition chamber and supporting electronics (electron guns and magnetic fields which protect the ship as well as directing thrust) give the engines a lower thrust-to-mass ratio than a conventional fusion rocket, but provide fuel efficiency about one order of magnitude higher. For long interstellar voyages, fuel efficiency is critical.

Design: Daedalus drives are available at tech level 9 and above. Each cubic meter of engine masses 1 tonne, generates 1.5 tonnes of thrust, and consumes 0.0005 tonnes of fuel per hour. Price is MCr0.5 per cubic meter of engine. Surface area of the ignition chamber in square meters is equal to tonnes of thrust + 200. Because of the exacting manufacturing requirements, fuel for the Daedalus drive costs 100 times as much as conventional hydrogen fuel.

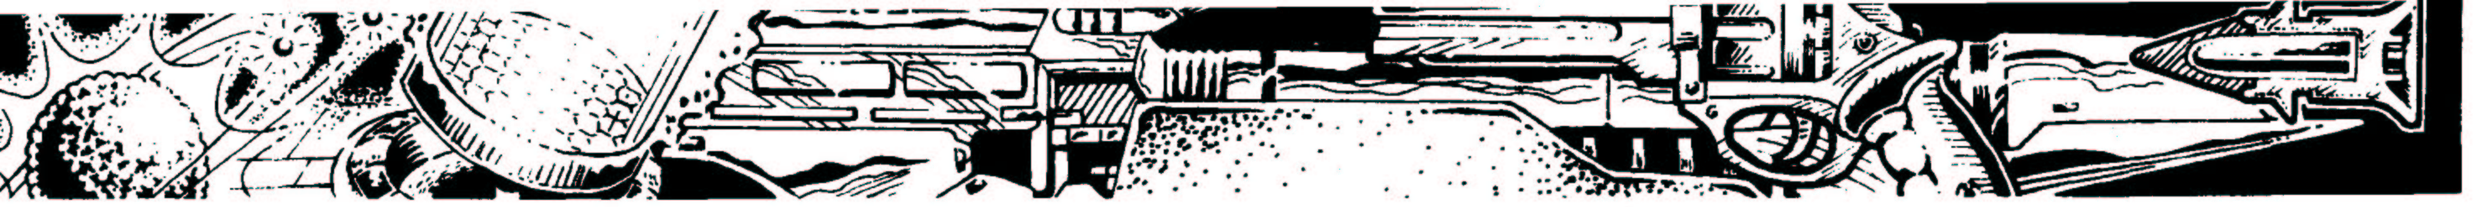
7. Solar Sails

Solar sails are extremely leisurely ways of moving around in a solar system. Solar sails are extremely large, lightweight reflective surfaces which rely on the physical pressure of photons in sunlight for thrust.

The almost-universal first instinctive reaction to solar sailing is that the sail can only carry the craft away from the sun, but in fact the sail can be used to tack (to borrow a yachtsman's term) and use thrust to move back toward the sun. How is this possible?

The solar sail is not a stationary object with straight-line vectors. As it is an object in the solar system, it is in orbit (although it may be a very distant orbit) around the sun. As the sail can be angled, it can be used to either add to the orbital velocity or decrease orbital velocity. As orbital velocity increases, the sail assumes an orbit farther away from the sun, and so moves away from it. As orbital velocity decreases, however, the sail assumes a closer orbit and so actually moves toward it. In both cases, however, movement is gradual due to the extremely low thrust generated by the sail.

The pressure of sunlight on the sail inside the habitable zone of a star system generates 0.5 kg of thrust (or 0.0005 tonnes) per square kilometer of sail. As a square kilometer of solar sail, complete with its rigging, weighs 0.5 tonnes, or 1000 times as much as the thrust generated, and that is without any payload, it is immediately obvious that the sail generates minute acceleration. However, that minute acceleration is constant and free (with respect to fuel), and so is very economical for long voyages if you aren't in any particular hurry.



To calculate G-hours of thrust generated by the sail, divide the total mass of the spacecraft (including the mass of the sail) by the sail's thrust in tonnes (square kilometers of sail area multiplied by 0.0005). The result is the number of hours of acceleration needed to achieve one G-hour of acceleration.

Thrust is multiplied by 10 in the star's inner zone and by 0.01 in the star's outer zone.

Solar Sails

TL	*Mass*	*MCr*
8	0.5	.001
9	0.4	.0005
10	0.3	.0004
12	0.2	.0003
14	0.1	.0002
16	0.05	.0001

TL: Tech level of first availability.
Mass: Mass, in tonnes, per square kilometer of sail surface.
MCr: Price, in millions of credits, per square kilometer of sail surface.
Vol: Stored volume of 1 square kilometer of solar sail is 10 cubic meters.

CHAPTER 10
Lifters

By lifters we mean unconventional methods of levitating a craft (conventional means including lifting gasses, airframes, rotors, and conventional thrusters). The standard lifter used in **Traveller** is the contra-gravity device found on most spacecraft. Several alternative lifters are described later in the chapter.

It should be noted that two other alternative lifter technologies—the Dean Drive and thruster plates—are included in the Sublight Drive chapter (Section 9) as they are also useful for interplanetary travel.

Contra-Grav

Many spacecraft have contra-grav (CG) lifters as fuel-efficient means of landing and taking off from a planet surface, and CG lifters are also used on grav vehicles. CG lifters do not provide thrust and so cannot physically lift a craft or vehicle. Instead, they neutralize most of the gravitational attraction of a world (approximately 99% of gravitational force, beyond which power use becomes prohibitive). This, combined with atmospheric pressure, will provide buoyancy in very dense atmospheres and so allow the craft to float at low altitudes, but usually CG is used only as an adjunct to the ship's thrusters. By neutralizing most of a world's gravitational field, a ship with only 1G of thrust can still escape the world's gravity well.

Note that CG does not reduce the mass of the ship, and so a 1G thruster will still only produce 1G of acceleration; CG merely negates the gravitational vector of a world.

Surface area below (used for starships only) includes space for landing gear/skids.

Contra-Grav Lifters

Type	*TL*	*MW*	*Kl*	*Mass*	*MCr*	*Min Vol*
Standard	9	0.3	0.5	0.4	.02	1
Improved	10	0.2	0.3	0.3	.025	0.3
High Efficiency	12	0.1	0.3	0.2	.03	0.03

TL: Tech level available.

MW: Power requirement per displacement ton (14 kl) of hull.

Kl: Volume, in kiloliters (cubic meters), per displacement ton (14 kl) of hull.

Mass: Mass, in tonnes, per displacement ton (14 kl) of hull.

MCr: Price, in millions of credits, per displacement ton (14 kl) of hull.

Min Vol: Smallest installation volume allowed.

Surface Area: 10% of total hull surface area, used for spacecraft only. Surface area is not calculated separately for lift vehicles, as it is subsumed into their standard surface area calculation.

ALTERNATIVE TECHNOLOGIES

1. Ducted Fans

Although ducted fans are currently capable of lifting small payloads, the technology presented below relies on material breakthroughs that allow much stronger fan blades as well as some minor bending of aerodynamic laws.

Ducted fan lifters work on principles similar to those used by helicopters. Instead of a single (or sometimes twin) large-diameter rotor, however, ducted fan craft have a larger number of smaller multiple-blade propellers, almost identical to turbine fans, imbedded in the craft's hull. These high-speed fans suck air in from overhead intakes and vent it beneath the craft, providing lift. The power plant also injects fuel directly into the air flow and combusts it, effectively turning the fan assemblies into very large diameter turbofans. As with helicopters some of this lift can be vented for thrust.

Because of the ability to angle atmosphere flow inward from the ducts along the outer edges of the vehicle, ducted fan lifters create a ground effect cushion directly under the vehicle when operating at very low altitude (less than four or five meters), and it is at these altitudes that ducted fan craft are most efficient. Above these altitudes, lift declines dramatically and increasing amounts of engine thrust have to be switched to lift instead of thrust.

Design: Ducted fan technology becomes available at tech level 8, when light composites make stronger fan blades possible. The thrust characteristics of ducted fan assemblies are shown below. Thrust generated by ducted fans may be devoted to either lift or lateral thrust (and may be switched from one to the other during flight). Speed is calculated based on lateral thrust. Thrust devoted to lift must be equal to the mass of the vehicle. All thrust devoted to lift at NOE altitude, however, produces double lift. That is, each tonne of thrust produces 2 tonnes of lift.

Characteristics of ducted fan assemblies are shown below.

TL	*Thrust*	*MCr*
8	1	0.5
10	1.5	0.4
12	2	0.3
14	2.5	0.2

TL: Tech level of first availability.

Thrust: Thrust, in tonnes, is equal to the power plant output devoted to thrust, in megawatts, multiplied by the value shown on the table.

MCr: Price, in millions of credits, per cubic meter of fan assembly.

Vol: Volume, in cubic meters, is equal to the power plant output in megawatts devoted to the ducted fan multiplied by 0.5.

Mass: Mass of the fan assembly in tonnes is equal to its volume in cubic meters.

willis teal (order #936741)

Afterburn: All ducted fans have the ability to inject fuel and burn it in the air stream, which works similar to the afterburner on a jet. This doubles fuel use for the power plant and increases thrust by 50%. Afterburners are generally used only at high altitudes or for bursts of speed.

2. Maglev

Current magnetic levitation (maglev) research is concentrated on making near-frictionless trains, which ride on (or actually over) magnetized rails. This is not what we are talking about here, however. Maglev here is defined as a means of free levitation by riding the magnetic field of a planet. One obvious limitation of this form of lifter is that it is useless on a world which does not have a magnetic field, or which has a very weak one.

Aside from the fact that they function only in a strong magnetic field, maglev lifters are built and function in the same way as CG lifters.

Maglev Lifters

TL	*MW*	*Kl*	*MCr*
10	0.3	0.5	.02

14	0.2	0.3	.03
16	0.15	0.25	.035
18	0.1	0.2	.04
20	0.05	0.1	.05

TL: Tech level available.

MW: Power requirement, in megawatts, per displacement ton (14 kl) of hull.

Kl: Volume, in kiloliters (cubic meters), per displacement ton (14 kl) of hull.

Mass: Mass, in tonnes, is equal to volume in cubic meters.

MCr: Price, in millions of credits, per displacement ton (14 kl) of hull.

3. Gravitic Displacement

The contra-grav lifters described in the game are far from the only imaginable means of manipulating gravity, and of the various types imaginable, one of the more interesting we cal a gravitic displacement (GD) field. A GD field displaces the potential energy of a mass toward the closest gravity source without moving the mass itself, thus circumventing gravity with respect to the physical mass. This allows a massive objec to rise and hover, and has much the same effect as contra-grav The technical requirement of GD fields are similar enough to those of contra-grav that the same design procedure can be used. The only important difference is in the actual operation of the lifters.

Since a GD field displaces the potential energy of a mass toward the nearest gravity field, GD lifters have to be used with great care. A ship massing 1000 tonnes and hovering at a dozen meters or so will have the same effect on the ground surface directly beneath it as if it were resting physically on the ground. Light structures, plant life, and animal life alike would be crushed.

Craft at higher altitudes cause less surface disruption as their potential mass is spread over a wider area, but there are strict altitude and traffic regulations for even small craft flying near metropolitan areas. Large craft have very rigidly controlled landing and takeoff patterns, and these are over water whenever possible. (The ship will make a huge depression in the surface as it pulls over the water at low altitude.)

Grav vehicles, such as grav tanks, can again make crushing overrun attacks on enemy personnel, but pressure-sensitive mines (some of which are angled to fire charges directly up at the belly of grav vehicles) will also be triggered by their passing. In short, GD lifters are identical in gross effect to CG lifters, but add a number of interesting additional detailed interactions with a planet surface.

CHAPTER 11
Life Support

Spacecraft, high-altitude aircraft, and all vehicles intended for use in a hostile environment require some sort of life support equipment. Specific design sequences provide guidance on minimum required levels of life support.

Life Support Equipment

Oxygen tanks and masks allow breathing at high altitudes or in a hostile atmosphere. Overpressure consists of a compressor and filter for use on worlds with tainted atmospheres or in a chemical, biological, or radiologically contaminated environment. It draws air in, filters any contaminants out of it, and pumps it into the craft at a higher pressure level than the outside. This allows an unsealed vehicle to remain contaminant free, as there is a constant flow of air outward, preventing contaminated air from entering.

All powered vehicles include some form of heating and internal lighting.

Basic life support provides sealed environment, air, and water. Extended life support adds waste disposal/recycling and food, and is required for all craft that are operated for 8+ hours at a time, or vehicles in a hostile environment intended to operate for a day or more away from base. Craft with extended life support substitute this for basic life support.

The most common types of life support are shown on the table below.

LIFE SUPPORT EQUIPMENT

TL	Description	MW	Vol	Mass	MCr
5	Air Lock	0.001	3.000	0.200	0.005
5	Oxy. Tanks & Masks	—	0.010	0.010	0.0001
5	Overpressure	—	0.001	0.001	0.0001
5	Basic Life Support	0.0001	0.005	0.005	0.0003
6	Extended Life Spt.	0.0002	0.008	0.008	0.0005
8	G Tanks (pass)	—	2	2	0.01
8	G Tanks (crew)	—	2	2	1
10	Artificial Gravity/ G Compensators*	0.005	0.010	0.020	0.0005

TL: The tech level of availability.

MW: The energy requirement, in millions of watts, per cubic meter of enclosed hull volume (except that the requirement listed for air locks is per installed air lock).

Vol: The volume of life support equipment, in cubic meters, per cubic meter of enclosed hull volume (except that the requirement listed for air locks is per installed air lock and for oxygen tanks and masks is per passenger and crewperson).

Mass: The mass of life support equipment, in tonnes, per cubic meter of enclosed hull volume (except that the requirement listed for air locks is per installed air lock and for oxygen tanks and masks is per passenger and crewperson).

MCr: The price of life support equipment, in millions of credits, per cubic meter of enclosed hull volume (except that the requirement listed for air locks is per installed air lock and for oxygen tanks and masks is per passenger and crewperson).

Aircraft: For aircraft, the enclosed hull volume, in cubic meters, for purposes of life support requirements, is defined as the total number of passengers and crew multiplied by 2.

Airlocks: The minimum number of airlocks required on a spacecraft is equal to the hull number (displacement in tons) divided by 100, rounding all fractions up. Each air lock requires 2 square meters of hull surface area.

G Compensation

Ships with a G rating greater than 1 may only use the acceleration for limited periods of time, unless they have G compensators or G tanks installed. (Prolonged periods of high acceleration will otherwise injure the crew.)

G tanks are large fluid-filled tanks that passengers and crew are immersed in during high-G maneuvers. As crew workstations require secure means of interacting with controls and monitors while immersed, crew (workstation) G tanks are extremely expensive.

Artificial gravity G compensators create an artificial gravity field in direct opposition to the axis of acceleration, thus negating the acceleration (up to the limit of the artificial gravity field). Compensated Gs is the number of acceleration or evasion Gs negated by the compensator. The amount of Gs which can be compensated vary by tech level as shown on the table below.

All crews can automatically withstand 1G, so the maximum acceleration without degrading crew performance is actually 1G above this level, as shown in the Max Accel column to the left of the slash. Evasion Gs, however, are applied erratically, and so cannot be withstood by crews without degrading performance, as shown in the Max Evade column to the left of the slash. Beyond these levels, all tasks are performed at one difficulty level higher (+1 Diff Mod) per G-turn applied.

Starship crewmembers who are strapped into workstations (for **Traveller** space combat, this is assumed to be everyone except damage control parties, maintenance crew, stewards, medics, and ship's troops) can withstand 1G additional of acceleration or evasion before their performance is degraded. These figures are shown to the right of the slash in the Max Accel and Max Evade columns.

G tanks always compensate 1G and all passengers and crew in -tanks are treated as strapped into a workstation (and so use that column). Note that damage control parties cannot use G tanks while working, and so such a ship may only accelerate at 1G while making repairs and may not evade at all.

TL	Compensated Gs	Max Accel/ Workstation	Max Evade/ Workstation
10	1G	2G/3G	1G/2G
11	2G	3G/4G	2G/3G
12	3G	4G/5G	3G/4G
13	4G	5G/6G	4G/5G
14	5G	6G/7G	5G/6G
15	6G	7G/8G	6G/7G
16	7G	8G/9G	7G/8G
18	8G	9G/10G	8G/9G
20	9G	10G/11G	9G/10G

Extended Accommodations

Craft which will house passengers and crew for more than 24 hours require extended accommodations. Passengers and crew require bunks for short trips of several days, provided they understand that accommodations are to be austere. Staterooms are required for paying passengers. Each High Passage passenger requires one stateroom (large or small). Middle Passage passengers require one stateroom (large or small) in the Regency, but are placed two to a large stateroom in the Wilds (never two to a small).

Civilian crew are usually accommodated two to a large stateroom, or one to a small stateroom in the case of officers.

Military crew are usually accommodated at best like civilian crews, but will often be carried at double occupancy (two per small, four per large stateroom) or greater, or even housed in bunks. Bunks may be multiple-occupied by "hot bunking," by sleeping in three shifts per 24-hour period.

Officers will not sleep in bunks, nor accept worse than double occupancy.

All values on the table below are per installation.

EXTENDED ACCOMMODATIONS

Description	*MW*	*Vol*	*Mass*	*MCr*
Bunk	—	14	0.5	.005
Low Berth	0.001	14	1.0	.05
Emergency Low Berth (for 4)	0.002	28	2.0	.1
Small Stateroom	0.0005	28	2.0	.04
Large Stateroom	0.001	56	4.0	.1

Environmental Gravity

On trips lasting longer than one week, the absence of gravity in deep space will begin to have harmful physiological effects, principal among them being loss of muscle tone and, eventually, loss of bone calcium. Regular exercise can only reduce these effects, it cannot prevent them. Prevention requires some form of artificial gravity. Ships equipped with artificial gravity generators (covered above under G compensators) automatically have a steady 1G environment. Ships without grav compensators must instead generate gravity by means of spin.

Ships which rely on spin habitatsto provide gravity do not have to spin the entire vessel (although sometimes this is done). Instead, only that part of the vessel occupied by accommodations need be spun.

There are several varieties of spin habitats, broken into the following general categories. The several designs of spin habitats are differentiated more for purposes of deck plans than for the particulars of design. The requirements for volume and additional machinery actually vary very little between most of these. Their descriptions should help visualize your ship during design.

Spun Hull: This is the simplest, but usually largest, spin habitat. In it, the hull is a large cylinder that spins around its long axis, thus providing centrifugal gravity in the outer part of the cylinder. Due to Coriolis effects, the central part of the cylinder (within a radius of 10 meters) is unusable for quarters or workstations, and thus is usually used for fuel, cargo, and low-maintenance machinery. More often the hull is built like a doughnut, and the central core is left empty. The basic game's lab ship is an example of a ship built in this configuration.

Only open structures and cylinder hullforms may use this type of spin habitat.

No additional machinery is required for a spun hull.

Double Hull: In this design, the outer hull spins but surrounds an enclosed inner hull which does not. Again, this design is most useful for very large ships as the enclosed central hull is at least 10 meters in radius.

Only cylinder hullform ships may use this type of spin habitat.

Double hulls require a volume of machinery equal to 1% of the enclosed volume of the *outer* hull. Mass is 1 metric tonne per cubic meter and price is MCr0.001 per cubic meter.

Hamster Cage: The hamster cage consists of a cylindrical module that is at 13 meters in radius, and that spins to create artificial gravity. Unlike other designs, the hamster cage is often set at right angles to the axis of the ship and generally installed in counter-rotating pairs (to eliminate torque effects on the ship's attitude).

Any ship hullform may use hamster cages, but the ship may not have an airframe configuration.

Hamster cages require a volume of machinery equal to 1% of the enclosed volume of the modules. Mass is 1 metric tonne per cubic meter and price is MCr0.001 per cubic meter.

Spin Capsule: The most common spin habitat in use is the spin capsule. In this design, two or more quarters modules of the desired size are placed at the ends of pylons that rotate around a common axis. (Usually, but not always, this is also the long axis of the ship). The spin capsules have a rotational radius of at least 10 meters. Access to the capsules is by way of the pylons, which contain ladders or powered lifts. Power and atmosphere is also supplied through the pylons.

All spin capsules are designed to retract against the ship's hull during violent maneuvers or atmospheric travel, and so any hullform and configuration can have spin capsules.

Spin capsules require a volume of machinery equal to 5 percent of the enclosed volume of the capsules. Mass is 1 metric tonne per cubic meter and price is MCr0.001 per cubic meter.

Two Body: Two ships can attach themselves together using a pylon and spin around a central point to provide gravity. The chief disadvantages of this design are that both ships must be present in order to spin and neither ship may maneuver or change vectors while linked.

All that is required for a two-body spin habitat (aside from the two ships) is a pylon made of hull material (hard steel or a material of greater hardness) that is at least 1% of the combined mass of the two ships. Volume and price are determined by the material used to construct the pylon.

Custom Life Support Design

Fuel tankage volume does not require life support or artificial gravity. However, without these, the tankage is more difficult to repair and maintain, and cannot be used for emergency or expedient measures (such as the installation of modular quarters).

CHAPTER 12
Cybernetics

The core **Traveller** universe does not concentrate heavily on cybernetic enhancements. Although there is no reason not to include this sort of technology in an on-going campaign, its effects on both the style and substance of play are so powerful as to completely dominate the game. Therefore, referees should give some serious thought to the sort of game they wish to run before deciding on how much cybernetics will be used.

The Imperial Space campaign will not be dominated by cybernetic issues, but will deal with these issues only on the level that they provide futuristic "realism."

Cybernetics is the science of electronic, mechanical, and biological enhancement of living organisms. Its most primitive antecedents are the peg legs and hooks used to replace missing legs and hands, inferior substitutes for the originals. Engineering advances made prosthetic limbs progressively more effective replacements for missing body parts, until eventually the replacements became superior to the original organic component.

Once elective cybernetic enhancement becomes a reality, each society has to face a number of ethical issues which are not easily resolved, and which invariably turn separate societies in different directions. Some embrace cybernetic enhancement whole-heartedly, others reject it completely, and still others find an uneasy middle ground. How a particular society reacts to cybernetic enhancement is up to the referee, but is an issue which should be considered carefully before cybernetics are incorporated into a campaign.

Virtually all societies view cybernetically enhanced humans in different terms than "natural" humans, and a wide variety of slang (some derogatory) inevitably grows up to help define that difference. The most common slang for a cybernetically enhanced human is "ironman" (or "iron maiden"), while unenhanced humans are called "slicks." By the same token, cybernetic enhancements which are visually indistinguishable from original organic components are called "slickware," as opposed to hardware or cyberware.

As general rule, it is a good policy to impose some penalty on visible cybernetic enhancements, usually to a player's Charisma attribute, and usually amounting to a –1 per visible cybernetic modification.

A typical outline progress of cybernetics by tech level is shown on the following table.

TL	*Type*
5	Primitive prosthetics (artificial limbs)
6	Reconstructive surgery
7	Advanced plastic surgery
8	Full-function prosthetics
9	Direct brain-machine interface allows prosthetic eyes and ears and neural jacks. Early controlled chemical manipulation of body systems
10	Enhanced-performance prosthetics and subdermal armor
11	Direct computer implantation
12	Advanced chemical manipulation of body systems
13	Genetic manipulation, enhancement, and replacement of selected tissues

A wide variety of cybernetic modifications and enhancements are discused below. These are broken into four broad categories: head jobs, body implants, peripherals, and therapy.

Head jobs, as the name suggests, have to do with cybernetic modifications to the character's head, usually to the principal sensory organs (eyes and ears).

Body implants include large systems which cannot easily be fit into the head and which are instead mounted in the abdominal or thoracic cavity, sometimes replacing or displacing internal organs.

Peripherals are modifications to the arms and legs, either for improved performance or adaptation of limbs to special functions.

Therapy consists of organic modification of the character's body, either through drugs, genetic manipulation, or surgical procedures.

Power

Many of the cybernetic enhancements detailed require the input of electrical power to function. This power is produced in one of two ways.

Items that need only small amounts of power, such as various passive sensor eyes, are powered by tiny thermoelectric generators that produce the needed electrical power from body heat. These generators are subsumed within the volume, weight, and price of the item.

Other items, particularly those which transmit energy (active sensors and radio or video transmitters) and enhance strength, have thermoelectric power supplemented by tiny long-life batteries, also subsumed within the volume, weight, and price of the item. These batteries must be periodically recharged by a specialized adaptor which can convert standard current into a form suitable to the batteries.

Some systems require no power at all. These systems are completely passive, as in the case of subdermal armor, completely biological, as in the case of aquatic skin, or have their mechanical functions connected to the host's muscles, which operate the mechanism as if it were any normal skeletal component, as in the case of the hard hand. All of the respiratory implants are treated as being completely biological, even though they may include the insertion of various synthetic components.

Head Jobs

Head jobs all require delicate surgery to the head, and most deal with very sensitive nerve connections. These procedures can be extremely dangerous if not done properly, and so they tend to be the most expensive of the cybernetic enhancements.

Cyber Eyes: Direct electronic/nerve interface at tech level 9 opens the way for a wide variety of cybernetic enhancements to eyesight. Early cyber eyes are single-function eyes, and are easily recognizable as mechanical implants, but at higher tech levels a wider variety of functions are available and they become less obvious.

The following table shows the general development of cyber eyes over time. In all cases, the cyber eye includes basic visible light vision, and the table indicates the number of additional features which can be added. A dash indiactes that a cyber eye is not available at that tech level and a "0" indicates that no extra function can be added to basic visible light spectrum vision. Note that some additional options count as more than one feature for purposes of the capacity of the eye.

"Hard" eyes are immediately recognizable as cybernetic enhancements, while "slick" eyes appear normal to casual observers.

	Functions	
TL	*Hard*	*Slick*
9	0	—
10	1	—
11	2	0
12	3	1
13	4	2
14	5	3
15	6	4
16	7	5
17	8	6
18	9	7
19	10	8
20	11	9

A number of options available for cyber eyes are listed below. In all cases, skill tests to detect objects using cyber eyes are made with the Observation asset.

Telescopic: Telescopic vision allows magnification similar to a telescope or binoculars, with zoom controlled by eyeball pressure (which is manipulated by squinting).

Active Infrared: A beam of infrared light is projected either from forehead-mounted lights (in the hard version) or through the eye itself (in slick versions). Active infrared is a useful sensor at night, but will not penetrate smoke, dense fog, blowing sand, etc. It has a short range of 60 meters. Slick active IR eyes are sufficiently bulky that they count as two options instead of only one.

Passive Infrared: The eye is extremely sensitive to infrared radiation and can "see" heat. Most living creatures and machines have very distinct heat signatures, while inanimate objects can usually be seen by the amount of heat that they absorb from the sun. Nevertheless, objects after sundown which have completely cooled off become almost invisible to passive IR. Unlike active IR, passive IR can see through most smoke and blown dust, but is rendered ineffective by rain or snow. It has a short range of 30 meters.

Star Eyes: Star eyes use light-amplification techniques to allow normal vision in low light conditions (primarily nighttime using starlight, hence the name). Smoke, blown sand, and any sort of atmospheric conditions will interfere with star eyes. They have a short range of 120 meters. Star eyes are sufficiently bulky that they count as two options instead of only one.

Color Enhancement: Color enhancement, originally developed to aid color-blind patients, is useful for resolving detail at long distances and for detecting camouflage. Color hue and intensity is adjusted by increasing or decreasing eyeball pressure. (This can be accomplished by squinting.) Color enhancement is useless in limited-visibility situations. For purposes of detecting camouflage, color enhancement has a short range of 120 meters.

High-Resolution Thermal (HRT): HRT is an advanced form of passive infrared with a short range of 300 meters. HRT can see clearly through most forms of smoke, but has its performance cut in half by rain or snow. HRT eyes are sufficiently bulky that they count as two options instead of only one.

Imaging Radar: The eye contains a millimeter wave radar transmitter and processor unit with fine enough resolution for image formation. Imaging radar has a short range of 300 meters and is not degraded by any atmospheric effects. Imaging radar is sufficiently bulky that it counts as three options instead of only one.

Image Enhancement: Image enhancement not only magnifies but also sharpens focus and contrast, making visual recognition easier. Image enhancement has the combined effects of telescopic vision and star eyes. Image-enhancement eyes are sufficiently bulky that they count as two options instead of only one.

Wide-Spectrum Visual (WSV): This eye combines magnification and image enhancement with sensitivity to light across a broad spectrum, from ultraviolet through infrared. As such, it combines most of the advantages of earlier sensor eyes in a single package. Its short range is 300 meters. WSV is sufficiently bulky that it counts as three options instead of only one.

Target Link: Only characters with a neural jack may use a target-linked eye, and only with weapons designed for target interface (so-called "smart" weapons). The weapon's bore sensor, when engaged, projects a target image in the middle of the user's vision field, showing what the weapon "sees" rather than the actual image. An alternative shows a distinct colored line along the weapon's line of fire if the line of fire is within the user's field of vision, and a colored arrow prompt showing what direction to look to find the line if it is out of the user's field of vision. This line is invisible to anyone else, since it exists only inside the user's eye.

Any small arm or heavy weapon may be modified by the addition of a "smart sight." Available at TL 10, it has a volume of 1.5 liters, masses 0.2 kilograms, and costs Cr5000. The smart sight also has the features of an electronic sight (see page 97).

Recorder: This option allows the user to make a one-hour video recording and play it back at a later time. The recording can be transferred to hard video by means of a small laser viewer that fits over the eye. The video image on the organic recording will begin to deteriorate after 48 hours. The recorder feature is sufficiently bulky that it counts as three options instead of only one.

Holo-Recorder: As the recorder described above, but the recording is a three-dimensional hologram. The holo-recorder feature is sufficiently bulky that it counts as four options instead of only one.

Eyeball Display: This allows projection of information in readable form in the user's field of vision, much like the heads-up display of a fighter aircraft. It is particularly useful if a computer implant is used, but can is also useful with chronometer or inertial navigation implants.

Rangefinder: This option may only be installed if the user also has an eyeball display. The rangefinder projects a low-energy infrared laser beam and determines range from the reflection. It is accurate to within 1% of range out to 5 kilometers.

Cyber Ears: Cybernetic augmentation of hearing is available considerably sooner than is visual augmentation. Early cyber ears are simple amplifiers, often worn externally, which are later replaced by implants inside the hearing canal, all but invisible. At higher tech levels, a wider variety of functions are available.

The following table shows the general development of cyber ears over time. In all cases, the cyber ear includes basic hearing, and the table indicates the number of additional features which can be added. A dash indiactes that a cyber ear is not available at that tech level and a "0" indicates that no extra function can be added to basic hearing.

"Hard" ears are immediately recognizable as cybernetic enhancements, while "slick" ears appear normal to casual observers.

	Functions	
TL	*Hard*	*Slick*
6	0	—
8	1	0
10	2	1
12	4	2
14	5	3
16	6	4
18	7	5
20	8	6

A number of options available for cyber ears are listed below.

Amplified: This allows amplified hearing and clear audio resolution of faint sounds at distances of 100 meters or more.

Low Frequency: This allows hearing of low-frequency sounds, sounds which are more often felt or sensed than heard. Hearing these sounds makes it easier to pinpoint the direction of origin. Early versions of this ear tend to be oversized.

High Frequency: This option allows a person to hear sounds above the aural range of normal humans. Early versions of this ear tend to be made from very dense material, such as plastic or even metal.

Sound Dampening: Although loud or irritating sounds won't damage bionic ears, they can be annoying, distracting, or even painful to the user. This option enables the owner to dampen out specific ranges from the sonic spectrum, allowing sound to be dampened, which can also make it easier to hear a specific sound (such as a human voice) in a noisy environment.

Recorder: This option allows the user to record one hour of sound and play it back at a later time. The recording can be accessed at any point and can be recorded over.

Sonar: Sonar ears may only be used in conjunction with a computer implant. An omnidirectional variable-tone ultrasound transmitter in the ear sends out ultrasound waves and then determines distance to the nearest objects by means of echo-ranging. A continuous low tone in the ear when the system is engaged provides information to the user as to range based on pitch and volume of the tone. If an eyeball display is available, the sonar can also build up an ultrasound map of the space around the user and overlay it on the visual image of the eye. If only one ear is installed, the head must be moved around to build up a full sonar map. If both ears have sonar features, no such "scanning" is necessary.

Comm Receiver: Communicators are normally too bulky to install in the ear itself, but the speaker for the communicator is generally located there. See the Body Implants section (page 82) for details of communicators available.

Eye-Ear Combination Suite: This is a special cybernetic combination suite available at tech level 10 and higher. It is available as a hard option only and replaces both the eye and ear on one side with a clearly visible synthetic housing. No attempt at cosmetic disguise is made. The suite allows the standard number of hard options for the eye and ear plus two additional options added to either, or split between them. Cost is the sum of the options selected, but the suite lowers Charisma by 4 instead of the normal 2 (1 each for a replacement eye and ear).

Other Options: A number of other head options are available, some of which can be used in conjunction with options already covered.

Neural Jack: This is a socket, usually mounted in the temple or (for cosmetic reasons) at the base of the neck, and is used to establish direct electronic contact between the human brain and electronic equipment. It allows the brain to receive and decode electronic data as well as transmit commands directly to linked equipment.

When "jacked in" to machinery, all tasks using that machinery become one level easier. When jacked in to memory bank and educational programs, the Education attribute is increased by 3.

Chronometer: This is an installed day, date, and elapsed time recorder linked to an eyeball display.

Inertial Navigation System: This is an installed inertial positioning and navigation system. A eyeball display must be installed for this option to be used. The navigation system will display current magnetic bearing and will also show the bearing to any of five previously recorded positions.

Psionic Shield: This serves the same function as a psionic shield helmet, but is permanently built in (and usually undetectable).

Power Jaw: This option involves complete replacement of the upper and lower jaw and teeth with synthetic material. Strength is mechanically enhanced which allows the user to bite through a variety of materials and inflict 1D6 hits if used to bite a hostile character.

Jaws of Death: This is a hardware-only option consisting of oversized jaws with enlarged teeth (so-called "jaws of death") which allows the user to use them to make armed melee attacks in the same way as do large predators. Jaws of death inflict 2D6 hits, but cause a –2 CHR penalty due to their (deliberately) grotesque appearance.

Subdermal Armor: This option surgically layers thin synthetic armor protection below the skin surface but over the skull.

The following table summarizes the important information concerning cybernetic head modifications.

Cyber Head Options

TL	Type	Number of Spaces	MCr
9/11	Visible Spectrum Eye	0	0.01
10/12	Telescopic Eye	1	0.01
10/14	Active IR Eye	1 or 2	0.03
11/14	Passive IR Eye	1	0.05
12/14	Star Eye	2	0.10
12/13	Color Enhancement Eye	1	0.005
13/16	Imaging Radar Eye	3	2.0
14/16	HRT Eye	2	0.1
14/16	Image Enhancement Eye	2	0.1
15/18	WSV Eye	3	0.5
10/11	Target Link Eye	1	0.01
11/12	Eyeball Display	1	0.01
11/15	Rangefinder Eye	2	0.02
12/16	Recorder Eye	3	0.05
14/18	Holo-Recorder Eye	4	1.0

11/12	Chronometer	—	0.0001
11/12	Inertial Nav	—	0.001
13/14	Psionic Shield	—	0.04
9/11	Power Jaw (1D6 damage)	—	0.005
9/—	Jaws of Death (2D6 damage)	—	0.01
10/11	Subdermal Armor AV (1)	—	0.25
12/13	Subdermal Armor AV 0 (2)	—	0.2
14/15	Subdermal Armor AV 1	—	0.2
17/18	Subdermal Armor AV 2	—	0.15

TL: Tech level of first availability. The first number is the tech level at which the feature is available as a hard option, the second the level at which it is available as a slick option.

Number of Spaces: The number of features the particular option counts as when determining the total capacity of the cyber eye or ear.

MCr: The price, in millions of credits, per feature, at the tech level of introduction. This price is halved at all higher tech levels. Note, however, that slick options cost the full printed price at their first tech level of availability, even though hard options of the same sort are by then less expensive.

Body Implants

Larger systems cannot usually be fit inside the skull and so are placed in the thoracic or abdominal cavity, usually anchored to the skeleton, and sometimes replacing part or all of an organ. Body implants include four general areas: respiratory implants, electronics, dermal alteration, and computer implants.

Respiratory Implants: These devices deal with respiration and affect the ability of the user to function under physical stress of in a hostile environment.

Supercharger: This is a device used to store some of the endorphins that the character's body naturally produces. The endorphin is saved for reintroduction into the body when needed to add extra oxygen to, and remove fatigue toxins from, the character's bloodstream. The supercharger is installed in a space made available by removal of half of a kidney. A supercharger increases a characters CON attribute by 2. No more than one supercharger may be installed.

Hypercharger: A larger and more advanced form of the supercharger, the hypercharger requires removal of an entire kidney and increases a character's CON attribute by 3. No more than one hypercharger may be installed, and it may not be installed in addition to a supercharger.

Filter Lungs: Filter lungs implant filters and scrubbers in the character's lungs which allow breathing of tainted atmosphere without harmful effects. Early versions rely on extensive pre-lung filters (mostly near the surface, and physically replacing the nose). When this version is installed, the users have to blow their "noses" frequently while operating in hostile environments to clear the filters.

"Slick" versions use filters and scrubbers actually in the lung. The impurities scrubbed from the air are flushed through the normal body waste system, but can strain the system severely. Characters must have both kidneys intact to use slick filter lungs and should drink large quantities of fluids while in a hostile environment.

Gill Implants: Gill implants allow the character to extract oxygen from water. Gil implants usually require enlargement of the thoracic cavity, and the gills themselves are clearly visible on the user's neck. "Slick" versions of the gill implant place the gill slits on the sides of the ribcage and reduce the amount of thoracic cavity increase by use of a hypercharger. (The hypercharger is not included in the price of the implant and must be installed separately.)

Electronics: The following items include communicators and sensors too bulky to emplace in the skull.

Radio Communicator: Communicators are generally attached to the spine and linked to the speaker and/or microphone in the head by means of the spinal cord. The earliest radio communicators are receivers only and are limited to a single band. Multiband receivers soon become available followed by transmitter/receivers of varying power.

Video Transmitter: Video transmitters are available one tech level after audio radio transmitters for twice the price of an audio transmitter of the same range. For example, a hardware 30-kilometer video transmitter is first available at tech level 13 and costs MCr0.02. Use of this transmitter requires either a recorder eye or a camera jacked into the transmitter.

Neural Activity Sensor (NAS): Neural activity sensors are an outgrowth of the same technology that permits electronic psionic shields. They detect and classify life forms according to the level of brain activity, but are extremely short-ranged. NAS requires an eyeball display.

Dermal Alterations: The following options deal with modifications to the user's skin. Some of these are all-body modifications (meaning they include modifications to the limbs and head as well), but they are included here for the sake of simplicity.

Aquatic Skin: Aquatic skin involves chemical and genetic alteration of the outer skin to a form resembling that of marine mammals (such as dolphins and whales), which allows prolonged immersion in water without need for a protective wet suit. Aquatic skin must be kept moist at all times, however, or it will begin to dry and crack, and the user will begin to suffer symptoms of severe dehydration within two or three days, usually dying within a week if access to water is continually denied.

Vac Skin: Vac skin is synthetically grown skin which is permeable at normal pressure differences but becomes non-permeable at pressure differences approaching 1 atmosphere. This allows characters to function in vacuum with only a breathing helmet and some sort of personal heating/cooling system.

Subdermal Thoracic Armor: This option surgically layers thin synthetic armor protection below the skin surface but over the ribcage. It covers the chest only. The hard (as opposed to slick) version of this armor is not only more noticeable, but it is also heavier. As a result, hardware versions of thoracic armor lower the CON attribute by 1.

Subdermal Abdominal Armor: This option surgically layers thin synthetic armor protection below the skin surface. Given the absence of a rigid bone structure to anchor the armor to, abdominal armor is inherently less effective than thoracic armor. The hard (as opposed to slick) version of this armor is not only more noticeable, but it is also heavier. As a result, hardware versions of thoracic armor lower the CON attribute by 1.

The following table summarizes the important information concerning the above cybernetic body implants.

Body Implant Options

TL	*Type*	*MCr*
—/11	Supercharger	0.030
—/12	Hypercharger	0.040
9/11	Filter Lungs	0.200

Computer Implants: Beginning at tech level 12, it is possible to have a computer surgically implanted and cybernetically linked to the conscious brain centers. The lightest of these computers still mass one kilogram and so are too large to implant in the skull. Instead, the computer consists of a series of a half-dozen or more small subcomponents which are fused to individual vertebrae of the spine (on the inner sides) in such a way that they do not interfere with articulation. They are linked to each other and the organic brain by way of the spinal cord. Output from the computer can be accessed either by way of an eyeball display, an in-ear speaker, or direct machine-brain interface, if the user also has a neural jack installed.

Computer implants serve several functions:

First, some cybernetic systems require a computer implant to achieve their full potential. For example, a cybernetic sensor suite consisting of an HRT eye and an amplified hearing ear, when linked to a computer implant, will allow a character to determine the emotional state of the person they are conversing with and have a reasonable chance (80%) of determining if they are lying or telling the truth.

Second, and assuming the character has a neural jack, implant computers can substitute for regular computers on a limited basis. While they are not powerful enough to carry out all functions of a larger computer of the same type, they allow the player to conduct specific tasks one at a time. For example, a character's implant computer cannot replace the general systems diagnostic function of a ship's computer (which reduces the maintenance requirements of the ship), but it can allow the character to calculate jump parameters, or run a master fire director, of pilot the ship through the atmosphere for a landing.

Third, it allows the character to store background and technical information for later recall. The character can query the computer about specific information during an adventure and receive a reply. Since memory in the computer is not infinite, the referee must impose some limits on the information available. Very general questions (such as basic questions about physical laws and the outline history of the Imperium) will almost always be answerable by the computer. Specific questions about local history or a scientific specialization will be answered only 40% of the time. Very specific questions about individuals, recent discoveries, or obscure historical facts (and assuming that the referee considers the computer implant to have ever had access to this information) will be available only 20% of the time.

Before an adventure begins, however, characters should be allowed to pick one or more subjects and optimize the computer's data base around that subject. This doubles the chances the question will be answered by the computer (40% becomes 80%, 20% becomes 40%) but reduces the chance of an off-topic question being answered by 10% (40% becomes 30%, 20% becomes 10%).

The number of subjects a character can select is equal to the computer model number minus 6. In other words, a Model 10M computer can be optimized for four subjects. If the number of subjects chosen for optimization is half or less of the total allowed number of subjects, the off-topic penalty is not suffered.

Virus: If cybernetics are added to an Imperial Space campaign, one recurring hazard of a computer implant is that it may become infected with Virus. Only implanted computers of model 10M and higher are powerful enough to serve as a host for Virus, although any computer can be a carrier.

Since the computer is permanently jacked into the character's conscious brain, a viable infection by Virus is potentially fatal to the character. However, some strains of Virus will cause the implanted computer to become self-aware but not necessarily homicidal or suicidal, and may just give it a bizarre personality. The nature of the infection and its effects are up to the referee, but assuming that an infected implant computer has some similarities to a robot brain, referees are directed to the discussion of sentient robots on page 98 of the basic game rules for guidance.

Implant Computers

TL	*Mod*	*Wt (tonnes)*	*MCr*
12	7M	.001	0.5
13	8M	.001	0.4
14	9M	.001	0.4
15	10M	.0012	0.6
16	11M	.0014	1.0
17	12M	.0016	1.2
18	13M	.0018	1.8
19	14M	.0016	2.4
20	15M	.0014	3.0
21	16M	.0012	4.5

Model "M" computers are micro-computers suitable for implantation.

Peripherals (Arms and Legs)

Peripherals are modifications to the arms and legs, either for improved performance or adaptation of limbs to special functions.

Upper Limbs: These cybernetic modifications are to the arms and hands, mostly the hands.

Chainsaw Hand: This attachment is a 30-cm chainsaw, useful for light construction work and brush clearing and a devastating melee weapon. There is no slick version of this attachment. Attacks with a chainsaw hand count as armed melee attacks.

Grapple Hand: This hand can be fired up to 20 meters in any direction, connected to the user's arm by means of a length of fine but extremely strong cable, capable of holding 200 kg of weight safely, 400 kg if attached to a cyber utility arm). The hand contains 50 meters of cable (100 meters if attached to a utility arm) which can be reeled in or out at will. The hand can function as a grappling hook wherever there is a handhold capable of supporting it, and can be used to descend as well as ascend. The user does not have fine manipulative control of the hand while it is extended at the end of the cable, but can close and open the hand at will to grasp or release handholds.

Hand Socket: A hand socket allows the character to use a variety of different cyber hands. If a character does not have a hand socket, then whatever cyber hand is chosen is permanently mounted to the hand. If a hand socket is mounted, then any socket hands may be used.

Any cyber hand option may be purchased as a socket hand by increasing the price by 50%. Hand sockets may be installed on organic arms; utility arms come with hand sockets already installed and are included in the price.

Hardfist: This is a cybernetic replacement hand with specially reinforced bones and heavy knuckles, allowing the character to deliver much more powerful blows. Melee strikes delivered with a hardfist do double damage.

Movement of the fingers is somewhat restricted by the modifications. Tasks performed using the hand which rely on agility are performed with a –1 modification to the character's Agility attribute.

Knuckle Blades: Knuckle blades can be added to a cybernetic hand or an organic hand. The telescoping 10-cm blades are normally retracted into sheaths in the back of the hand, but when the fist is clenched in a particular manner the blades emerge from their sheaths out from over the knuckles.

Movement of the hand is somewhat restricted by the modifications. Tasks performed using the hand which rely on agility are performed with a –1 modification to the character's AGL attribute.

Pistol Hand: This hand is built around a small automatic pistol. Hard (as opposed to slick) versions of the hand do not have functioning fingers. Slick versions have working fingers and thumb, although the index finger is rigid.

The actual pistol is designed using the small arms design sequence, but with several limitations on the design. Hard versions may not have a weight greater than one kilogram (including ammunition). Soft versions may not have a weight greater than 0.4 kilograms (including ammunition), and may not have a bore diameter greater than 7.5mm. The design must include the weight of a pistol grip, although this component is shaped like the hand, not a conventional pistol grip.

The price listed below for the pistol hand is for the attachment equipment and frame only. The design price of the installed pistol is added to this.

Power Hand: This hand has up to 10 times the normal gripping strength, but retains the normal sensitivity of the human hand. While this does not allow the character to lift any greater loads, it enables him or her to exert crushing pressure on objects and to lock the hand in place, thus allowing the character to hang suspended for long periods of time without suffering fatigue. (The character may even sleep while the hand is locked in place.)

Protected Cyber Components: Arms and hands completely replaced by cybernetic prosthetics are considerably easier to armor. In order to use the ratings for protected cybernetic components, a character must have a utility arm (see below).

Subdermal Armor: Given the limited space available, it is extremely difficult to add effective subdermal armor to the hand and arm. This is reflected in the fairly low protection levels available. In addition, hard (as opposed to slick) subdermal armor lowers the character's AGL attribute by 1.

Tentacle Hand: On this hand, the thumb and fingers functions normally but can be telescoped to form tentacles up to three meters in length. Each tentacle has the strength of a normal human hand, and the hand can be used for climbing, grappling, reaching through small openings, and hundreds of other uses.

Movement of the fingers when the tentacles are retracted is somewhat restricted by the modifications. Tasks performed using the hand which rely on agility are performed with a –1 modification to the character's AGL attribute. When extended, the tentacles do not suffer this penalty.

Torch Hand: This hand is an electric cutting/welding torch incorporating an internal battery which contains power enough for two minutes of operation. Thirty seconds of use is regained for every six hours of recharging. Hard versions of the hand do not have movable fingers and cannot be used as conventional hands, but slick versions do and can.

Torque Hand: This hand is capable of rotating at high speed in either direction on its socket, and the fingers can be locked in place to grip small objects securely, making the hand useful as a torque wrench. When not used as a torque device, the hand functions normally.

Utility Arm: This is a standard cybernetic replacement for a human arm, originally developed as a prosthetic replacement for limbs lost due to injuries. It mimics the function of a human arm extremely well, suffering some loss in sensitivity but making up for that with greater strength. All tasks performed exclusively or primarily with a cybernetic utility arm are done with an attribute modification of –1 to AGL and +2 to STR.

The arm is equipped with a human analog hand, but the hand is mounted in a socket and can be removed and replaced with other options. The arm also has a small hidden compartment in which documents or small objects can be concealed.

Legs: The following replacements and enhancements for legs are available.

Power Legs: Power legs are complete cybernetic replacement legs with power enhancement and shock absorbers. Power legs allow the character to conduct tasks as if the character's strength was 16, provided the task relies solely on the legs. This usually involves lifting objects (provided the character can lock his or her back and rely solely on legs to lift it), or forcing open doors (again by bracing the character's back and relying solely on leg power). Power legs also allow the character to leap four meters straight up in 1G (and proportionately more or less in different gravity fields) and jump down twice that distance without injury.

Characters with hard power legs may not run; then may only trot. Characters with slick power legs may run normally.

Speed Legs: Speed legs increase the character's running speed from 30 meters per turn to 50 meters per turn.

Dynalegs: Dynalegs combine the effects of power legs with those of speed legs. Hard (as opposed to slick) versions do not have the prohibition on running that normally accompanies hard power legs.

Subdermal (SD) Armor: Given the limited space available, it is extremely difficult to add effective subdermal armor to the leg. This is reflected in the fairly low protection levels available.

Protected Cyber Component (PCC) Armor: Legs completely replaced by cybernetic prosthetics are considerably easier to armor. In order to use the ratings for protected cybernetic components, a character must have either power or speed legs.

1 2 3 4 5 6 7 8 9 10 11 12 13 14

The following table summarizes the important information concerning the above cybernetic peripherals.

Melee Effects

Several peripheral attachments have melee effects, some counting as armed and some as unarmed attacks. Hit Mods are added to character's asset.

Unarmed Melee Attacks

Type	*Attack*	*Hit Mod*	*DV*
Hardfist	Hand Strike	—	×2
Tentacle Hand	Grapple/Strangle	+2	×2
Power Legs	Kick	+2	×2

Armed Melee Attacks

Type	*Range*	*Hit Mod*	*DV*
Knuckle Blade	Short	+2	1D6+(STR+2)
Chainsaw Hand	Short	—	2D6+STR
Power Hand	Short	—	2D6+STR
Torch Hand	Short	—	3D6

Therapy

Therapy consists of organic modification of the character's body, either through drugs, genetic manipulation, or surgical procedures.

Muscle Implants: This technique involves taking a muscle tissue sample from the character, cloning it, then grafting these new muscles into the existing tendon/ligament system of the character. The technique will increase a character's STR attribute by up to 6, but for every point of strength gained the character will temporarily lose 1D6 points from the AGL attribute until the character is used to working with the additional muscle mass. Characters regain lost AGL attribute points by expending experience points, just as if improving a skill rating.

Installing muscle implants is time-consuming, demanding one month of physical inactivity from the patient. It is also expensive, costing Cr12,000 per point of Strength gained. Available at TL 10+.

Tesseron Beta: This is a drug that stimulates the endocrine system, causing increased production of strength-producing hormones. It is administered in a weekly dose and must be taken continually to keep up its effect. When a character first takes T-Beta, there is no immediate effect.

With the second dose (the second week of the therapy), the character must make a Difficult test against CON to avoid violent muscle contractions. If the test fails, the character suffers 1 hit to each body part and must discontinue the therapy. If the test is successful, the character may continue the therapy without further risk of mishap.

With the third dose (the third week of therapy), the character will gain from 1 to 3 points of STR (1D6+2, rounding fractions up). This added Strength level will remain in effect so long as the T-Beta treatment is continued. Once it is terminated, the STR attribute declines by 1 point per week until it reaches its original pre-therapy level. At the same time, T-Beta withdrawal will also cause an AGL decline of 1 point per week, due to muscle twitches, until STR reaches its original level. After that, AGL will increase by 1 point per week until it reaches its original level.

T-Beta prices vary. Typical costs are 1D6×Cr50. Available at TL 9+.

Neural Sheathing: This technique utilizes viruses which have been engineered to manufacture and deposit certain organic chemicals around the nerve fibers of a character. The plastic-like sheath decreases the electrical resistance of the nerves and various outside electrochemical interferences to neural communication. To perform the process, a doctor takes samples of blood, nerve tissue, and spinal fluid from the patient and determines what support chemicals are required for the virus to perform properly. The process must be monitored for one full month, with a medical appointment every three days to update the support solution.

The doctor must make a successful Average task roll using Diagnosis as an asset for the procedure to succeed. If the task roll fails, the procedure is not successful, but may be attempted again later. If the task roll is a Catastrophic Failure, the process cannot be retried and the character permanently loses 1 point from the AGL attribute due to induced nerve hypersensitivity.

If the procedure is successful, the character's AGL attribute is increased by from 1 to 3 points (1D6+2, rounded up). The price of the treatment is Cr30,000. Available at TL 11+.

Vassopressin-Y: This drug allows the human brain to modify its electrical pathways, which will make it easier for a character to learn new things and recall things already learned. Due to its addictive effect, this drug is usually used by people who are beginning major projects (preparation for a special mission, for example) and can quit after the project's completion. The drug must be taken in daily doses for two full weeks for any effect to occur, at which time the character's INT attribute is increased by 1D6 points.

If the character remains on the drug for a month or less, there are no side effects. For every month thereafter that the character remains on the drug, the character's Willpower skill is reduced by 1 (regained at a rate of 1 point per week after Vassopressin-Y is no longer taken). Characters whose Willpower is reduced to 0 (or who suffer a Willpower reduction when they have no Willpower skill to begin with) slip into a catatonic state for 1D6 weeks and then recover.

In order to voluntarily terminate Vassopressin-Y therapy, a character must make a successful roll for an Average task using Willpower as an asset. This roll is made once per day at the time the normal dose would be taken. A character must be successful on each of seven consecutive days for the addiction to be broken.

The price for a daily dose of the drug on any given world is Cr3D6. Available at TL 12+.

CHAPTER 13
Teleportation

Matter transporters make use of the same principles of tunneling that are used in most FTL drives, but do so on a micro instead of macro level. Most teleporters are short range (less than 10,000 kilometers) and handle comparatively small masses (tonnes, as opposed to hundreds of tonnes).

Teleporters require only a transmitter, not a transmitter and receiver, the main facility serving both functions. That is, it can teleport objects from its own location to a distant target or it can teleport objects from a distant target to its own location. Although only the one teleporter is required, one endpoint of the operation must be the machine itself.

Objects being teleported have vectors which must be dealt with during the teleportation process. For example, an object in space has its vector of travel which will probably be quite different from that of the teletransmitter it is being teleported into. Even "stationary" objects on a world's surface have vectors: a vector toward the center of the world due to gravity (also called "potential energy"), and a lateral vector tangential to the world's surface caused by planetary rotation. Both of these vectors will vary with altitude.

In order for objects arriving at the teleported destination to not go crashing through a wall or floor, their vectors must be adjusted to match those of their destinations (although this need not be done if this is the effect that the teleporter operator is seeking). The energy required to do this (or the excess energy released in doing this) is subsumed into the boost energy calculated below. The homopolar generators which form part of the teleporter also serve as sinks or reservoirs for the energy consumed or released by this vector adjustment.

In order to "teleport in" an object (i.e., pick it out of space and bring it to the teleporter), the teleporter must be hooked into a system (such as a starship or ground installation) which has a target lock on the object to be teleported. At the long ranges available at TL 19 and 20, this target lock will usually be obtained by another sensor closer to the target which is "handed off" to the teleporter, usually via tight-link communicators. In some cases, a "teleporter booth" is constructed which is simply a passive sensor which locks onto the booth's contents and hands off that lock to the teleporter some distance away, which then plucks out those contents.

As a practical limit, without FTL communicators (see Section 5), TL 21 teleporters can only be used to "teleport out" objects at their maximum range, as it would require faster-than-light communications to receive the target lock hand off necessary to teleport in an object from a parsec away. There is one exception to this, which is a pre-arranged pick-up from a site carefully surveyed in advance and fed into the teleporter's controls. This of course requires that the teleporter have absolutely perfect data on all of the variables of this pick-up site, such as a world's orbital and rotational data, diameter, topology, etc., in the case of a site on a planetary surface.

All teleporters must also be hooked into a full-size computer (model St or Fb) of the same tech level.

Teleporter performance is defined by several critical characteristics.

Range: The maximum range of the teleporter in kilometers at that tech level.

Volume: The cubic meters of teleporter machinery required per metric tonne of capacity. In other words, if a designer wishes to build a teleporter of seven metric tonnes capacity and at that tech level the volume requirement is four, the teleporter would require 28 cubic meters of machinery.

Boost Energy: This is the amount of energy required per tonne/kilometer to teleport an object. To determine the total energy required, multiply the mass (in tonnes) of the object to be teleported by the distance (in kilometers) it is to be teleported by the boost energy value.

HPGs: In addition to teleporter machinery, a teleporter must have homopolar generators installed, and the peak power of the homopolar generators is the upper limit on teleporter performance. For example, even if a teleporter is built with sufficient capacity to teleport 20 tonnes of mass and is of a tech level capable of teleporting it 1,000,000 kilometers, if the homopolar generators are not large enough to provide the necessary boost energy then it cannot achieve that level of performance.

The homopolar generators also serve as potential energy reservoirs and sinks for vector adjustment.

Teleporters

TL	*Range*	*Vol*	*Boost*
18	2500	5	4
19	2,500,000	4	2
20	200 AUs	3	0.5
21	1 Parsec	2	0.001

TL: Tech level of availability.

Range: Maximum range of teleporters at this tech level. 200 AUs is approximately 2.5 billion kilometers. 1 parsec is approximately 2.5 trillion kilometers.

Vol: Volume of teleporter machinery, in cubic meters, per metric tonne of transfer capacity.

Boost: The energy, in millions of joules (MJ), required per kilometer/tonne to teleport an object.

Mass: The mass of the teleporter, in metric tonnes, is equal to the volume of its machinery in cubic meters.

Price: The price of the teleporter, in millions of credits, is equal to the volume of its machinery in cubic meters multiplied by 200.

CHAPTER 14
Fire Control

Fire control equipment is designed to assist weapons in hitting a target. A wide variety of fire control equipment is available to cover the range of weapons included in the game. In general, fire control equipment is used for heavy and vehicle-mounted weapons. The equivalents of fire control equipment for small arms are called sights and are included in the actual design sequences for the weapons.

DIRECT FIRE CONTROL

Direct fire control is used by projectile weapons (CPR guns and electromagnetic mass drivers) and high-energy weapons (plasma and fusion guns). Both fire an amount of high-speed matter—on the one hand a slug of metal, on the other a slug of plasma—at their targets. Since either way the projectile is unguided, the actual target solution obtained before firing is the critical element in successfully hitting the target.

Two types of fire control equipment are available to help make this target solution. The first type is called sights and rangefinders, since most primitive sights either have some form of rangefinder on them or are calibrated for different ranges. All direct fire projectile weapons must have a sight/rangefinder.

The second type is a ballistic computer. This device allows the gunner to incorporate corrections for target movement, atmospheric conditions, tilt of the firing weapon, and so forth, thus negating difficulty modifiers to the to-hit task. Ballistic computers are optional, but are usually added to larger weapons.

Point Defense: Ballistic computers may also be modified to serve as point-defense computers. Point-defense computers are used to enable a weapon system to shoot down incoming bombs and artillery projectiles. A ballistic computer may be modified as a point-defense ballistic computer by doubling its mass, volume, and price.

Point-defense computers function the same as an unmodified computer of that tech level except when firing at ballistic projectiles. Ballistic projectiles are those which are not maneuvering and are following a fixed trajectory (such as an artillery round, a bomb, or an unguided missile or rocket). When a weapon equipped with a point-defense computer fires at ballistic projectile, the projectile's speed modifier is halved (rounding fractions down).

1. Sights and Rangefinders

TL	*Type*	*Range*	*Mass*	*MCr*
4	Iron Sight	0.2	.005	.00025
5	Telescopic Sight	0.4	.01	.0005
6	Optic Rangefinder (RF)	0.6	.02	.001
7	Laser RF	0.8	.04	.005
8	Imaging Radar	1.6	.06	.01
10	EMS RF	3	.08	.02

TL: Tech level of first availability.
Range: Upper limit on short range in kilometers.
Mass: Mass in tonnes.
MCr: Price in millions of credits.
Vol: Volume in cubic meters is equal to mass in tonnes.

2. Ballistic Computers

TL	*Type*	*Mass*	*MCr*	*Diff Mod*
6	Analog	0.01	.002	1
8	Digital	0.02	.005	2
10	Digital	0.04	.02	3
12	Digital	0.04	.1	4
14	Synaptic	0.03	.5	5
16	Synaptic	0.02	1	6
18	Fluidic	0.02	2	7

TL: Tech level of first availability
Mass: Mass in metric tonnes
MCr: Price in millions of credits
Diff Mod: Number of increases in difficulty ignored.
Note: Ballistic computers may be purchased from one tech level higher than level of manufacture of the weapon by multiplying price, weight, and volume by 10.

INDIRECT FIRE CONTROL

Indirect fire control consists of on-carriage sights and off-carriage fire-direction centers.

Indirect fire may be conducted by projectile weapons (CPR guns and electromagnetic mass drivers) and meson guns. While projectile weapons loft their rounds over obstructions to hit their targets, meson guns simply fire through obstructions to hit unseen enemies.

In order to conduct indirect fire, a weapon must have an on-carriage indirect fire sight, which in its simplest form amounts to precise calibration of elevation and traverse enabling the gunner to make exact corrections. More advanced forms allow more precise corrections or access to computerized fire control assistance. This is reflected in the fact that the tech level of the installed fire control equipment is the upper limit on the tech level of fire direction center (FDC) that may be used by that weapon.

Indirect fire sights on mortars have half the weight and cost of those for CPR guns.

Fire direction centers coordinate the fire of several guns at a single target, convert correction requests from forward observers into precise elevation and traverse commands, and calculate the effects of a wide variety of factors on gun accuracy (such as atmospherics, different elevations between the firing guns and the target, and so on). While fire direction centers are not required to conduct indirect fire, they increase the effectiveness of that fire dramatically.

For fire conducted through a fire direction center, the task roll to hit the target is a Difficult (instead of Formidable) task.

Fire direction centers substitute the appropriate weapon skill/asset of the main operator (usually the most skilled gunner in the FDC) for the weapons skills of the gunners of all the weapons controlled by the FDC (called "the battery"). All weapons in the battery must have a communication link to the FDC.

FDCs have a correction delay time (in combat turns) and an effective indirect fire range (in kilometers). The more sophisticated the FDC, the shorter the correction delay and the longer the effective range. Indirect fire at ranges beyond the effective range of the FDC is allowed, but the task roll to hit to hit is Formidable instead of Difficult.

Indirect Fire Sights

TL	*Mass*	*MCr*
4	.05	0.004
5	.05	0.006
6	.075	0.008
7	.1	0.01

16-17	0	100	5
18-20	0	150	8
21+	0	300	10

Weapon Stabilization

As a vehicle moves, the weapons mounted on it move as well, and since the ground over which the vehicle travels is uneven, the movement of the weapons will be almost as uneven (the vehicle's suspension compensates for this somewhat). That makes it almost impossible to aim and fire a weapon while the vehicle is moving.

The answer is stabilization. A stabilized weapon has its power traverse and elevation linked to a gyrostabilizer which automatically adjusts the position of the weapon to match the movement of the vehicle, allowing aimed fire on the move. As stabilization becomes more effective, vehicles are able to aim and fire their weapons at higher speeds. The three types of stabilization are shown in the Stabilization table.

Stabilization gear stabilizes all weapons in a single mount. The Stabilization table expresses the mass of the gear as a percentage of the weight of the weapon being stabilized. The mass of the weapon includes the mass of its fire control/sights, its mechanical loading assistance, and its ammunition if it is a magazine-fed automatic weapon or autocannon. If it has an autoloader, half of the mass of the autoloader is included in the mass of the weapon, but not the ammunition mass. The gear is located on the mount; however, the stabilization gear for an open mount is located in the chassis. The minimum weight is that for 1 tonne of weapon, even if the weapon's weight is much less than a tonne.

Stabilization

TL	*Type*	*Mass*	*MCr*	*Fire if Move*
6	Basic	0.05	0.02	Full safe speed
7	Good	0.075	0.04	Twice safe speed
8+	Advanced	0.1	0.05	Any speed

TL: Tech level of first availability.

Mass: The mass, in tonnes, of the stabilization gear is equal to the mass, in tonnes, of the stabilized weapon times the listed decimal.

MCr: Price, in millions of credits, of the stabilization gear.

Fire if Move: The limit to vehicle movement while firing with that stabilization gear. Safe speed is safe road or safe off-road speed, whichever mode the vehicle is in.

Vol: The volume of the stabilization gear in cubic meters is equal to its mass in tonnes.

Beam Pointers

All heavy (non-small arms) lasers, particle accelerators, and meson guns require beam pointers, which represent the integral fire control capabilities installed on the mount. Beam pointers may only be used on these classes of weapons.

Select a beam pointer from the table on the following page based on the weapon's tech level and the range performance desired. Note that range is given in kilometers and 30,000-km hexes/range bands for space combat. The listed range in km/hexes of the selected beam pointer will be the weapon's short range for purposes of combat.

Special Note on Planetary Combat: Weapons equipped with beam pointers receive the Diff Mod benefits of a ballistic computer of the same tech level (see facing page) when they use direct fire in planetary (ground) combat. This is because these weapons are effectively ballistically perfect and arrive virtually instantaneously at their targets at planetary ranges.

This is for planetary combat *only*; beam pointers allow no Diff Mods to be negated in space combat, only master fire directors (MFDs, see next page) may do this.

Any beam pointer-equipped weapon linked to an MFD which conducts direct fire under MFD control in planetary combat receives the benefits of a point defense computer (see facing page) of the same tech level (beam pointer or MFD, whichever is lower).

When a weapon has its performance adjusted for atmosphere, remember that its atmosphere-adjusted ranges are for purposes of damage calculation only. Its short range (and medium, long, and extreme ranges which are derived from it) based on installed beam pointer are still used for resolving hits.

Range below is given in km and in space combat hexes/range bands.

Beam Pointers

Range	*Volume in m³ at Tech Level*							
(in km/hexes)	*8*	*9*	*10*	*12*	*14*	*15*	*17*	*19*
0.3/0*	0.1	0.05	0.04	0.03	0.02	0.01	0.006	0.004
3/0*	0.2	0.1	0.08	0.06	0.04	0.02	0.01	0.006
30/0*	0.4	0.2	0.15	0.12	0.08	0.04	0.02	0.01
300/0**	0.8	0.4	0.3	0.24	0.15	0.08	0.04	0.02
3000/0†	1.5	0.8	0.6	0.5	0.3	0.15	0.08	0.04
30,000/1	3	1.5	1.2	1	0.6	0.3	0.15	0.08
60,000/2	6	3	2.4	2	1.2	0.6	0.3	0.15
90,000/3	9	4.5	3.7	3	1.8	0.9	0.45	0.25
120,000/4	12	6	5	4	2.4	1.2	0.6	0.3
150,000/5	15	7.5	6	5	3	1.5	0.75	0.4
180,000/6	18	9	7	6	3.6	1.8	0.9	0.45
210,000/7	21	10.5	8	7	4.2	2.1	1.0	0.5
240,000/8	24	12	9	8	4.8	2.4	1.2	0.6
270,000/9	27	13.5	10	9	5.4	2.7	1.3	0.65
300,000/10	30	15	11	10	6	3	1.5	0.75

*Weapon cannot be used in space combat, even in same hex.

**Use extreme range (base difficulty of Impossible) for task difficulty in same hex; task is not possible outside of same hex.

†Use long range (base difficulty of Formidable) for task difficulty in same hex; task is not possible outside of same hex.

Volume: The volume of the beam pointer in cubic meters.

Mass: The mass of the beam pointer, in tonnes, is equal to its volume in cubic meters.

Price: The price, in millions of credits, is equal to the volume in cubic meters multiplied by 0.1.

Master Fire Directors

Spacecraft may be equipped with master fire directors (MFDs) which enhance the performance of installed weapons. While many small ships with only one or two turrets rely on local turret control and do not contain MFDs, warships will want several directors. Each MFD must be provided with a pencil-beam active sensor of its own, with a short range equal to the listed range of the fire director. The values for this sensor must be chosen from the Radar table (for TL 8-9 fire directors) or Active EMS table (for TL 10+) in the Electronics chapter (Section 5), except that the power requirement and antenna size listed are multiplied by 0.1 and the cost is multiplied by 0.5. Volume and mass figures are unchanged. These numbers are added to those of the MFD, as they constitute one piece of equipment. The sensor is not used separately under any circumstances, but is necessary for the normal functioning of the MFD.

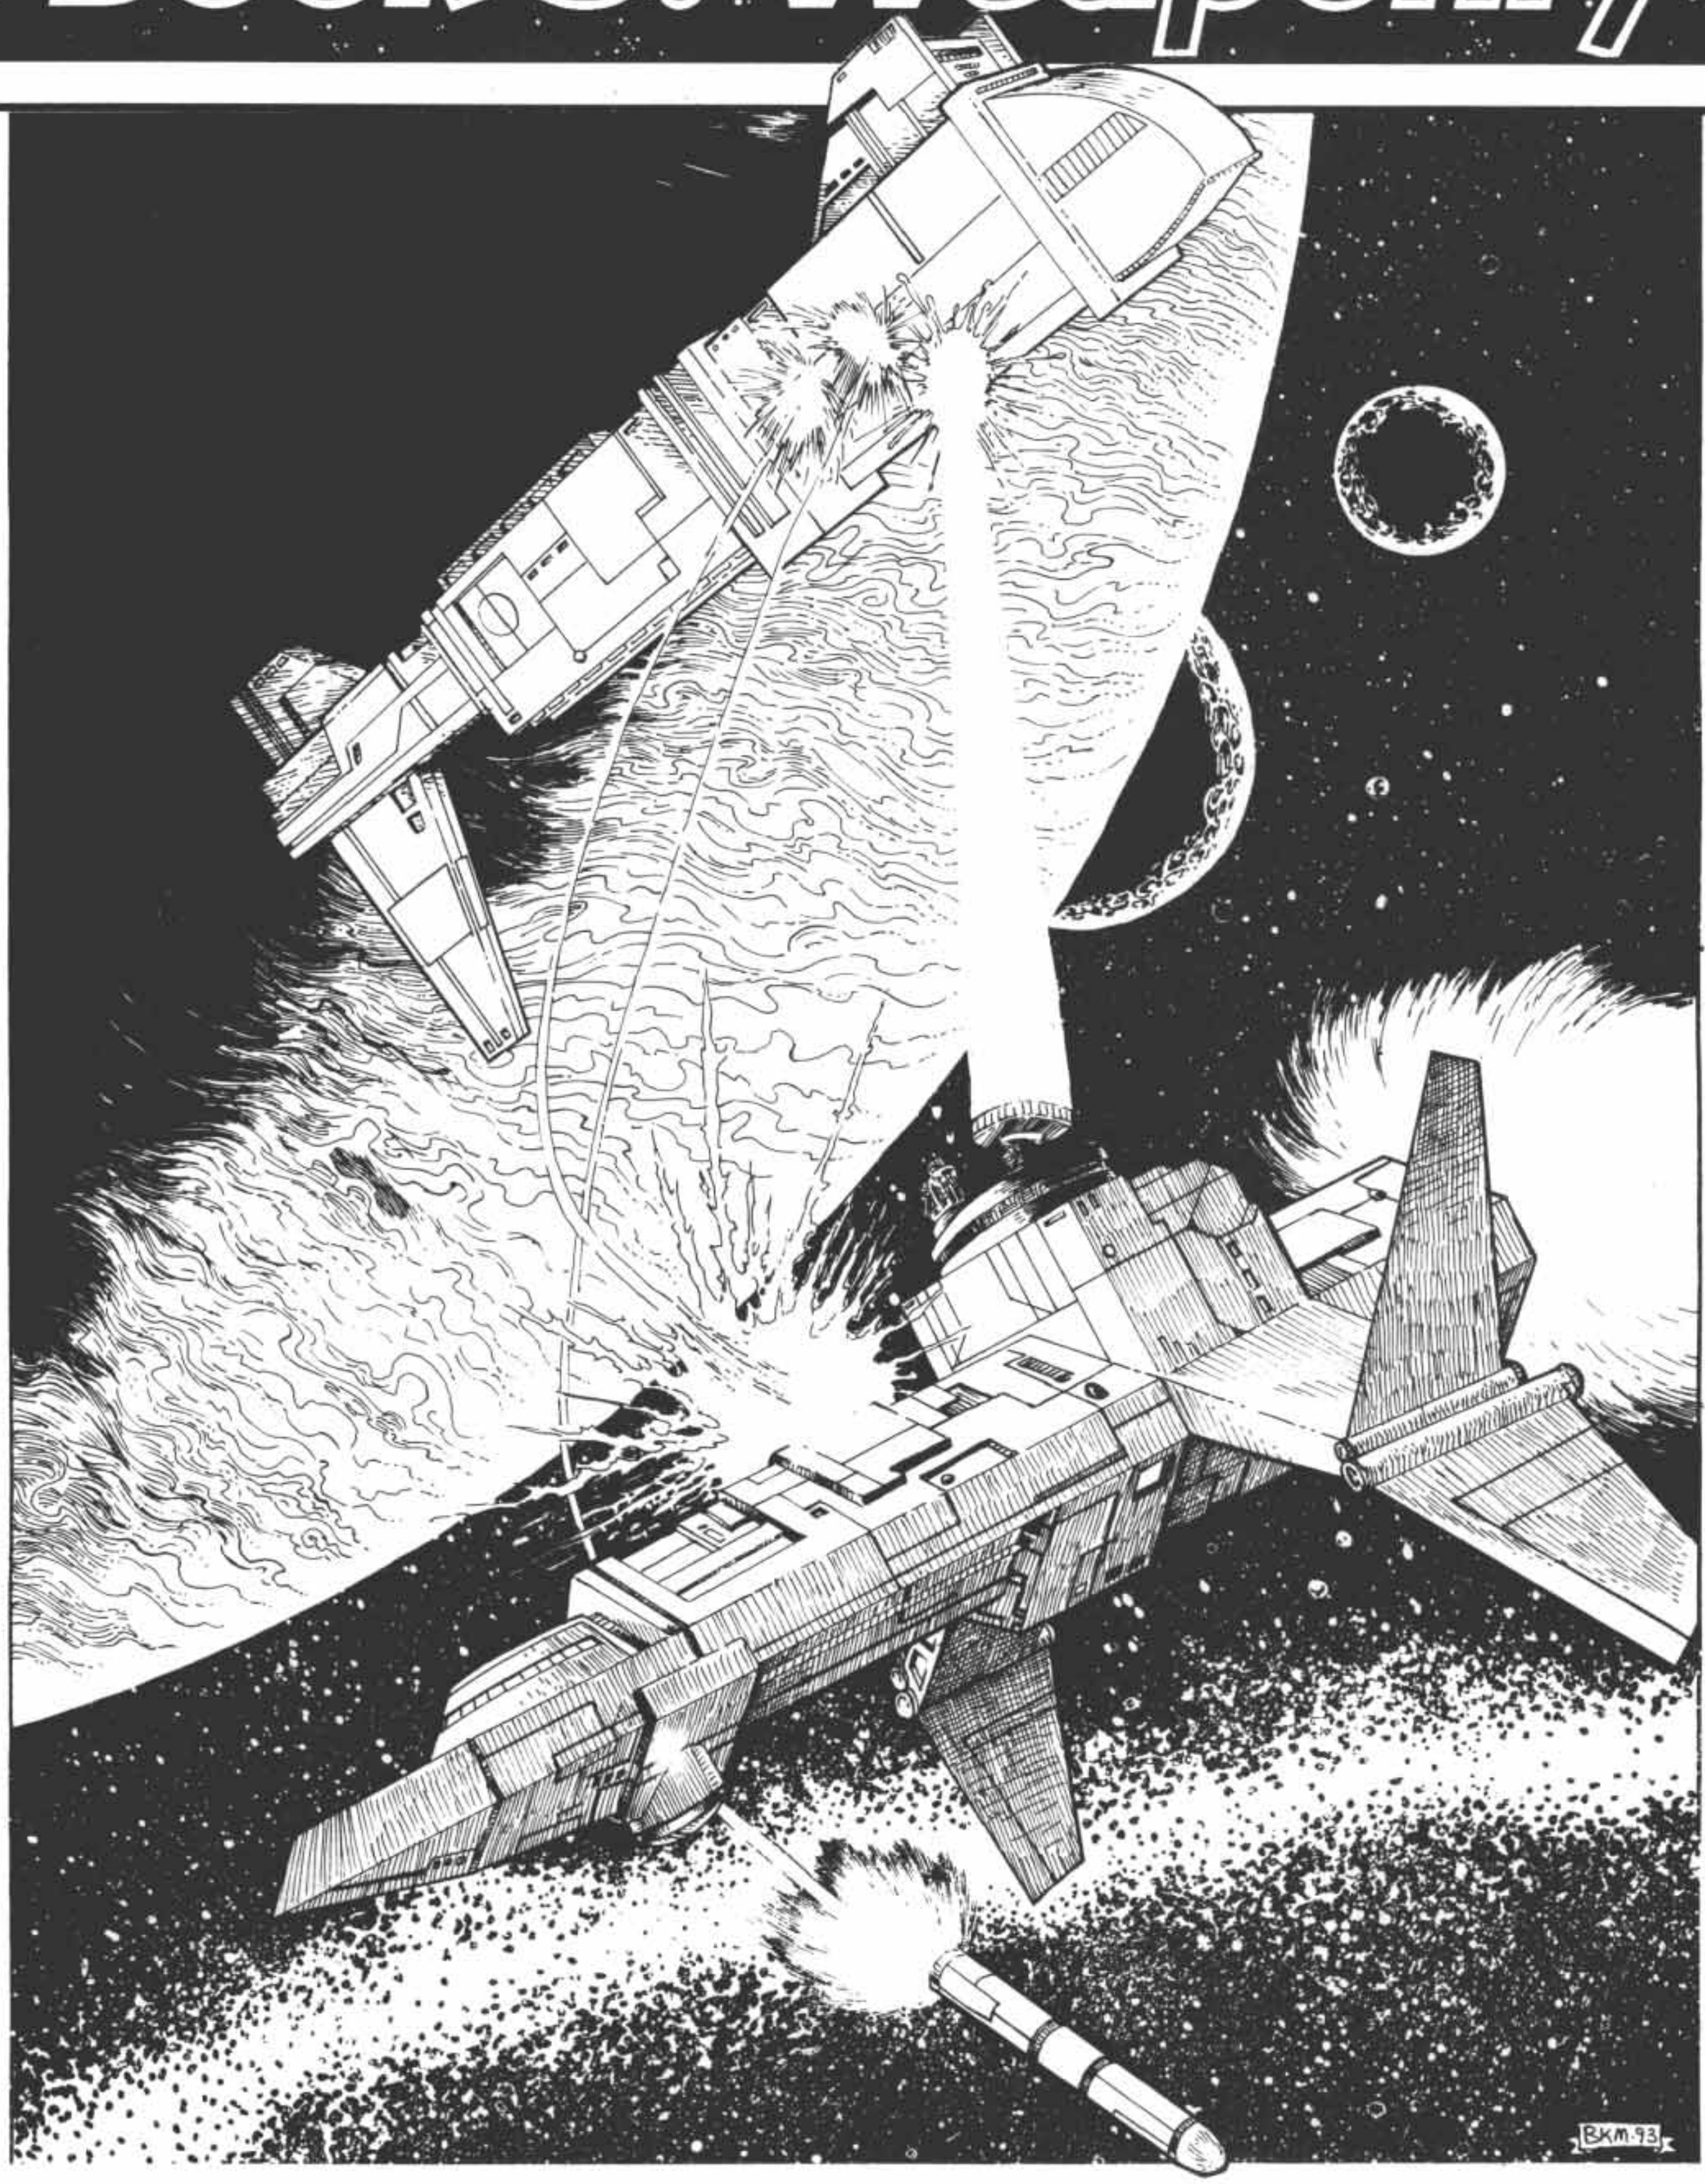
If an MFD is to have the capability to control missiles, it must have a laser or maser communicator from the same tech level installed with it as well. Like the pencil-beam sensor above, it is considered part of the MFD and may not be used for any other purpose, but its full cost, power, and antenna size are used. This communicator should be the same type as installed on the missiles that will be used with the MFD, as the short (automatic contact) range will be limited to that of the MFD or the missile, whichever is shorter. The number of missiles that can be simultaneously controlled by an MFD is equal to the "Diff Mod" listing. When the missile detonates and fires, the missile can only use the MFD's ability to ignore Diff Mods if it is within the MFD's extreme range (8 times the short range shown on the table). Designers should choose the range of their missile control MFDs accordingly.

Note that the task-range performance of weapons that are being fired by an MFD is limited to the range of the MFD if that is shorter than that of the weapon. Therefore, players should take care to install MFDs whose range performance matches that of the installed weapons. A vehicle equipped with an MFD must also be equipped with a St or Fb model computer of equal or higher tech level (see Section 4). MFD crew are not handled at this step. MFD crew are allocated workstations on the bridge or flight deck and are handled in that portion of Major Systems.

Master Fire Directors

Range	*Volume at Tech Level*							
	8	*9*	*10*	*12*	*14*	*15*	*17*	*19*
0.3	0.2	0.1	0.08	0.06	0.04	0.02	0.01	0.006
3	0.4	0.2	0.16	0.12	0.08	0.04	0.02	0.01
30	0.8	0.4	0.3	0.24	0.16	0.08	0.04	0.02
300	1.6	0.8	0.6	0.48	0.3	0.16	0.08	0.04
3000	3	1.6	1.2	1	0.6	0.3	0.15	0.075
30,000/1	6	3	2.4	2	1.2	0.6	0.3	0.15
60,000/2	12	6	4.8	4	2.4	1.2	0.6	0.3
90,000/3	18	9	7.4	6	3.6	1.8	0.9	0.45
120,000/4	24	12	10	8	4.8	2.4	1.2	0.6
150,000/5	30	15	12	10	6	3	1.5	0.75
180,000/6	36	18	14	12	7.2	3.6	1.8	0.9
210,000/7	42	21	16	14	8.4	4.2	2.1	1.05
240,000/8	48	24	18	16	9.6	4.8	2.4	1.2
270,000/9	54	27	20	18	10.8	5.4	2.7	1.3
300,000/10	60	30	22	20	12	6	3	1.5
Diff Mod	1	2	3	4	5	6	7	8

Range: Short range in kilometers/space combat hexes.



Diff Mod: The number of cumulative adverse difficulty modifiers to hit the fire director ignores, also the number of missiles it may control at one time.

Mass: Mass in tonnes equals volume × 1.

MCr: Price in millions of credits equals volume × 1.

MW: Power requirement, in megawatts, equals volume × 0.01.

Book 3: Weaponry

CHAPTER 1
Small Arms Design

This design sequence is aimed at designing "modern" firearms, by which we mean firearms using a fixed cartridge consisting of a bullet (or bullets), propellant, and primer. The ability to manufacture this type of ammunition appears at middle tech level 3, with the near-simultaneous development of advanced metal-working technology (for cartridge cases) and more stable and reliable primers, and becomes widely available at tech level 4.

As classic firearms are defined almost as much by their ammunition as by their own construction, small arms design consists of two parts: ammunition design and weapon design.

PART 1: AMMUNITION DESIGN

Ammunition is defined by four characteristics: the tech level, the diameter of the bullet in millimeters (also referred to as caliber), the length of the cartridge case in millimeters, and the type of cartridge case (straight, necked, or shotgun). In some cases, the type of cartridge case is further defined as ETC (Electrothermal Chemical) indicating that it is fired from a specially designed ETC gun with an electric pulse which both enhances the power of the propellant and smooths out its energy curve to increase its efficiency. Ammunition for gauss weapons is handled in the gauss weapon design sequence.

Tech Level: Modern ammunition (propellant and bullet carried in a metallic cartridge case and fired by means of a primer in the base of the cartridge case) becomes available at mid tech level 3 and becomes universally used at tech level 4. Electrothermal-chemical (ETC, see page 137) cartridges are widely available at tech level 9, and all non-ETC cartridges are by then caseless. By tech level 12, conventional small arms have mostly been supplanted by gauss and directed energy weapons.

Bullet: The diameter of the bullet in millimeters is called its caliber, and weapons are commonly referred to by their caliber, such as 9mm. Although standard weapons listed in the game are usually in increments of 0.5 millimeters (such as 5.5mm, 7.5mm, etc.), weapons may be designed in any caliber desired, such as 11.43mm or 4.71mm. Small arms may be made in any caliber up 20mm. (Weapons of 20mm and above are usually considered to be cannons.)

If the round is to be a shotgun shell, it should be specified at this point, as should the number of bullets in the shell. The number of bullets in the round must either be one (a single large slug) or any multiple of four.

Cartridge Case Length: The longer the cartridge case, the more propellant contained in it and the more powerful the ammunition. Ammunition is often referred to by two numbers, the caliber followed by the cartridge case length, which helps distinguish it from other ammunition of the came caliber. Sometimes the ammunition will also have a common name under which it is sold to the public. For example, 7.62×25mm pistol ammunition is today commonly called 7.62 Tokarev, since it is usually fired from a Tokarev pistol, while 7.62×51mm rifle ammunition is commonly called 7.62 NATO, since it is the standard large-caliber NATO rifle cartridge. In the case of shotgun shells, the length includes the container for the bullets as well, and so 12-gauge shotgun shells (the most common current shotgun round) is also called 18.5×70mm round.

Cartridge Case Type: For our purposes there are three general types of cartridges: straight, necked, and shotgun.

Straight cartridges have a cartridge case approximately the same diameter as the bullet along its entire length, while necked cartridge cases are larger in diameter than the bullet and then "neck down" at the end to fit the bullet. Necked cartridge cases are considerably more powerful than straight cases and are usually fired from rifles, while straight cartridges are usually fired from pistols and submachineguns. Necked cartridges carry a longer, heavier bullet than do straight cartridges, and the cartridge case must be at least 35mm long in order to be necked. (There do exist some short pistol rounds that are slightly necked, but these are included under straight rounds because their performance is not sufficiently different from straight rounds to justify a distinction.) Shotgun cases are straight cases with fairly light powder charges and either multiple small bullets or a single large slug.

Necked cartridges are not available until tech level 4. Because all non-ETC cartridges at TL 9+ are caseless, it is the cartridge dimensions which are specified here, and not the case.

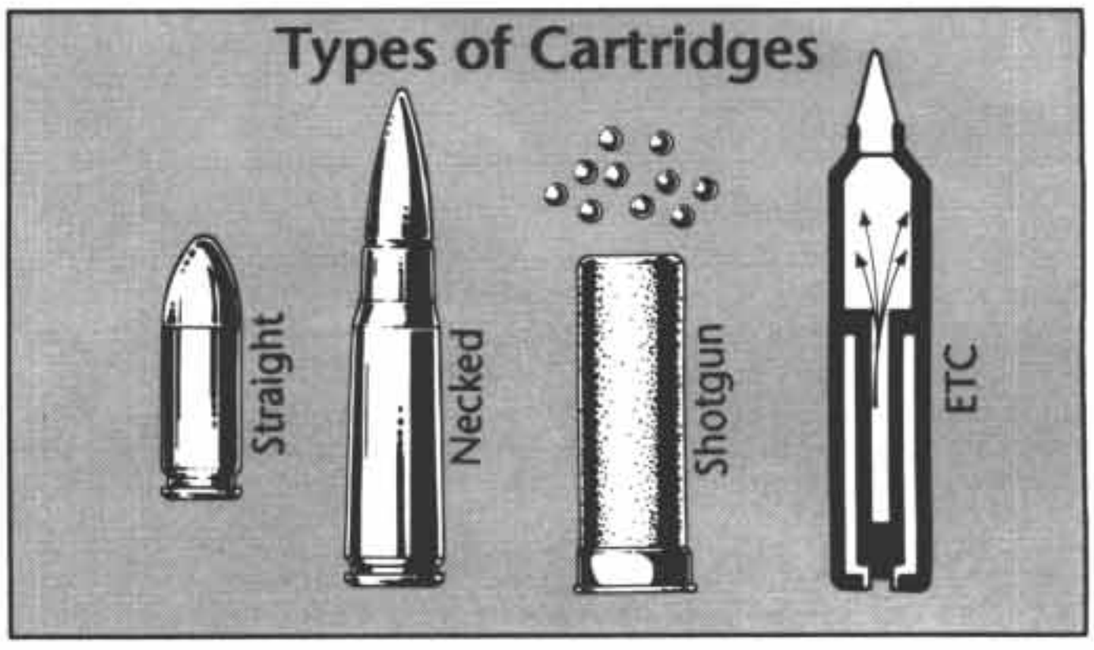
Note: In the sequences below, unless otherwise instructed, round all results to the nearest whole number.

Ammunition Evaluation

Once the ammunition round has been designed, determine its length, weight, magazine weight, and average muzzle energy.

Length: The ammunition length is determined using the following formulae:

Lasg = Lcc
Las = Lcc + d
Lan = Lcc + 2d



Lasg: Length (in millimeters) of shotgun ammunition.

Las: Length (in millimeters) of ammunition with a straight cartridge case.

Lan: Length (in millimeters) of ammunition with a necked cartridge case.

Lcc: Length (in millimeters) of the cartridge case.

d: Diameter (in millimeters) of the bullet.

Weight: The ammunition weight is determined using the following formula:

$$Wa = AwcLcc\ \pi\ r^2$$

r: Radius (in millimeters) of the bullet (half the diameter).
π: 3.1416
Wa: Weight (in grams) of a complete round of ammunition.
Lcc: Length (in millimeters) of the cartridge case.
Awm: Ammunition weight multiplier, which depends on whether the ammunition is a conventional round or a shotgun shell, as shown below.

Ammo Type	*Awm*
Shotgun shell	0.003
Straight	0.008
Necked	0.01

Average Muzzle Energy: The average muzzle energy of conventional and ETC ammunition is determined using the following formula. (The actual muzzle energy will be affected by the design of the weapon itself.)

$$Ea = TmCmLcc\ \pi\ r^2$$

Ea: Average muzzle energy (in joules) of a cartridge.
Lcc: Length (in millimeters) of the cartridge case.
r: Radius (in millimeters) of the bullet (half the diameter).
π: 3.1416
Tm: Tech level modifier, as shown on the table below

TL	*Tm*
3	0.6
4	0.7
5	0.8
6	0.9
7	1
8	1.1
9+	1.3

Cm: Cartridge modifier, as shown on the following table:

Cartridge Type	*Cm*
Shotgun	0.2
Shotgun ETC	0.3
Straight	0.4
Straight ETC	0.8
Necked	1.6
Necked ETC	3.2

Price: The price of the ammunition is determined by the following formula:

$$Cr = WTm$$

Cr: Price in credits
W: Weight of the round in grams.
Tm: Type multiplier, as determined below:

Type	*Tm*
Shotgun	0.01
Mass-produced military ammo	0.02
Conventional	0.04
High-powered (Ea = 10,000+)	0.05

Special Ammunition

The above design sequence deals with solid slug ammunition (usually called "ball" ammunition). A variety of special small arms ammunition is available as well.

HE: HE, or high-explosive, ammunition (also variously called shredder or exploder) is hollow and contains an explosive filler that detonates on impact.

HE rounds are not available before TL 6. Price for HE rounds is multiplied by 2.

DS: DS, or discarding sabot, ammunition (also called SLAP, for saboted, light armor-piercing) is a high-velocity bullet designed to penetrate armor.

DS small arms rounds are not available before tech level 8. Price for DS rounds is multiplied by 2.

HEAP: HEAP, or high-explosive armor-piercing, bullets are hollow, as with HE bullets, but have small shaped charges for penetrating armor.

HEAP small arms rounds are not available before tech level 9. Price for HEAP rounds is multiplied by 3.

Tranq: Tranq rounds are nonlethal means of subduing adversaries.

Tranq small arms rounds are not available before tech level 6. Price for Tranq rounds is multiplied by 2.

PART II: WEAPON DESIGN

1. Barrel

The barrel of a firearm carries the bullet after the cartridge is fired. The barrel is usually rifled, and so imparts a spin on the bullet, giving it stability (and thus accuracy) in flight. (Shotguns, intended for very short ranges, fire their bullets through a smooth bore.) In addition, the barrel provides a gas-tight constricted space within which the expanding gas of the exploded propellant can act on the bullet, accelerating it. Once the bullet leaves the muzzle of the barrel, however, it begins decelerating. In general, the longer the barrel the higher the muzzle velocity, up to the point where the bullet reaches its greatest possible velocity.

Average Barrel Length: First, determine the average barrel length for the ammunition being used by the weapon. The following formula is used:

$$Bla = (Ea \div d^2)Rm$$

Bla: Average barrel length (in centimeters)—the length of the barrel which allows the ammunition to achieve its average muzzle energy.
Ea: Average muzzle energy (in joules) of the ammunition.
d: Diameter (in millimeters) of the bullet.
Rm: Rifling multiplier, as shown below:

Type	*Rm*
Smoothbore	4
Smoothbore ETC	3
Rifled	1
Rifled ETC	0.5

Note: Regardless of the results of the above calculations, average barrel length is never less than 10cm.

Actual Barrel Length: The actual barrel length can be any length desired down to a minimum of 20% of the average barrel length and
1 up to a maximum of 230% of the average barrel length.

Type of Barrel: Two types of barrels are possible: heavy barrels and light barrels. Heavy barrels are required for machineguns or other weapons intended to be used at a high sustained rate of fire, any
2 weapon intended to mount a bipod, and any weapon with firing a cartridge with an average muzzle energy greater than 5000 joules. Light barrels may be used for all other weapons, including shotguns.

Barrel Weight: The weight of the barrel is determined using the
3 following formulae.

Wbl = .02Lb

Wbh = .03Lb

Wbl: Weight (in kilograms) of a light barrel.

Wbh: Weight (in kilograms) of a heavy barrel.
4 *Lb:* Length (in centimeters) of the barrel.

Barrel Price: The price of the barrel is determined using the following formula:

Cr = WbBtm
5

Cr: Price of the barrel in credits.

Wb: Weight of the barrel in kilograms

Btm: Barrel type multiplier, as determined by the following table:

6

Type	*Btm*
Smoothbore	100
Light rifled	200
Heavy rifled	400

7 **Actual Muzzle Energy:** Once the barrel length is decided on, the weapon's actual muzzle energy can be determined using the following formula.

E = Ea{1 + (0.5[Blp–1])}
8

E: Actual muzzle energy (in joules) of the weapon

Ea: Average muzzle energy (in joules) of the ammunition

Blp: Actual barrel length (cm) divided by Average barrel length (cm): Bl÷Bla.
9

Bl: Actual length (in centimeters) of the barrel of the weapon.

Bla: Average barrel length (in centimeters) for the ammunition used.

If a multiple-bullet round is fired from the weapon, divide the
10 actual muzzle energy of the round by the number of bullets in the round to determine the energy of each bullet.

If the round fired is Tranq, multiply the muzzle energy by 0.6.

Damage: Once muzzle energy is known, it is possible to calculate
11 damage and using the following formula.

D = (√E)÷15

D: Damage value (if D = less than 0.8, damage is 1D6–1)

E: Muzzle energy (in joules)

12 With a multiple bullet round damage is calculated separately for each bullet. The result is the medium range damage of each bullet. The short range damage *of the entire round* is determined by the following formula:

Dr = .75NDb
13

Dr: Damage value of the round.

Db: Damage value of a single bullet.

N: Number of bullets in the round.

Note that damage for shotgun shells loaded with a single slug is
14 calculated in the same way as any other single bullet round.

HE and HEAP bullets cause additional damage from the explosion of the round. The explosive energy is determined by adding the diameter of the bullet (in millimeters) to the tech level of the bullet and subtracting 7, then cubing the resulting number. The result is the explosive energy of the bullet. When calculating damage, the value for E in the formula becomes the sum of muzzle energy and explosive energy.

All Tranq rounds have a damage value of –1* (1D6–1 damage points) where the "*" refers to their tranq effects as determined by the rules for Tranq rounds found on page 350 of the basic **Traveller** rules.

Penetration: It is also possible to determine penetration once muzzle energy is known by consulting the following table.

E	*Pen*
0-600	Nil
601-2000	1-Nil
2001-3000	2-Nil
3001-5000	2-3-Nil
5001-10,000	2-4-6
10,001-20,000	2-3-4
20,001-50,000	2-2-3
50,001+	2-2-2

Shotguns are an exceptions to this, as their bullets tend to be heavier but slower-moving. All shotgun bullets (both slugs and multiple-projectile bullets) have a penetration of 3-4-5.

(Note that the very high short-range damage of multiple-bullet shotgun shells is caused by multiple-bullet hits, each with a lower damage value. In most cases the penetration of multiple bullets from a shotgun will be Nil, but see the more complete explanation of penetration notation later for possible special cases.)

For DS ammunition, subtract 1 from each penetration number of the penetration value of the weapon. For example, a penetration of 2-4-6 would become 1-3-5. If one of the values is already 1, it remains 1. If one of the values is Nil, it becomes 1 higher than the previous value and Nil is added after it. For example, a penetration of 1-Nil would become 1-2-Nil. Ammunition with a listed penetration of Nil becomes 1-Nil instead.

Fore HEAP ammunition, penetration is always 2-2-2.

For HE and Tranq ammunition, penetration is always Nil.

For multiple bullet rounds, calculate the penetration of each bullet separately. If this results in a penetration other than nil (which will be extremely rare), it will be necessary to recalculate the damage of each bullet at short range, as each bullet loses energy passing through armor. Assume that the target is hit by 75% (rounding fractions to the nearest whole number) of the bullets contained in the round.

2. Receiver

The receiver is the mechanical heart of a firearm. It "receives" the cartridge from the magazine, places it in the chamber, holds it in place with the bolt, and fires it with the firing pin. Some receivers, such as in bolt-action rifles, are manually operated, while others, such as in automatic and semiautomatic weapons, are operated by gas from the fired round or direct recoil energy.

Weapons which fire ammunition with high muzzle energy require heavier and longer receivers, as do weapons intended for high sustained rates of fire. Sometimes weapons are given heavier receivers simply to absorb additional recoil, and thus allow more accurate fire.

Receiver Type: There are a number of different types of receivers which define the method of operation of the weapon. All receivers are divided into two general categories: heavy and light.

In the case of self-loading receivers (automatic and semiautomatic weapons), both light and heavy receivers are available. Weapons intended to operate primarily or exclusively on the automatic setting (machineguns) should have a heavy receiver. All belt-fed or cassette-

fed weapons must have a heavy receiver. Weapons intended to operate only in semiautomatic fire, or which are selective fire weapons, may use a light receiver (but are not required to).

At tech level 9 and above, any receiver may be constructed as an ETC receiver by so designating in the design process.

TL	*Action*	*Weight*
3	Individually loading	Light
3	Revolver	Light
3	Lever-action	Heavy
4	Bolt-action	Light
4	Pump-action	Light
4	Heavy self-loading	Heavy
5	Light self-loading	Light

Rate of Fire: Individually loading, lever-action, bolt-action, and pump-action weapons have rate of fire (ROF) codes of SS (single shot), LA (lever action), BA (bolt action), and PA (pump action) respectively.

Revolvers from tech level 3 have an ROF code of SAR (single-action revolver) while those from tech level 4 or higher have a code of DAR (double-action revolver).

Weapons with light self-loading receivers may be either semiautomatic (ROF code of SA) or selective fire, with a full automatic rate of fire of either 3 or 5 shots per burst, at the designer's option (selective fire always includes the single-shot SA option).

Heavy self-loading receivers may be either semiautomatic (ROF code of SA) or selective fire (ROF code of either 3, 5, or 10).

With selective fire, the designer must specify how many rates of fire are available (single-shot SA is always available in all self-loading receivers). That is, a selective fire weapon may have a listed ROF of 5/10, meaning that it can be fired as a semiautomatic weapon, an automatic weapon with an ROF of 5, or an automatic weapon with an ROF of 10.

Receiver Length: Receiver length is determined by the following formula:

$$Lr = Tm(\sqrt{Ea})$$

Lr = Length (in centimeters) of the receiver
Tm = Tech level multiplier, as shown below
Ea = Average muzzle energy (in joules) of the ammunition

TL	*Tm*
4-5	.55
6-7	.5
8-9	.45
10+	.4

Receiver length must always be at least as long as the cartridges it fires.

Receiver Weight: Once the type of receiver is known, its weight can be calculated using the following formulae:

$$Wrl = .001Ea$$
$$WrlET = .0005Ea + 0.3$$
$$Wrh = .002Ea$$
$$WrhET = .001Ea + 0.3$$

Wrl: Weight (in kilograms) of a light receiver.
WrlET: Weight (in kilograms) of a light receiver of an ETC gun.
Wrh: Weight (in kilograms) of a heavy receiver
WrhET: Weight (in kilograms) of a heavy receiver of an ETC gun
Ea: Average muzzle energy (in joules) of the ammunition.
For shotguns, multiply receiver weight by 0.6.

Receiver Price: The price of the receiver is based on its weight and type of action, according to the following formula:

$$Cr = WrAm$$
$$CrET = WrAm+200$$

Cr: Price in credits
CrEt: Price in credits of ETC receiver
Wr: Weight (in kilograms) of the receiver
Am: Action multiplier, as shown below

Action	*Am*
Individually loading	50
Revolver	150
Lever-action	300
Bolt-action	300
Pump-action	300
Self-loading SA	200
Self-loading selective	250
Self-loading deluxe	300

Notes: A self-loading selective receiver is a selective fire receiver with semiautomatic fire and one automatic ROF. A self-loading deluxe receiver is a selective fire receiver with, in addition to semiautomatic fire, more than one automatic rate of fire option (regardless of how many).

Doubles

Any weapon using an individually loading receiver may have more than one barrel if the designer wishes (this is common in shotguns and large-bore rifles). Each barrel must have its own individually loading receiver, but only one stock/grip is needed. These barrels need not be identical in caliber, but they must be identical in length.

It remains for the designers and users of such weapons to discover the practical limit on the number of barrels to be incorporated into such a design, but such weapons normally only include two (hence the name), and seldom more than three. Double-barreled shotguns are the most common, but it is not uncommon to combine a smoothbore shotgun barrel with a rifle barrel, or two rifle barrels. Double weapons are primarily used for hunting, and are seldom used for military purposes due to their obvious drawbacks (low magazine capacity, lengthy reloading time, and relatively heavy weight).

3. Stocks

Stocks refer to rifle stocks and pistol grips. The desired stock for the weapon is selected from the following table. Note that carbine stocks are generally fitted to rifles with short barrels (up to 80% of the average barrel length for the cartridge) or sport versions of rifles. They are not considered sturdy enough for full-length rifles in military use. If a weapon (such as a machinegun) is to be used exclusively from a tripod or a vehicle, it only needs a pistol grip instead of a stock.

TL	*Type*	*L (cm)*	*M (kg)*	*Cr*
4	Wood pistol grip	0	0.2	5
5	Hollow pistol grip	0	0.1	25
4	Wooden stock	25	1	25
4	Carbine stock	25	0.7	20
6	Folding stock	5/25	0.5	50
7	Plastic stock	25	0.5	30
7	Bullpup	5	0.1	10

Range: Once the type of stock is known, the weapon's range can be calculated according to the following formula:

SR = (√E) CmBlm

SR: Short range (in meters) of a weapon.

E: Muzzle energy (in joules)

Cm: Configuration modifier, as shown below. If two configuration descriptions apply to the same weapon, multiply them together to determine the total configuration multiplier.

Configuration	*Cm*
Bullpup	0.9
Bolt-action	1.1
One-handed	0.4
Two-handed*	1.3
Smoothbore**	0.5

*Two-handed refers to weapons specifically designed to be fired with two hands, and thus including a stock instead of simply a pistol grip. However, all vehicle- or tripod-mounted weapons are considered to be two-handed, even if equipped with only a pistol grip.

**Includes all shotguns.

Blm: Modification to short range for barrel length. The barrel length modifier is determined by the following formula:

Blm = 1 + ([Blp–1]×C)

Blm = Barrel Length Modifier

Blp = Actual barrel length (cm) divided by Average barrel length (cm): Bl÷Bla

Bl = Barrel Length

Bla = Average Barrel Length (for the cartridge)

C = Constant. If Blp–1 is a negative number, the constant is 1.2. If Blp–1 is a positive number, the constant is 0.75.

DS Ammunition: Multiply range by 1.2 for DS ammunition.

HE and HEAP Ammunition: Multiply range by 0.75.

Tranq Ammunition: Multiply range by 0.6, but short range is never more than 30 or less than 4 meters regardless of the calculated value.

Limits on Short Range: Regardless of any modifications made in this step or later (through additions of sights or mounts), the upper limit on the short range of small arms is 300 meters. Even direct line-of-sight energy weapons (such as lasers) are constrained by the physiological limitations of the operator.

4. Feed System

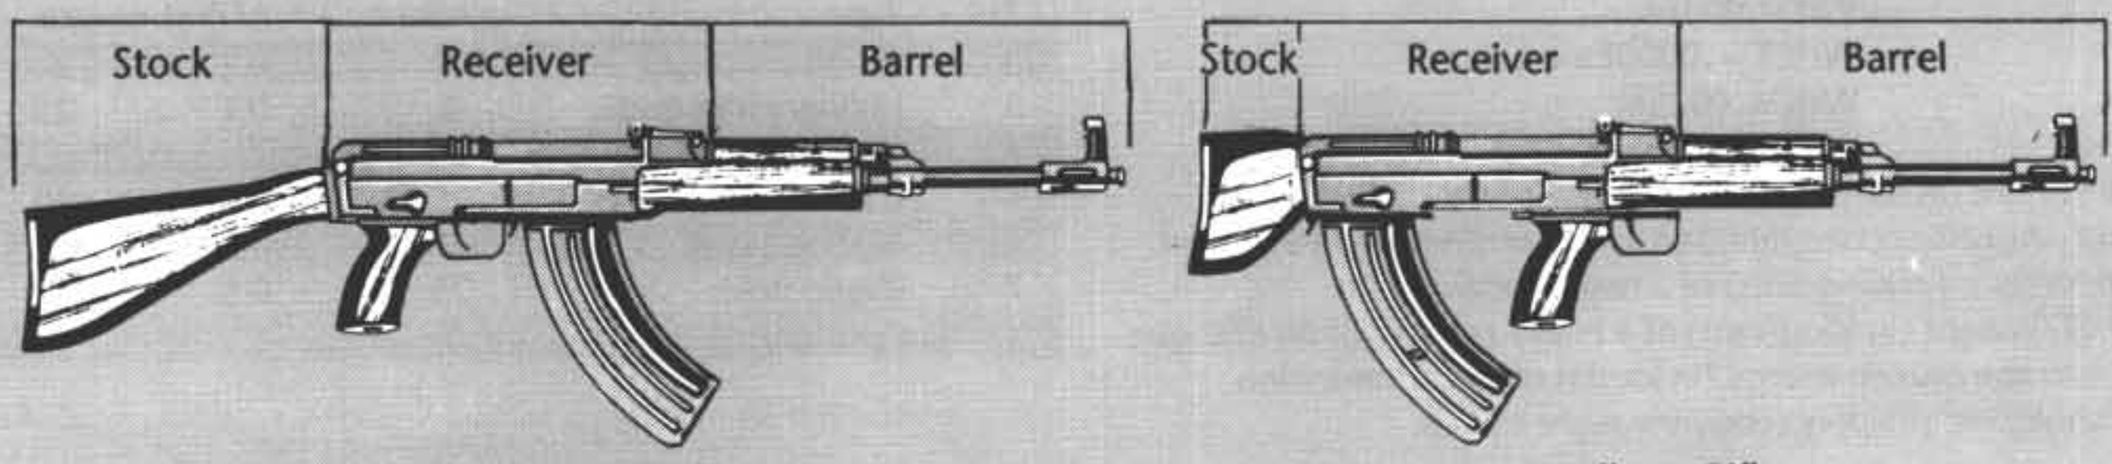
The feed system is the method by which individual rounds are stored in the weapon fed to the receiver.

Breach-Loaded: Breach-loaded weapons have no magazine, as the individual bullets are loaded directly into the receiver.

Cylinder: A cylinder is the magazine of a revolver, but its weight is included in the weight of the receiver. The capacity of the cylinder is 19 divided by the square root of the bullet diameter.

Belt: Belts are linked rounds fed directly into the receiver. Only heavy self-loading receivers may be belt-fed. Belts usually hold 100 rounds, although they may hold more or less if desired. The weight and price of the links are negligible.

Cassette: A cassette is a pre-packaged container of ammunition attached to an endless link feed system which moves the ammunition to the weapon. Only heavy self-loading receivers may be cassette-fed. Cassette feed systems are usually electrically powered, either by batteries or by an engine. Cassette feed systems are available at tech level 7 and above.



A cassette feed system masses 2 kilograms plus the mass of the

Bullpup Configuration

The basic configuration for small arms weapons is a barrel, receiver, and stock. The receiver has to be in the middle, for obvious reasons, and has to be long enough to accommodate the trigger mechanism (usually in the form of a pistol grip) and the feed system (usually a box magazine). The trigger mechanism must be far enough forward from the base of the stock for the firer to comfortably hold it to steady the weapon while aiming. Given these requirements, there doesn't seem to be much room for rifle designers to improve on the classic arrangement of the parts. That being the case, the only way to get a shorter rifle is to shorten the barrel, which adversely affects muzzle energy and range.

The bullpup configuration is a way to partially circumvent the problem. The barrel and receiver are just as long as with a conventional rifle, but the trigger mechanism and feed assembly are placed at opposite ends of the receiver. This allows most of the receiver length to be used for the stock, with only a small recoil pad added to the end. Without sacrificing any critical component, the overall weapon length is reduced.

There are two drawbacks to the bullpup configuration. First, it is more difficult to build the receiver, and make it jam-proof, in this configuration than in the more common one. By tech level 8, however, these engineering problems have been overcome. Second, the sight radius is shorter than on a conventional rifle of the same barrel length, and this reduces accuracy slightly when using iron sights. (This is why there is a configuration modifier to range of 0.9 for a bullpup rifle.) This can be overcome by mounting optical sights, which do not depend upon a long sight radius for accuracy, on the weapon.

Conventional Rifle

Bullpup Rifle

ammunition contained in it. Due to the basic overhead cost of the power and feed system, cassettes seldom hold fewer than 1000 rounds. The price of an empty cassette is equal to the price of a single round of ammunition for the weapon multiplied by 500.

Grip Magazine: Grip magazines are small box magazines inserted through a hollow pistol grip.

Grip magazines may not hold necked cartridges.

The maximum length of bullets in grip magazines, as well as the number of rounds which can be carried in a grip magazine, varies with tech level, as shown in the table below. The capacity, however, applies only to magazines which fit completely inside the pistol grip. Weapons which are never holstered (such as submachineguns) may have longer magazines. The maximum ammo length still applies, but the capacity of the magazine otherwise is determined as for a box magazine.

TL	*Max Al*	*Cap*
4	30	80+d
6	40	100+d
7	50	120+d
8+	60	140+d

TL = Tech level
Max Al = Maximum ammunition length
Cap = Maximum number of rounds in the magazine
d = Bullet diameter

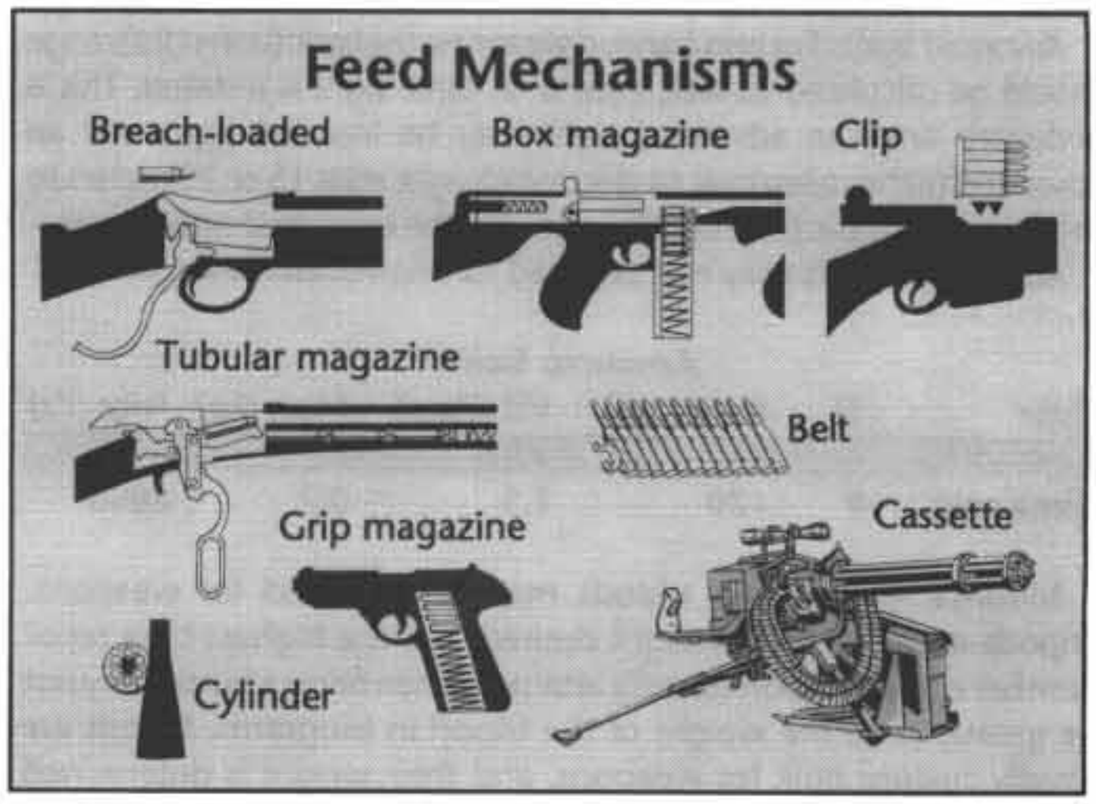
Box Magazine: A box magazine is a spring-loaded metallic or plastic box which is attached to the receiver. A weapon may only be fed by a box magazine if its receiver is at least 150mm longer than the length of the cartridge fired by the weapon.

Clip: A clip is a thin piece of metal holding a group of rounds together. The clip is pushed into the receiver, and the rounds enter a nonremovable internal magazine. The clip is either discarded at that point or ejected by the weapon when the last of the rounds are expended. A weapon may only be clip-fed if its receiver is at least 150mm longer than the length of the cartridge fired by the weapon. The clip itself has negligible mass and price. Clips may not hold more than 10 cartridges.

Tubular Magazine: A tubular magazine is a hollow, spring-loaded metallic tube into which individual rounds are loaded. Tubular magazines are long, must be mounted parallel to the barrel, and so can only be mounted under the barrel, over the barrel, or in the stock.

The maximum capacity (number of rounds) in a tubular magazine is its length divided by the length of a single cartridge, rounding fractions down. The maximum length of the magazine is the barrel length or, if mounted in the stock, 25cm.

Magazine Weight: The weight of an empty magazine (grip magazine, box magazine, clip-fed internal magazine, or tubular magazine) is determined by the following formula.



Wm = .0006(N+4)Wa

Wm: Weight (in kilograms) of an empty magazine.
Wa: Weight (in grams) of a complete round of ammunition.
N: Number of rounds the magazine is designed to hold.

A loaded magazine weighs this plus the weight of the individual rounds loaded into it. Note that in the case of tubular and clip-fed internal magazines, the empty magazine is a permanent part of the weapon and so forms part of its empty weight.

Empty magazines cost Cr10 per kilogram, rounding fractions up.

Electrothermal Chemical Feed Systems: ETC weapons may only be fed by box magazine, grip magazine, belt, or cassette. In all cases, the power source (a fast-discharge battery) is included in the feed device. Belts usually come in ammunition boxes which also contain the battery pack necessary to fire the belt of ammunition. The table below shows the price and weight addition to the feed device *per round* at each tech level.

TL	*Kg*	*Cr*
9	.027	5
10	.019	5
11	.013	5
12	.011	5

In addition, the internal volume available for ammunition is reduced in a grip magazine. When calculating the number of cartridges which can fit in the magazine, add 1 to the effective diameter of the bullets.

Note: The battery packs in ETC magazines are rechargeable and reusable.

5. Options

Sights: The basic ranges calculated above assume traditional iron sights. Optic sights may be fitted instead of iron sights. Optic sights are rugged military versions of telescopic sights, which do not provide the same long-range benefits of those sights but which do improve accuracy. Optic sights increase the weapon's short range as noted below.

Optic Sights

TL	*Range (Mult)*	*Mass (kg)*	*Price (Cr)*
7	×1.05	0.1	150
8	×1.1	0.1	150
9+	×1.15	0.1	150

Laser Sights: A laser sight may be substituted for or added to any other sight. A laser sight allows up to three shots fired during a turn to count as aimed shots (instead of only the first one). All other shots fired during the turn count as quick shots. The sight may only be used at ranges up to its maximum listed range.

Laser Sights

TL	*Mass (kg)*	*Range (m)*	*Price (Cr)*
8	1	40	400
9	1	240	1000
10	0.5	240	300

Advanced Sights: For two-handed weapons, the basic (iron sight) range should be calculated as well, even if an optic sight is installed. This is necessary since an advanced sight may be installed later, and an advanced (either telescopic or electronic) sight adds 15 or 20 meters to the weapon's basic (iron sight) range, not the enhanced optic range.

Advanced sights may not be fitted to one-handed weapons.

Advanced Sights

Type	*TL*	*Range (m)*	*Vol (liters)*	*Mass (kg)*	*Price (Cr)*
Telescopic	6	+15	0.8	0.1	200
Electronic	9	+20	1.5	0.2	2000

Mounts: Bipods and tripods may be provided for weapons. Tripods may be of any weight desired, but the highest base recoil number of the weapon (usually attained when firing a burst) may not be greater than the weight of the tripod in kilograms. Bipods are usually custom built for weapons, and their weight is determined using the following formula.

Wbp = .0005E (but never less than 1 kg)

Wbp: Weight (in kilograms) of the bipod

E: Muzzle energy (in joules)

Recoil: The recoil of a weapon (calculated below after final mass is established) when fired from a bipod is the standard value times 0.5. The recoil of a weapon when fired from a tripod is the standard value times 0.25. Weapons fired from moving vehicle mounts have negligible recoil.

The price of tripods is determined by the following formula:

Cr = 100 + (10W)

Cr: Price in credits.

W: Weight in kilograms.

The price of bipods is determined by the following formula:

Cr = 50 + (10W)

Cr: Price in credits.

W: Weight in kilograms.

Range: Bipods and tripods extend the range of the weapon, as shown on the following table (all vehicle-mounted weapons also receive the tripod modifier).

Mount	*Range*
Bipod	×1.3
Tripod	×2.0

Bayonet Lugs: Bayonet lugs are simple standardized brackets at the end of the weapon barrel. A bayonet lug costs nothing and has negligible mass, but must be specified as part of the design.

A bayonet is less useful than a hand-held knife unless it is mounted on a well-balanced weapon with sufficient length to allow it to be used as a spear point. As a result, only weapons with a bulk (see below) of 4 or more may profitably benefit from a bayonet lug. Shorter weapons may have them, but the mounted bayonet counts as a short range (instead of long range) melee weapon and suffers a +1 Diff Mod for its chance to hit in armed melee combat.

Grenade Adapter: A grenade adapter allows the firing of rifle grenades and adds 5 cm to the length of the weapon and costs Cr50.

Recoil Reduction: There are three types of devices used to reduce recoil: muzzle brakes, shock absorbers, and compensators. No more than one of each type may be added to the weapon. Some weapons enjoy lower recoil because of the type of action employed, and these are treated as a separate fourth type of recoil reduction.

Muzzle Brakes

TL	*Type*	*L*	*W*	*Rcm*	*Cr*
6	Muzzle Brake	4	.2	.9	50
7	Muzzle Brake	4	.2	.85	50
7	Long Muzzle Brake	8	.4	.7	200
8	Muzzle Brake	4	.2	.8	50
8	Long Muzzle Brake	8	.4	.65	200
9	Muzzle Brake	4	.2	.75	50
9	Long Muzzle Brake	8	.4	.6	200

Shock Absorbers

TL	*Type*	*L*	*W*	*Rcm*	*Cr*
5	SA Stock**	0	.1	.95	50
7	SA Stock**	0	.2	.9	75
9	Folding SA Stock**	0	.2	.9	150
9	SA Stock**	0	.2	.85	75

Compensators

TL	*Type*	*L*	*W*	*Rcm*	*Cr*
10	Gyroscopic Compensator	0	.5	.5	300
14	Inertial Compensator***	0	1	.3	1000

Action

TL	*Type*	*L*	*W*	*Rcm*	*Cr*
4	Auto or Semiauto*	—	—	.95	—
9	Electrothermal Chemical*	—	—	.6	—

TL: Tech level

L: Length in centimeters

W: Weight in kilograms

Cr: Price in credits

Rcm: Recoil compensator modifier

SA: Shock-absorbing

*Automatic and semiautomatic weapons have a limited built-in recoil compensation system, as some of the weapon's recoil is used (and absorbed) operating the mechanism of the weapon itself. By the same token, electrothermal chemical guns have lower recoil than their muzzle energy would normally indicate and so have what amounts to a built-in recoil reduction. This is automatically included in the weapon and has no additional cost or weight.

**The prices and weights for an SA (shock-absorbing) stock represent the cost to add this mechanism to a conventional stock, and so are in addition to the cost and weight of the stock already fitted. The shock-absorbing feature may usually only be added to solid stocks, not folding stocks. When the folding shock absorbing stock becomes available (TL 9) it may be added to either type of stock.

***The inertial recoil compensator is worn as a harness and the gun is attached to it by a flexible arm. The arm becomes rigid when the weapon is fired and the recoil compensator in the harness pack absorbs much of the force of the recoil. Unlike all other recoil reduction devices, the weight of the inertial compensator is not added to the weight of the weapon (Ww) for purposes of determining recoil weight below.

If a weapon has more than one Rcm, multiply them together to get a single combined value.

If a weapon has no recoil modifiers, its Rcm is 1.

Recoil: Once any recoil compensators have been installed, the weapon's recoil when firing a single shot can be calculated. (Include the weight of a bipod, but *not* a tripod.)

$$R = \{[(0.15\sqrt{E})+Ww] + Em\} \times Rcm$$

R: Recoil number

E: Muzzle energy

Ww: Weight, in kilograms, of weapon (use empty weight for belt- and cassette-fed weapons, loaded weight for all others)

Rcm: Recoil compensator modifier.

Em: Modifier for high muzzle energy. If the weapon has high muzzle energy, add to the final recoil as shown on the chart below.

E	*Em*	*E*	*Em*
1001+	1	10,001+	4
2501+	2	20,001+	5
5001+	3	50,001+	6

When calculating the recoil energy of a burst of shots, the following formula is used:

$$R = (\{[(Bn+2)(0.15\sqrt{E})]+Ww\} + \{[Bn+2]Em\}) \times Rcm$$

Bn = number of shots in the burst.

Bulk: Weapon length is calculated by adding the lengths of all of the individual components. Once the final length of the weapon has been determined, the bulk can be calculated. Bulk is equal to the weapon length (in centimeters) divided by 15, rounding all fractions down.

Volume: Weapon volume, for purposes of installation in a vehicle, is one liter per kilogram of mass (or one cubic meter per tonne).

6. Tinkering the Design

Most of the specifications for the weapon are minimum specifications, and so a weapon can always be heavied up (to reduce its recoil, for instance). This is usually done by adding weight to the receiver. If the weapon has a light receiver, its weight can be increased until it reaches the weight of a heavy receiver for a weapon of that muzzle energy. Once it reaches the weight of a heavy receiver, its weight can only be increased by increasing the length of the receiver. The percentage increase in weight over the weight of a heavy receiver is the percentage increase in length produced by that extra weight.

By the same token, a designer may wish to increase the length of a receiver (to make it possible to use a box magazine, for example). In this case the percentage increase in receiver length is the percentage increase made in receiver weight.

Silencers and Sound Suppressors

True "silencers" are very difficult to construct because, although the sound of the cartridge firing can be muffled, the sound of a supersonic bullet passing through the air cannot, and it is this crack (a mini sonic boom) that is usually heard by hostiles. In fact, many combat soldiers report that they have never heard any weapon firing but their own while in combat, so completely does the mind filter stimuli in a desperate situation, but they regularly hear the passage of hostile bullets.

Sound suppressors effectively muffle the sound of the weapon firing while leaving the sonic crack of the bullets unmodified. This will have no effect on the ability of target personnel to realize that they are under fire or in determining the direction of the fire. What it does do is make it more difficult for personnel not part of the firefight to notice that it is going on. Firefights conducted with suppressed weapons will seldom be heard beyond 500 meters in open countryside or 100 meters in urban areas.

Truly silenced weapons not only muffle the sound of the cartridge firing but also slow the bullet (usually by bleeding off muzzle gas) to sub-sonic speeds. This reduces the sound of the bullet but also considerably reduces muzzle energy. Silenced weapons will not be heard beyond 25 meters in open countryside or five meters in urban areas.

A silenced weapon has its muzzle energy (and as a result its range, damage, and penetration) reduced to that of a weapon of the same caliber but a 15mm straight non-ETC cartridge case. Mounting a standard noise suppressor on a weapon which already fires low-powered cartridges (15mm or less straight non-ETC) and which have a noise suppressor mounted are considered silenced.

Silencer

Length: 1cm per 25 joules of muzzle energy
Weight: 0.025 kg per cm of length
Price: Cr5 per cm of length

Suppressor

Length: 1cm per 100 joules of muzzle energy
Weight: 0.025 kg per cm of length
Price: Cr5 per cm of length

Flash Suppressors

A flash suppressor reduces or eliminates muzzle flash. All firearms have a muzzle flash at night. Weapons with a muzzle energy of 1000 joules or more have a visible daytime muzzle flash when firing from cover or darkened areas (such as woods, buildings, etc.) All weapons with a muzzle energy of 1000 joules or more and a barrel length which is 80% or less have a bright visible muzzle flash in all light conditions.

A flash suppressor will reduce or eliminate muzzle flash, moving the weapon down one "category" for a regular flash suppressor and down two "categories" for a long flash suppressor. A long flash suppressor is twice the length of a regular suppressor.

Flash suppressors may be combined with muzzle brakes by adding the cost of the two together. The total length of the assembly is the length of longer of the two attachments.

Flash Suppressor

Length: 1cm per 300 joules of muzzle energy
Weight: 0.01 kg per cm of length
Price: Cr 1 per cm of length.

Multiple-Barrel Rotary Guns

The design system does not allow for a rate of fire of higher than 10 per barrel due to overheating. However, it is possible to design a multi-barrel weapon which can deliver a higher overall rate of fire. The design sequence follows the above sequence except where specifically noted below.

1. Barrels: The weapon may have as many barrels as desired, but all of them must be identical.

2. Receiver: Rotary guns must have a heavy receiver, and the weight of the receiver is increased by an additional 10% for every barrel. So, for example, a three-barreled gun would have a receiver 130% as massive as a normal heavy receiver of that caliber. This does not increase receiver length, however.

Rate of fire is always equal to 10 times the number of barrels minus 1.

$$ROF = 10\ (Bn-1)$$

Firing characters roll 10 dice for hits at short range, but each rolled hit causes actual hits equal to one less than the number of barrels (Hits = Bn–1). See the **Traveller** rulebook for automatic fire rules and attenuation with range.

3. Feed System: Rotary guns must be cassette- or belt-fed.

Gunshot Wounds

There are few rule mechanics in roleplaying that have generated as much heated discussion as the subject of gunshot wounds and how best to simulate them in a game. The principal reason for this is that, despite the long history of gunshot wounds, interior wound ballistics (the study of what a bullet actually does once it enters a human) have only been subject to careful and systematic study for a few years.

Prior to the last decade, almost all of what we knew about gunshot wounds was anecdotal in nature, based partially on autopsy results (when the wounds were fatal) and partially on the reports of surgeons who treated gunshot wounds, particularly military surgeons. Recently, however, much more systematic study has been done using high-speed photography, test-firing of bullets into blocks of ballistic gelatin (with the same consistency as human tissue), and test-firing into animal carcasses. The U.S. Wound Ballistics Laboratory (WBL), under the direction of Dr. Martin Fackler, has pioneered in this study.

These controlled experiments have gone a long way toward explaining what happens when a bullet enters the human body, and have relegated many of our most cherished beliefs about gunshot wounds to the status of old-wives' tales. A couple of key issues are worth talking about.

Bullet Tumble: Here is a subject about which a huge amount of misinformation has been published. Just recently I picked up an otherwise-reputable source on modern warfare and was told that small-caliber assault rifle bullets (such as from an AK-74 or M-16) actually tumbled through the air, thus causing more dramatic wounds when they hit. Another source didn't go to quite this extreme, but did report that the bullet of the Soviet AK-74 (the 5.45x39mm) is of a very complex design and incorporates an air bubble in the tip of the steel jacket to push the center of gravity back and make it more likely to tumble when it hits its target.

Rubbish.

To begin with, assault rifle bullets do not tumble through the air. Because they are fired from "rifles," they are spin-stabilized and fly straight along their ballistic path. If they tumbled, they would be wildly inaccurate and would lose velocity and energy very quickly.

Second, *all bullets tumble once they hit an obstruction.* I witnessed a convincing demonstration of this conducted by firing various small arms through two paper targets perhaps a meter apart, with the area between them filled with light brush and branches. After firing, the two target were compared. The first target had a perfectly round hole. The second target had an elongated hole (called "key-holing"), meaning that the bullet was beginning to tumble as it passed through it. The demonstration started with small-caliber assault rifles (which everyone knows tumble when they encounter foliage), then demonstrated the same effect with heavier 7.62mm NATO rounds, and wrapped up the show with a Barret .50-caliber sniper rifle. All of the rounds, including the .50-caliber round, began tumbling after hitting the brush.

Third, the impression most people have is that when a bullet tumbles, it does so end-over-end repeatedly. Not so. Dr. Fackler at the WBL has shown repeatedly that when a bullet enters a resisting medium, it will tumble through 180 degrees and then become stable again, exiting the target backwards.

So why does the Russian 5.45x39mm bullet have an air bubble in the tip? About five or six years ago, I had the chance to talk to a representative from the European ammunition firm Dynamit Nobel at a small arms conference. As we talked, it turned out that he had been one of the researchers present when the first examples of 5.56x39mm ammunition captured in Afghanistan had been examined. After carefully cutting open several rounds, their conclusion was that the air bubbles were the result of poor manufacturing techniques. The Soviets simply hadn't been able (or hadn't thought it worth the trouble) to force all of the air out of the tip of the steel jacket when forcing in the lead. From such little things are legends born.

Hydrostatic Shock: For a while it was widely thought that bullets with a sufficiently high muzzle velocity would cause a massive hydrostatic overpressure in the human circulatory system and (in some versions of the theory) explode the heart. Other versions claimed somewhat less dramatic results, but still argued that high-velocity bullets caused massive tissue damage from hydrostatic shock.

Again, the WBL and Dr. Fackler convincingly disproved this. But how can that be? Everyone has seen convincing demonstrations of hydrostatic shock when a bullet is fired into a sealed tin can or sealed water jug and it explodes from the overpressure. Why doesn't the human body behave the same way? Because it is not a tin can.

Instead of being rigidly contained, the human body is extremely flexible and can easily absorb sudden transitory pressure surges. The one place this is less true is the head which, because of the skull, is much less elastic and much more susceptible to hydrostatic shock. Aside from head shots, however, hydrostatic pressure is not the killer it was once thought to be.

Size, Velocity, Energy: What actually injures people? Is it the size of the bullet, its velocity, or its energy? The answer, unfortunately, is "it depends."

Let's start by looking at simple tissue damage. A bullet passing through a target destroys tissue along its path, and it destroys that tissue no matter how fast or how slow it goes (assuming it has enough energy to pass completely through the target). The actual amount of damage done is the volume of the wound cavity, which at first glance might seem to be equal to the diameter of the bullet times the length of the cavity. Not quite. Since all bullets tumble, at some point the bullet actually is travelling sideways and it is at that point that most of the serious damage is done. A better measure of a bullet's damage is found by multiplying its diameter by its length. Long bullets (such as those fired from rifles) are much more damaging than the shorter bullets fired from pistols.

But if all that matters is bullet dimensions, what's all the fuss about muzzle energy? The answer is that bullet dimensions are important determinants of *tissue* damage, assuming that's all that the bullet hits. But if the bullet hits bone, bullet energy becomes critical. A low-energy bullet will often ricochet off the bone, sometimes exiting the wound and doing very little damage. A high-energy bullet, on the other hand, will shatter the bone, continue on its course, and send bone fragments through the body as additional tissue-destroying projectiles.

We wanted a fairly simple means of calculating bullet damage, and so chose to base it exclusively around muzzle energy, for three reasons. First, whenever bone is hit (which is fairly often), energy is the main cause of damage. Second, when tissue is hit, a certain minimum muzzle energy is necessary to force the bullet through the target and cause maximum tissue damage, and so even here energy serves as a cap on damage. Third, bullet dimensions (the main cause of tissue damage) are directly related to bullet mass, and, except in very unusual cases, larger bullets have higher muzzle energies.

CHAPTER 2
Gauss Weapons

Conventional small arms accelerate projectiles using the force of expanding gases from an explosion. These weapons are inherently limited by the rate of expansion of the exploding gases and, as noted before, have a practical upper limit on muzzle velocity of about 2000 meters per second.

Electromagnetic weapons, however, have no such limits. These weapons use electric energy to power electromagnets which accelerate projectiles down the barrel of the gun. For these weapons, the practical upper limit of muzzle velocity in the atmosphere is 6400 meters per second. Projectiles moving faster than that will burn up from atmospheric friction. There is no real limit to muzzle velocity in a vacuum, but most electromagnetic weapons are designed for work on a planetary surface and so are designed within the limits of atmospheric operation.

Electromagnetic small arms (2cm and smaller in bore) are called gauss weapons (as opposed to mass drivers, which refers to larger-bore electromagnetic weapons). Gauss weapons can be built in the same configurations as other small arms: pistols, carbines, rifles, and autoguns.

One additional advantage that gauss weapons have over conventional small arms is the lack of barrel friction. Conventional small arms push the bullet out of the barrel by means of expanding explosive gases (or an expanding plasma in the case of ETC rounds). The bullet must be a tight fit in the barrel in order to contain the high-pressure gases behind it, and this means that there is considerable friction between the bullet and the barrel wall. Not only is this energy-inefficient, it generates a great deal of heat. In fact, very little barrel heat is generated by the heat of the propellant explosion; almost all of it is simple friction.

Since a gauss weapon does not rely on a tight gas seal to push the round, the bullet is in only light contact with the barrel as it moves down it and so generates very little friction. This allows a weapon to sustain a much higher rate of fire and to do so without resorting to multiple gun barrels. As a result, most gauss autoguns are usually called VRF gauss guns, the VRF standing for very rapid fire.

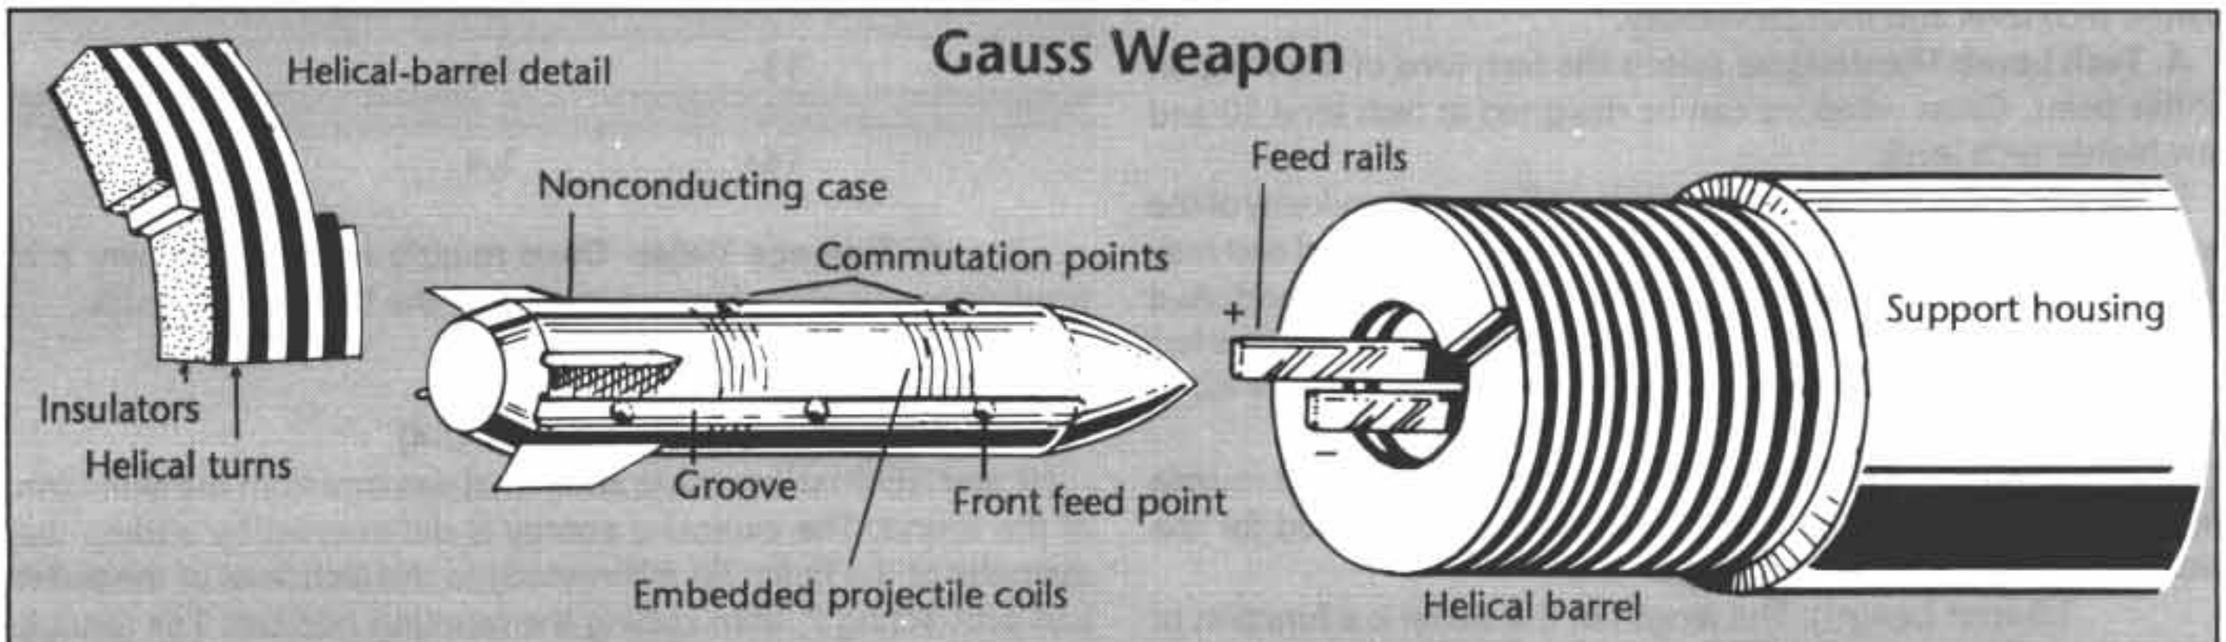
Gauss weapons consist of four principal components: a barrel, power source, homopolar generator, and stock or mount.

The barrel consists of a series of concentric metallic rings which are the actual magnetic propellers for the round. These magnets are fired in sequence and accelerate the bullet down the barrel. The ring magnets are usually covered with a protective housing.

The weapon's power source can be any conventional supply of electricity, and is dictated more by the size of weapon and its likely use than by any unique requirements of the electromagnetic process. Weapons mounted on vehicles often draw on the vehicle's power plant for energy, while man-portable weapons rely on batteries.

Regardless of the means of power generation, a homopolar generator is necessary to store the energy until it reaches sufficient density to power the gun (and until the gunner wishes to fire), and then feeds the energy back in one rapid burst of power. One advantage of the tremendous torque generated by the rapid discharge of the HPG is that it can be used to gyroscopically counter part of the weapon's powerful recoil.

Gauss weapons use stocks and mounts similar to conventional small arms, and are very similar in appearance to such weapons.



Gauss Ammunition Design

Like other small arms, the first step in designing a gauss weapon is to design its bullet. As the bullet is a simple finned dart, however, this is much simpler than with other small arms ammunition.

The only defining characteristic of gauss ammunition is its caliber, expressed in millimeters. Although standard weapons listed in the game are usually in increments of 0.5 millimeters (such as 5.5mm, 7.5mm, etc.) weapons may be designed in any caliber desired, such as 11.43mm or 4.71mm. Small arms gauss weapons may be made in any caliber up to 20mm. (Weapons of 20mm and above are usually considered to be cannons and are covered under Mass Drivers, pages 110-111.) All gauss bullets have a length equal to their diameter multiplied by 5.

Once the size of the round has been specified, determine its weight.

Gauss Weapon

A slotted copper alloy coil magnet is arrayed to form the barrel of the gauss gun so that current flows through the entire array along one continuous helical path.

The bullet has two projectile coils set into its outer casing (which is itself nonconducting), grooves in the side to fit electrical rails which run along the inside sides of the gun barrel, feed contact points in the grooves, and commutation contact points attached to the coils. The feed contact points set in the bullet grooves allow direct current to pass from the positive left rail into the rear projectile coil and then exit the bullet through the rear coil's commutation contact point into the main magnetic coil. The current then flows along the coil of the magnet until it reenters the bullet's front coil by way of the front coil's commutation contact point and exits the bullet by way of the front feed contact point into the negative rail. In this way, the current moves up the barrel with the projectile, continuously accelerating it.

Weight: The ammunition weight (Wa) in grams is determined using the following formula:

$$Wa = .04\,\pi r^2$$

r: Radius (in millimeters) of the bullet (half the diameter).

π: 3.1416

Price: The price of the ammunition is determined by the following formula:

$$Cr = WaTm$$

Cr: Price in credits

Wa: Weight of the round in grams

Tm: Type multiplier, as determined below:

Type	*Tm*
Mass-produced military ammo	0.02
Conventional	0.04

Special Ammunition

The above design sequence deals with solid slug ammunition, called "dart" ammunition for gauss weapons. A variety of special small arms ammunition is available as well.

HE: HE, or high-explosive, ammunition is hollow and contains an explosive filler that detonates on impact.

Price for HE rounds is multiplied by 2.

HEAP: HEAP, or high-explosive, armor-piercing, bullets are hollow, as with HE bullets, but have small shaped charges for penetrating armor.

Price for HEAP rounds is multiplied by 3.

Tranq: Tranq rounds are nonlethal means of subduing adversaries. These are fired at lower-than-usual velocities, to avoid lethality.

Price for Tranq rounds is multiplied by 2.

WEAPON DESIGN

1. Barrel

The barrel of a gauss weapon is a major component of the weapon and is much more sophisticated in design and construction that the barrel of a conventional small arm. Once ammunition has been selected, two design decisions determine everything else about the barrel: tech level and muzzle velocity.

A. Tech Level: The designer selects the tech level of the weapon at this point. Gauss weapons can be designed at tech level 10 and any higher tech level.

B. Muzzle Velocity: The designer selects the muzzle velocity of the weapon. Muzzle velocity is expressed in meters per second and may be any velocity up to a maximum of 6000 meters per second. As a practical matter, gauss small arms rarely have muzzle velocities less than 1500 meters per second or much in excess of 3000 or 4000 meters per second.

C. Evaluation: Based on ammunition size, tech level, and muzzle velocity, a number of important variables are determined for the weapon that are used in later steps.

1.Barrel Length: The length of the barrel is a function of tech level and muzzle velocity. Higher velocities require longer barrels to provide the necessary acceleration, while advances in technology allow higher acceleration in shorter distances (thus allowing shorter barrels). Barrel length is determined using the following formula:

$$Lb = V+100TLm$$

Lb: Length of barrel in centimeters.

V: Muzzle velocity in meters per second. (Step 1-B)

TLm: Tech level multiplier, as shown in the next column:

TL	*TLm*
10	1.6
11	1.3
12	1.0
13	0.8
14	0.6
16+	0.4

2. Barrel Weight: The weight of the barrel is determined using the following formula:

$$Wb = .03Lb$$

Wb: Weight (in kilograms) of a barrel.

Lb: Length (in centimeters) of the barrel. (Step 1-C-1)

3. Barrel Price: The price of the barrel is determined using the following formula:

$$Cr = Wb600$$

Cr: Price of the barrel in credits.

Wb: Weight of the barrel in kilograms (Step 1-C-2)

4. Muzzle Energy: The muzzle energy of the weapon is determined using the following formula:

$$E = (0.5MV^2)+1000$$

E: Muzzle energy in joules

M: Bullet mass in grams

V: Muzzle velocity in meters per second (Step 1-B)

Tranq rounds are assumed to have lower muzzle velocities, but this is handled in the Damage Value (Step 1-C-6) and Range (Step 3-A) sections below, and so is not calculated separately.

5. Required Energy: The energy required to accelerate the bullet to the desired muzzle velocity is a function of the total generated muzzle energy, and the efficiency of the weapon in converting electrical power quickly to magnetic force (which is a function of tech level). The required energy (in joules) is equal to the weapon's muzzle energy multiplied by the weapon's tech level efficiency, as shown on the following table.

TL	*Efficiency*
10	3
11	2.4
12	2
13	1.8
14	1.6
16+	1.4

6. Damage Value: Once muzzle energy is known, it is possible to calculate damage and using the following formula.

$$D = (\sqrt{E})+15$$

D: Damage value

E: Muzzle energy (in joules) (Step 1-C-4)

HE and HEAP bullets cause additional damage from the explosion of the round. The explosive energy is determined by adding the diameter of the bullet (in millimeters) to the tech level of the bullet and subtracting 7, then cubing the resulting number. The result is the explosive energy of the bullet. When calculating damage, the value for E in the formula becomes the sum of muzzle energy and explosive energy.

All Tranq rounds have a damage value of –1*, indicating that they do 1D6–1 points of damage plus the special tranq effect discussed on page 350 of the basic **Traveller** rules.

7. Penetration: It is also possible to determine penetration once muzzle energy is known by consulting the following table:

E	*Pen*
0-1000	Nil
1001-3000	1-Nil
3001-5000	1-2-Nil
5001-10,000	1-3-5
10,001-20,000	1-2-4
20,001-50,000	2-2-3
50,001+	2-2-2

For HEAP ammunition, penetration is always 2-2-2.
For HE and Tranq ammunition, penetration is always Nil.

2. Receiver

The receiver of a gauss weapon serves a function somewhat different from that of a conventional small arm. As in a conventional weapon, the gauss weapon's receiver "receives" the bullet from the magazine and aligns it with the barrel for firing. There is no mechanical bolt, firing pin, or ignition chamber, however, as the acceleration of the round takes place exclusively in the barrel. Therefore, the receiver houses only the magazine feed system and the internal homopolar generator.

A. Receiver Type: All gauss receivers are of the self-loading variety. The receiver may be semiautomatic (single shot, ROF code of SA) or selective fire (capable of semiautomatic and full automatic fire) at the designer's option.

B. Rate of Fire: If selective fire, designer must specify the automatic rate of fire, 5, 10, or 50. If either ROF 5 or 10 is chosen, the weapon is normal selective fire. If both 5 and 10 are chosen, it is a multi-selective fire weapon. If the rate of fire is 50, the weapon is called a VRF (very rapid fire) gauss weapon.

A listed ROF of 5/10 means that the weapon is multi-selective fire and can be fired as a semiautomatic weapon, an automatic weapon with an ROF of 5, or an automatic weapon with an ROF of 10.

C. Evaluation: Based on receiver type and barrel information, a number of important variables are determined for the weapon.

1. Receiver Weight: The receiver weight is dependent largely on the energy of the weapon and the efficiency of homopolar generators available at that tech level. Receiver weight is determined by the following formula:

$$Wr = PTm$$

Wr: Weight of the receiver in kilograms
P: Required power joules (Step 1-C-5)
Tm: Tech level modifier as shown below.

TL	*Tm*
10	0.00016
11	0.00012
12	0.00010
13	0.00009
14	0.00008
15	0.00007
16	0.00006
17	0.00005
18	0.00004
19	0.00003
20	0.00002
21	0.00001

If capable of fully automatic fire (with a rate of fire of either 5 or 10), multiply the receiver weight by 1.1. If multi-selective fire (capable of both automatic ROFs 5 and 10), multiply the receiver weight by 1.2. If a VRF weapon (rate of fire of 50), multiply the receiver weight by 5.

2. Receiver Length: The length of the receiver is determined by the following formula:

$$Lr = \sqrt{1000Wr}$$

Lr: Length of the receiver in centimeters
Wr: Weight of the receiver in kilograms (Step 2-C-1)
However, the receiver may never be shorter than the length of one bullet.

3. Receiver Price: The price of the receiver in credits is equal to its weight in kilograms (Step 2-C-1) multiplied by 100. If capable of selective fire (one automatic rate), multiply price by 1.2.

3. Stocks

Stocks refer to rifle stocks and pistol grips. The desired stock for the weapon is selected from the following table. Note that carbine stocks are generally fitted to rifles with short barrels (up to 80% of the average barrel length for the cartridge) or sport versions of rifles. They are not considered sturdy enough for full-length rifles in military use. Weapons intended to fire exclusively from vehicle mounts and/or tripods only require a pistol grip.

TL	*Type*	*L (cm)*	*M (kg)*	*Cr*
4	Pistol grip	0	0.2	5
5	Hollow pistol grip	0	0.1	25
7	Rifle stock	25	0.5	30
7	Bullpup rifle stock	5	0.1	10

A. Range: Once the type of stock is known, the weapon's range can be calculated according to the following formula:

$$SR = (\sqrt{E})\ Cm$$

SR: Short range in meters of a weapon
E: Muzzle energy in joules (Step 1-C-4)
Cm: Configuration modifier, as shown below. If two configuration descriptions apply to the same weapon, multiply them together to determine the total configuration multiplier.

Configuration	*Cm*
Bullpup	1.1
One-handed	0.5
Two-handed*	1.6

* Two-handed refers to weapons specifically designed to be fired with two hands, and thus including a stock instead of simply a pistol grip. However, weapons with only a pistol grip but fired exclusively from a tripod or fixed/vehicle mount count as two-handed weapons.

Tranq Ammunition: Multiply range calculated above by 0.6 for tranq ammunition, but short range is never more than 30 or less than 4 meters regardless of the calculated value.

HE and HEAP Ammunition: Multiply range calculated above by 0.75 for HE and HEAP ammunitions.

Maximum Range: Regardless of the results of this calculation or any modifications made later (through the addition of sights or mounts), the upper limit on the short range of gauss weapons is 300 meters.

4. Feed System

The feed system is the method by which individual rounds are stored in the weapon fed to the receiver. Gauss weapon magazines are more complex than conventional small arms magazines since they hold, in addition to the bullets themselves, a battery capable of powering the weapon for the number of shots contained in the magazine.

A. Battery Weight: The weight of the battery in a magazine is a function of the number of rounds in the magazine, the required energy of the weapon, and the weapon's tech level. The battery weight is determined using the following formula:

Wb = NErTm

Wb: Weight of battery in kilograms.
N: Number of rounds the magazine is designed to hold.
Er: Required energy in joules.
Tm: Tech level modifier, as shown below:

TL	*Tm*
10	.00001
11	.000009
12	.000006
13	.0000055
14	.000004
15	.0000035
16	.000003

B. Magazine Type: Gauss weapons can be fed by grip magazines, box magazines, or cassettes. VRF weapons are usually fed from cassettes, but it is possible to design a large-capacity box magazine which can also feed such a weapon.

Grip Magazine: Grip magazines are small box magazines inserted through a hollow pistol grip.

The maximum length of bullets in a grip magazine is 60mm. The maximum number of rounds that can be carried in a grip magazine is equal to 140 divided by the diameter (in millimeters) of an individual round. The capacity, however, applies only to magazines which fit completely inside the pistol grip. Weapons which are never holstered (such as submachineguns) may have longer magazines. The maximum ammo length still applies, but the capacity of the magazine otherwise is determined as for a box magazine.

Box Magazine: A box magazine is a spring-loaded metallic or plastic box which is attached to the receiver. A weapon may only be fed by a box magazine if its receiver is at least 150mm longer than the length of the cartridge fired by the weapon.

Cassette: A cassette is a pre-packaged container of ammunition attached to an endless link feed system which moves the ammunition to the weapon. Cassette feed systems are usually electrically powered either by the batteries or by a vehicle engine.

C. Magazine Evaluation: Once the battery weight and magazine type have been determined, the following information can be determined:

1. Magazine Weight: The weight of an empty magazine (grip magazine or box magazine) is determined by the following formula.

Wm = .0006(N+4)Wa + Wb

Wm: Weight (in kilograms) of an empty magazine.
Wa: Weight (in grams) of a complete round of ammunition.
N: Number of rounds the magazine is designed to hold.
Wb: Weight of battery.

An empty cassette feed system weighs 2 kilograms plus the weight of the battery for the ammunition contained in it. Due to the basic overhead cost of the power and feed system, cassettes seldom hold fewer than 1000 rounds.

2. Magazine Price: Empty box or grip magazines cost Cr2 per kilogram, rounding fractions up. Empty cassettes cost Cr10 per kilogram, rounding fractions up.

3. Loaded Magazine Weight: A loaded magazine weighs the amount shown above plus the weight of the individual rounds loaded into it.

5. Options

Once the basic mechanical components of the weapon have been designed, a number of optional features may be added.

A. Sights: The basic ranges calculated above assume traditional iron sights. All of the more advanced sights listed below are available at all tech levels at which gauss weapons may be constructed.

Optic sights are rugged military versions of telescopic sights, which do not provide the same long-range benefits of those sights but which do improve accuracy. Optic sights provide a multiplier to the weapon's short range, as shown on the chart below.

Telescopic or electronic sights may only be installed on two-handed weapons and provide a base addition to the short range instead of a multiplication. This short range is the weapon's short range *before* being multiplied by the optic sight modifier.

A laser sight allows up to three shots fired during a turn to count as aimed shots (instead of only the first one). All other shots fired during the turn count as quick shots. The sight may only be used at ranges up to its maximum listed range.

ADVANCED SIGHTS

Type	*Range (m)*	*Mass (kg)*	*Price (Cr)*
Optic	×1.15	0.1	150
Telescopic	+15	0.1	200
Electronic	+20	0.2	2000
Laser	240	0.5	300

B. Recoil Reduction: There are two types of devices used to reduce recoil on gauss weapons: shock absorbers and compensators. No more than one of each type may be added to the weapon. Some weapons enjoy lower recoil because of the type of action employed, and these are treated as a separate fourth type of recoil reduction.

SHOCK ABSORBERS

TL	*Type*	*L*	*W*	*Rcm*	*Cr*
9	Folding SA Stock*	0	.2	.9	150
9	SA Stock*	0	.2	.85	75

COMPENSATORS

TL	*Type*	*L*	*W*	*Rcm*	*Cr*
10	Gyroscopic Compensator	0	.5	.5	300
14	Inertial Compensator**	0	1	.3	1000

TL: Tech level
L: Length in centimeters
W: Weight in kilograms
Cr: Price in credits
Rcm: Recoil compensator modifier
SA: Shock-absorbing

* The prices and weights for an SA (shock-absorbing) stock represent the cost to add this mechanism to a conventional stock, and so are in addition to the cost and weight of the stock already fitted.

** The inertial recoil compensator is worn as a harness and the gun it attached to it by a flexible arm. The arm becomes rigid when the weapon is fired and the recoil compensator in the harness pack absorbs much of the force of the recoil. Unlike all other recoil reduction devices, the weight of the inertial compensator is not added to the weight of the weapon (Ww) for purposes of determining recoil weight below.

If a weapon has more than one Rcm, multiply them together to get a single combined value.

If a weapon has no recoil modifiers, its Rcm is 1.

C. Mounts: Bipods and tripods may be provided for weapons. Tripods may be of any weight desired, but the highest base recoil number of the weapon (usually attained when firing a burst) may not be greater than the weight of the tripod in kilograms. Bipods are usually custom-built for weapons, and their weight is determined using the following formula.

Wbp = .0005E (but never less than 1 kg)

Wbp: Weight (in kilograms) of the bipod

E: Muzzle energy (in joules)

The price of tripods is determined by the following formula:

Cr = 100 + (10W)

Cr: Price in credits.

W: Weight in kilograms.

The price of bipods is determined by the following formula:

Cr = 50 + (10W)

Cr: Price in credits.

W: Weight in kilograms.

Recoil: The recoil of a weapon when fired from a bipod is the standard value (as determined below) times 0.5. The recoil of a weapon when fired from a tripod is the standard value times 0.25. When calculating the weapon's weight to compute recoil in F-1 below, the weight of a bipod (if the weapon is equipped with one) is added into the weapon's weight, but not the weight of a tripod.

Range: Bipods and tripods extend the range of the weapon, as shown on the following table (all vehicle-mounted weapons also receive the tripod modifier).

Mount	*Range*
Bipod	×1.3
Tripod	×2.0

D. Bayonet Lugs: Bayonet lugs are simple standardized brackets at the end of the weapon barrel. A bayonet lug costs nothing and has negligible mass, but must be specified as part of the design.

A bayonet is less useful than a hand-held knife unless it is mounted on a well-balanced weapon with sufficient length to allow it to be used as a spear point. As a result, only weapons with a bulk (see below) of 4 or more may profitably benefit from a bayonet lug. Shorter weapons may have them but the mounted bayonet counts as a short-range (instead of long-range) melee weapon and suffers a +1 Diff Mod for its chance to hit in armed melee combat.

E. Grenade Adapter: A grenade adapter allows the firing of rifle grenades and adds 5 cm to the length of the weapon and costs Cr50.

F. Silenced: A gauss weapon makes very little sound normally as there is no explosive detonation of propellant. The only sound is the sound of the bullet travelling at supersonic speeds. Consequently, all gauss weapons are treated as having sound suppressors. In addition, a gauss weapon can be designed with the capability to reduce barrel coil power sufficiently to fire at subsonic velocities and thus be truly silenced. This option doubles the cost of the weapon's receiver, but has no effect on weapon weight or length.

If this option is selected, it is necessary to recalculate weapon muzzle energy, damage, penetration, and range, all based on a muzzle velocity of 300 meters per second.

The weapon can fire either standard ammunition or special low-powered ammunition designed to meet the lower power requirements that come with the lower muzzle velocity.

G. Tinkering: Most of the specifications for the weapon are minimum specifications, and so a weapon can always be heavied up (to reduce its recoil, for instance). This is usually done by adding weight to the receiver. Receiver weight can only be increased by increasing the length of the receiver. The percentage increase in weight over the design weight of a receiver is the percentage increase in length produced by that extra weight.

By the same token, a designer may wish to increase the length of a receiver (to make it possible to use a box magazine, for example). In this case the percentage increase in receiver length is the percentage increase made in receiver weight.

These changes in receiver weight and length do not change the price of the receiver.

H. Evaluation: Once the above optional features have been decided on two additional items of information can be determined.

1. Recoil: The weapon's recoil when firing a single shot can be calculated using the following formula:

$$\mathbf{R = \{[(0.15\sqrt{E})+Ww] + Em\} \times (0.5Rcm)}$$

R: Recoil number

E: Muzzle energy

Ww: Weight, in kilograms, of weapon (use empty weight for belt- and cassette-fed weapons, loaded weight for all others)

Rcm: Recoil compensator modifier.

Em: Modifier for high muzzle energy. If the weapon has high muzzle energy, add to the final recoil as shown on the chart below.

E	*Em*	*E*	*Em*
1001+	1	10,001+	4
2501+	2	20,001+	5
5001+	3	50,001+	6

When calculating the recoil energy of a burst of shots, the following formula is used:

$$\mathbf{R = (\{[(Bn+2)(0.15\sqrt{E})]+Ww\} + \{[Bn+2]Em\}) \times (0.5Rcm)}$$

Bn = number of shots in the burst.

Mounts: The recoil of a weapon when fired from a bipod is the standard value times 0.5. The recoil of a weapon when fired from a tripod is the standard value times 0.25.

2. Bulk: Determine the final length of the weapon by adding together the lengths of the individual components. Bulk is equal to the weapon length (in centimeters) divided by 15, rounding all fractions down.

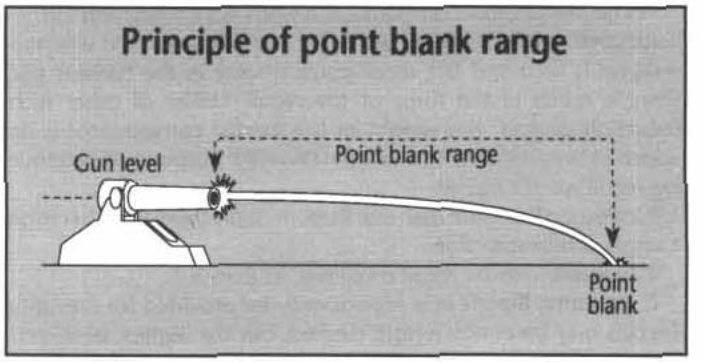
CHAPTER 3

1 Chemically Propelled Round (CPR) Guns

CPR guns are the large-bore equivalent of conventional small arms. They work using the same physical laws and have many of the same physical limits, although on a grander scale. The principle is simple: An explosion is contained at one end of a tube. The expanding gases of the explosion escape the only direction possible—down the tube, forcing a solid projectile out ahead of them. The tube is often (but not always) rifled, imparting spin to the projectile to stabilize it in flight. Modern CPR guns which are not rifled fire projectiles which rely on small fins at the rear of the projectile for stability, much like a rocket does. Current armor-piercing ammunition fired by the smoothbore gun of the M1A1 tank is called APFSDS, or armor-piercing, fin-stabilized, discarding-sabot ammunition.

In general terms, designing CPR guns is a simple proposition. The longer the barrel, the greater the muzzle velocity possible, up to the practical limits of the round. The greater the muzzle velocity, the greater the range and, given a constant projectile weight, the greater the muzzle energy. The greater the muzzle energy, the more recoil generated, and hence the more massive a carriage required to absorb that recoil. There are a number of sticky design problems which gun designers have had to overcome over the course of time.

Muzzle Energy: As muzzle energy is a recurring theme in gun design, now is a good time to discuss it. Muzzle energy is simply the energy of a projectile at the moment it leaves the muzzle of a gun. We chose that particular instant because it is the peak energy of the projectile. All the time it is travelling down the barrel, it is accelerating. The instant it leaves the barrel, the expanding gases of the exploded propellant charge cease acting on it and it immediately begins to slow due to atmospheric drag (or, in a vacuum, continues to coast at a constant velocity). Therefore, the projectile will never have more energy than it has at the instant it leaves the muzzle.



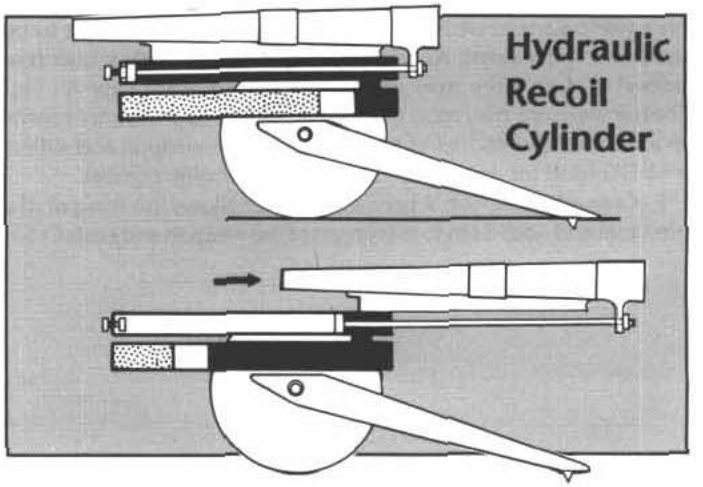
Muzzle energy is very easy to calculate if the projectile mass and the muzzle velocity are known, as energy is a simple function of mass and velocity. The formula is: Energy equals one-half mass times velocity squared.

$$E = (0.5M)V^2$$

Traveller uses the metric system of measurements, and so the units used in this equation are joules (energy), kilograms (mass), and meters per second (velocity). Since most calculations in CPR gun design use megajoules (1 million joules), convert the result of the above equation to megajoules (Mj) by dividing by 1,000,000.

Effective Range: There are a number of ways of measuring effective range, and as good a way as any is the range at which a gun will hit its intended target more than half the time. Since modern ammunition experiences very little deflection, hitting a target is largely a function of correctly determining the range.

Just as a round begins to decelerate as soon as it leaves the muzzle, so also does it begin to fall (assuming it is fired in a gravity well). If the weapon is pointed straight ahead and level to the ground, the distance at which a shot fired will impact the ground is dependent on the muzzle velocity of the round. This is so because a round dropped from muzzle level and a round fired at the same time will both hit the ground at the same time, since both are falling toward the ground at exactly the same rate. Therefore, the higher the muzzle velocity, the farther the round will travel from the gun before hitting the ground.



This distance, by the way, is called the gun's "point blank" range, and within that range estimates of distance are considerably less important. Usually you have a good chance of hitting a target by simply pointing at it and firing. Beyond point blank range, however, the story is more complicated. For the round to hit, the gunner has to aim above the target. If the gunner aims too low, the round will hit the ground before it reaches the target; if the gunner aims too high, it will pass over the target. Therefore, knowing the correct angle of elevation depends on knowing, as accurately as possible, the exact range.

The importance of muzzle velocity points to another advantage of subcaliber rounds such as APDS. As these rounds are lighter, the same propellant energy produces a higher muzzle velocity, and thus a more accurate and long-ranged gun. In general, then, the higher the muzzle velocity of a weapon the longer its effective range, but rangefinders and ballistic computers play a major supporting role in determining the actual chance of a hit.

Recoil: Absorbing the recoil energy of a firing gun is the function of its carriage. In the case of armored vehicles, the vehicle itself is the carriage, although some form of recoil absorbers are usually necessary to avoid damaging the vehicle when the gun fires.

The carriage serves to keep the gun in place while it fires. To avoid damaging the carriage from the recoil force, some means of recoil compensation is usually mounted. Truly modern artillery dates from tech level 4 with the introduction of on-carriage recoil absorbers, which allow quicker firing of the gun as well as much more powerful guns and movable carriages.

The recoil absorber is most often a hydraulic compensator; as the gun fires, it recoils on the carriage in a slide cradle, the recoil energy partly being absorbed by the rearward movement of the gun and partly absorbed by the carriage, braced against the ground. The

rearward motion is slowed and the force absorbed by a hydraulic piston in an oil-filled cylinder (or two or three cylinders on larger weapons). This hydraulic recoil compensator is often called a recuperator, since the stored recoil energy in the hydraulic piston is then used to move the gun back forward in its slide cradle on the carriage to its firing position.

Recoil, and the carriage weight necessary to deal with it, is a critical variable in gun design, especially with regard to vehicle-mounted weapons. The heavier the vehicle, the slower it tends to be, as the hardly mobile German Hunting Tiger illustrates. Because of modern ammunition, which gets more penetration out of a particular amount of muzzle energy, the gun of the M1A2 Abrams has almost three times the penetration of the Hunting Tiger's gun while generating only 75% as much muzzle energy. The lower muzzle energy means a less powerful recoil, less massive gun system, and much more mobile vehicle.

When examining the muzzle energies generated by some of the larger guns, it should become clear why they required specially built railway carriages, not only to fire, but also to serve as large recoil slides.

CPR GUN DESIGN SEQUENCE

This design sequence covers "modern" artillery, from tech level 4 on, which fires chemically propelled rounds (CPR). A CPR gun fires a projectile which is propelled by the expansion of gases in a chemical explosion.

A. Specifications

The characteristics of CPR guns are determined by six specifications. In addition, the weapon's muzzle energy is used through the rest of the design sequence and is calculated at this time.

1. Tech Level: Select a tech level appropriate to the world where the gun was built.

2. Bore Size: Bore size, also known as caliber, is the diameter of the gun's bore. The smallest CPR gun has a bore diameter of 2cm. (Anything smaller than this is considered a small arm.) The CPR Gun table lists bore sizes in increments of centimeters, but intermediary sizes may be selected as well, such as 2.4cm or 9.1cm.

3. Barrel Length: Barrel length is usually expressed as a length in calibers. That is, a 2 cm gun with a barrel seventy calibers long would be (2×70=140) 140 centimeters long. Barrels may be of any length desired up to 100 calibers. As a general rule of thumb, howitzers tend to be about 30 calibers long while high velocity guns tend to be about 60-70 calibers long.

The gun is usually identified by its bore size in millimeters (cm × 10) followed by its length in calibers, either separated by a slash or the letter "L," as in "20/70" or "20L70."

4. Fire Control: The type and tech level of fire control equipment must be specified. Fire control equipment is available for direct fire, indirect fire, and point defense. A gun may have more than one type. See Section 14.

5. Mount: A gun is mounted either on a carriage or directly on a vehicle.

6. Options: A gun may have a gun shield if desired, which provides the crew some protection against fragmentation and small arms fire from the front. At tech level 6 and above, a gun may have mechanical assistance for the loaders, which will speed reloading.

7. Muzzle Energy: The CPR Gun table (page 109) lists the muzzle energy, in megajoules (Mj), of each bore size gun assuming a barrel length of 60 calibers. For bore sizes which fall between those listed on the table, use interpolation to find the correct muzzle energy.

For every caliber in length longer than 60, increase the muzzle energy by 1%.

For every caliber less than 60, reduce the muzzle energy by 2%, until the weapon reaches 20 calibers in length. For every caliber in length less than 20 calibers, reduce the muzzle energy by 1%.

When this calculation is completed, multiply the result by the tech level multiplier found on the CPR Gun Tech Level table below.

CPR Gun Tech Level

TL	*ME Tech Mult.*
4	×0.8
5-6	×1
7	×1.2
8	×1.4
9+	×1.6

B. Weight

The complete weapon system weight is equal to the weight of the gun itself, plus its fire control equipment, plus its carriage (unless vehicle-mounted), plus its gun shield (if any), plus its mechanical loader (if any).

1. Gun Weight: Consult the CPR Gun table (page 109) and read the weapon weight (in tonnes). The weight on the table assumes a 60-caliber gun. Increase or decrease the weight by 1% for each caliber change in length up or down. A gun 25 calibers long, for example, is 35 calibers less than 60, and so would weighs (100–35=) 65% of the weight shown on the table.

A 20L70 gun would weigh 110% of the weight shown on the table. Since the listed weight of a 2cm gun is 0.1 tonnes, the gun weighs 0.11 tonnes, or 110 kilograms.

If the bore size falls between two bore sizes on the table, interpolate the correct value.

2. Fire Control: The weights of the various fire control systems are given in the Fire Control chapter (Section 14).

3. Carriage Weight: The carriage weight of a gun, in tonnes, is its muzzle energy in megajoules divided by 2, but is never less than the weight of the gun itself.

Vehicle-mounted guns do not require carriages, but the vehicle itself must weigh at least twice the required carriage weight.

4. Gun Shield: The weight of a gun shield in tonnes is equal to 0.07 times the bore size in centimeters.

5. Mechanical Loading Assistance: The weight of mechanical loading assistance is equal to the gun weight × 0.1.

6. Autoloaders: Autoloaders are available for vehicle-mounted weapons. These have a weight equal to 30 times the weight of a single round for the weapon.

C. Gun Crew

The number of crewmen required to man a gun depends on its function and how it is mounted. A crew normally consists of a gunner and several loaders. Indirect fire weapons usually include a gun commander as well.

1. Indirect Fire: The crew required to serve a towed (carriage-mounted) indirect fire weapon is equal to its bore size in centimeters. Vehicle-mounted weapons require a crew half this size, rounding fractions up, but never less than two. Vehicle-mounted weapons equipped with autoloaders require a crew of only one (the gunner).

2. Direct Fire: The crew required to serve a towed (carriage-mounted) direct fire weapon is equal to its bore size in centimeters divided by 3, rounding fractions up. Vehicle-mounted weapons require a crew half this size, rounding fractions up, but never less than two. Vehicle-mounted weapons equipped with autoloaders require a crew of only one (the gunner).

D. Range

Weapons have four direct fire ranges: short, medium, long, and extreme. If fitted with indirect fire control equipment, they also have an indirect fire range.

1. Direct Fire Range: Direct fire range is mostly a function of the muzzle velocity of a weapon, which is largely determined by its barrel length. A secondary consideration is the size of the round, as larger rounds lose velocity from drag more slowly than do smaller rounds. A tertiary consideration is the type of ammunition fired, as some ammunition is fired at lower muzzle velocities.

Short direct fire range in meters for a CPR gun firing a kinetic penetrator round (AP, HVAP, APDS, etc.) is equal to the 5 times the sum of its bore size in centimeters plus its barrel length in calibers plus 20. [R = 5 (B+L+20)]

Hypervelocity smoothbore guns available at TL 7 and higher generate higher muzzle velocities with shorter barrel lengths. To reflect this, multiply range by the following TL modifiers:

TL	*Modifier*
7	1.15
8	1.3
9+	1.45

Short direct fire range for all other types of rounds (HE, HEAP, APERS, etc.) is equal to the above range multiplied by 0.75.

Note, however, that the type of direct fire gun sights mounted impose an upper limit on the short range of a direct fire weapon.

2. Indirect Fire Range: To calculate indirect fire range in kilometers, multiply the square root of the weapon's bore (in centimeters) by its barrel length (in calibers) by 0.13. At each tech level above 4 of the gun, add 1 to barrel length for this calculation.

For BB (base bleed) ammunition (see the Munitions chapter, beginning on page 135), multiply the range by 1.2.

For RAP (rocket-assisted projectile) ammunition (also see the Munitions chapter, page 135), multiply the range by 1.5.

E. Reloading

The time the weapon requires to reload is a function of its muzzle energy and any mechanical assistance provided. The base number of five-second turns required to load a round is equal to its muzzle energy (in megajoules), rounding fractions to the nearest whole number (but always rounding fractional values less than 1 up to 1).

Mechanical assistance provides a multiplier which has the effect of reducing the muzzle energy for purposes of this calculation, as shown on the Mechanical Loading Assistance table.

Mechanical Loading Assistance

TL	*Multiplier*
6	.9
7	.7
8	.5
9+	.3

Note that autoloaders, if installed, do not increase this rate, but only allow loading crew to be dispensed with.

F. Price

The price of the weapon is equal to the sum of the price of its components. Fire control equipment costs as listed in the Fire Control chapter (Section 14). The prices of other components are determined by their weights and cost multipliers, as shown below.

Component	*Cost Multiplier*
Gun Tube	0.02
Carriage	0.002
Loading Assistance	0.01
Autoloader	0.01
Gun Shield	0.001

Cost Multiplier: Cost of each component in millions of credits is equal to its weight in tonnes (calculated earlier) times the appropriate cost multiplier.

G. Set-Up

All CPR guns must be set up before they can conduct indirect fire, and towed CPR guns must be set up before they can conduct any kind of fire. It takes longer to set up for indirect fire, given the need for precise surveying and positioning, and towed weapons naturally take longer than self-propelled weapons.

The time, in five-second combat turns, needed to set up a towed CPR gun for indirect fire is equal to the gun's bore size in centimeters times 8 (round to the nearest whole number).

The number of turns to set up a self-propelled gun for indirect fire is equal to its bore size in centimeters times 4.

The number of turns to set up a towed gun for direct fire is equal to its bore size in centimeters times 4.

Self-propelled indirect fire guns with land navigation systems of tech level 8 or higher (see the Controls chapter, Section 4) require even less time, equal to the gun's bore size in centimeters times 2.

H. Volume

The volume of CPR gun in cubic meters, for purposes of transportation or mounting in a vehicle, is equal to its mass in tonnes.

SPECIAL CASES

The following weapons are special cases or variants of standard CPR guns.

1. Autocannon

Autocannons are self-loading CPR guns which fire more than one round per combat turn, much like an overgrown machinegun.

A. Specifications: The largest allowed bore size for an autocannon at tech level 4 is 2cm. Add 2cm to the largest allowed bore size for each tech level higher than 4. There are two additional specifications for autocannons:

1. Action: An autocannon may have either a recoil-operated or an electric-operated action. Electric actions are not available until tech level 7.

2. Number of Barrels: An autocannon may have from one to eight barrels.

B. Weight: The weight of the weapons system includes the additional weight of its action, any additional barrels, and its magazine. A recoil-operated action weighs the same as a single-barrel gun. An electric action weighs 0.3 times the weight of a single-barrel gun. Every additional barrel in excess of one weighs 0.3 times the weight of a single-barrel gun.

The carriage weight of the gun, in tonnes, is its muzzle energy in megajoules multiplied by the gun's rate of fire and then divided by 4, but is never less than the weight of the gun itself.

Vehicle-mounted autocannons do not require carriages, but the vehicle itself must weigh at least twice the required carriage weight.

C. Crew: The crew of an autocannon is usually one, although additional crewmen may be present to assist in changing magazines.

D. Price: Price is calculated the same as for a regular CPR gun. The cost multiplier for a recoil-operated action is 0.003, and the cost multiplier or an electric action is 0.01.

E. ROF: The base rate of fire per barrel is 40 divided by the bore diameter in centimeters. For multiple barrel guns, multiply this by number of barrels and divide by 2.

F. Magazine: The magazine may be any size desired by the player. The weight of the empty magazine is equal to the weight of all the rounds carried multiplied by 0.01. The price of an empty magazine in Cr is equal to its weight in kilograms multiplied by 5. The volume of a magazine in cubic meters is equal to the mass in tonnes of the rounds carried by the magazine + 2.

G. Reload Time: Reload time to change the magazine, in complete five-second turns, is equal to the loaded weight of a magazine, in tonnes, multiplied by 10, rounding fractions up. The number of loaders needed is equal to the mass of a loaded magazine in tonnes multiplied by 10, rounding fractions to the nearest whole number.

2. Mortars

Mortars are a specialized category of CPR guns designed to be lightweight, low velocity, high-angle indirect fire weapons. They have no direct fire ability at all, and are usually drop-fired (that is, a round is dropped down the muzzle and strikes a fixed firing pin at the bottom of the gun tube), eliminating the need for a heavy breach block. They are designed using the CPR gun design sequence with the following exceptions:

A. Specifications: No mortar may be more than 20 calibers in length. Mortars never have gun shields or direct fire control. They may have mechanical loader assistance.

B. Weight: Multiply gun weight by 0.6 and carriage weight by 0.3.

C. Reloading: Halve the reloading time of the mortar, rounding fractions up.

D. Set-Up: The indirect fire set-up time for the mortar is calculated as if it were its direct fire set-up time. Mortars do not engage in direct fire and so there is no direct fire set-up time. (Note that this means that mortars take half as long to come into action as indirect fire guns of the same bore size).

3. Electrothermal-Chemical Guns

Electrothermal-chemical (ETC) guns are not technically CPR guns because their rounds are not "propelled by the expansion of gases in a chemical explosion." Instead, their rounds are propelled by a rapidly expanding high-temperature plasma. As a result, they are also called combustion-augmented plasma (CAP) guns. However, their design is otherwise so similar as to invite inclusion here as a special case of CPR guns. The only exceptions to the normal CPR design sequence are noted below.

A. Specifications: ETC guns are available from tech level 9 on. They must be specified as ETC guns in the design sequence. Instead of using the muzzle energy tech multiplier on the CPR Gun Tech Level table, multiply muzzle energy by 2.5, regardless of tech level.

B. Electrical Input: ETC guns use an intense pulse of electrical energy to ignite the working fluid into plasma, so a source of pulsed energy must be provided. Multiply the ETC muzzle energy (from A above) by 0.06 to find the amount of energy, in megajoules, required per round fired. The weapon must have a capacitor/homopolar generator installed with this capacity (see Power Production, Section 8). The weight of the HPG becomes part of the total weight of the weapon.

The gun also needs a power supply. Multiply the required energy per round fired in megajoules (this is equal to the capacity of the HPG) by the gun's rate of fire (for autocannons, in rounds per 5-second turn; for slower-firing weapons in fractions of rounds per five-second turn, e.g., one round every three turns equals 0.33 rounds per turn) to get megajoules required per turn. Divide this result by 5. The result is the number of megawatts that must be allocated to the ETC gun from the vehicle's power plant.

C. Weight: For ETC guns, carriage weight is muzzle energy divided by 3.

D. Range: For ETC guns, triple the indirect fire range. BB and RAP rounds may not be fired from electrothermal guns.

CPR Gun Table

Bore (cm)	*Gun Weight (tonnes)*	*Gun Muzzle Energy (Mj)*
2	.10	.06
3	.12	.15
4	.16	.35
5	.30	.8

35	40	230
40	50	350
45	60	500

CHAPTER 4
Mass Drivers

A mass driver is nothing more than the electromagnetic equivalent of artillery. It is a gauss weapon with a bore of 2cm or more. This means that it is mounted on a vehicle or carriage instead of being hand-held, and it means that it is often powered by a separate power plant instead of batteries in a magazine. But these difference notwithstanding, its basic operating principles are identical to those of a gauss rifle.

A. Specifications

The characteristics of mass drivers are determined by six specifications. In addition, the weapon's muzzle energy and required power are used through the rest of the design sequence and are calculated at this time.

1. Tech Level: Select a tech level appropriate to the world where the gun was built. Mass drivers may be built from tech level 8 on.

2. Muzzle Velocity: Muzzle velocity at tech level 8 is 3000 meters per second, and this increases by 1000 meters per second per tech level until reaching a maximum of 6000 meters per second at TL 11.

3. Projectile: The projectile is defined by its diameter in centimeters. This is also the bore of the weapon.

The mass of the projectile is calculated using the following formula:

$$Mp = (\pi r^3)+10$$

Mp: Mass of projectile in kilograms
π: 3.1416
r: Radius of the bore (bore diameter divided by 2) in centimeters

4. Fire Control: The type and tech level of fire control equipment must be specified. Fire control equipment is available for direct fire, indirect fire, and point defense. A gun may have more than one type. See Section 14.

5. Mount: A gun is mounted either on a carriage or directly on a vehicle.

6. Options: A gun may have a gun shield if desired, which provides the crew some protection against fragmentation and small arms fire from the front. If vehicle-mounted, the gun may also have an autoloader.

7. Muzzle Energy: Once the muzzle velocity and the projectile weight are known, the muzzle energy can be calculated using the following formula:

$$Em = 0.0000005MV^2$$

Em: Muzzle energy in megajoules
M: Projectile mass in kilograms
V: Muzzle velocity in meters per second

8. Required Energy: The energy required to accelerate the projectile to the desired muzzle velocity is a function of the total generated muzzle energy and the efficiency of the weapon in converting electrical power quickly to magnetic force (which is a function of tech level). The required energy (in joules) is equal to the weapon's muzzle energy multiplied by the weapon's tech level efficiency, as shown on the following table.

TL	*Efficiency*
8	4.5
9	3.6
10	3
11	2.4
12	2
13	1.8
14	1.6
16+	1.4

B. Weight

The complete weapon system weight is equal to the weight of the gun itself, plus its homopolar generator, plus its fire control equipment, plus its carriage (unless vehicle-mounted), plus its gun shield (if any), plus its autoloader (if any).

1. Gun Weight: The weight of the gun is determined by the following formula:

$$Wg = D^2+50$$

Wg: Weight of gun in metric tonnes
D: Bore diameter in centimeters

2. Homopolar Generator Weight: The efficiency by tech level of HPGs is shown in the Power Production chapter (Section 8). The mass driver requires an HPG with a capacity in megajoules equal to the energy requirement of the gun.

3. Fire Control: The weights of the various fire control systems are given in the Fire Control chapter (Section 14).

4. Carriage Weight: The carriage weight of a gun, in tonnes, is its muzzle energy in megajoules divided by 4, but is never less than the weight of the gun itself.

Vehicle-mounted guns do not require carriages, but the vehicle itself must weigh at least twice the required carriage weight.

5. Gun Shield: The weight of a gun shield in tonnes is equal to 0.07 times the bore size in centimeters.

6. Autoloader: The weight of the autoloader is equal to 30 times the weight of a single round.

C. Gun Crew

The number of crewmen required to man a gun depends on its function and how it is mounted. A crew normally consists of a gunner and several loaders. Indirect fire weapons usually include a gun commander as well.

1. Indirect Fire: The crew required to serve a towed (carriage-mounted) indirect fire weapon is equal to its bore size in centimeters divided by 2, rounding fractions up. Vehicle-mounted weapons require a crew half this size, rounding fractions up, but never less than two. Vehicle-mounted weapons equipped with autoloaders require a crew of only one (the gunner).

2. Direct Fire: The crew required to serve a towed (carriage-mounted) direct fire weapon is equal to its bore size divided by 5, rounding fractions up. Vehicle-mounted weapons require a crew half this size, rounding fractions up, but never less than two. Vehicle-mounted weapons equipped with autoloaders require a crew of only one (the gunner).

D. Range

Weapons have four direct fire ranges: short, medium, long, and extreme. If fitted with indirect fire control equipment, they also have an indirect fire range.

1. Direct Fire Range: Direct fire range is mostly a function of the muzzle velocity of a weapon. A secondary consideration is the size of the round, as larger rounds lose velocity from drag more slowly than do smaller rounds. A tertiary consideration is the type of ammunition fired, as some ammunition is fired at lower muzzle velocities.

Short direct fire range in meters for a mass driver gun firing a kinetic penetrator round is equal to the sum of the bore diameter (in centimeters) and the muzzle velocity (in meters per second) all multiplied by .015.

Short direct fire range for all other types of rounds (HE, HEAP, APERS, etc.) is equal to the above range multiplied by 0.75.

However, short range may not exceed the limit imposed by the installed direct fire sights (Fire Control chapter, Section 14).

2. Indirect Fire Range: To calculate indirect fire range in kilometers, multiply the square root of the weapon's bore (in centimeters) by its muzzle velocity (in meters per second) by 0.004.

E. Reloading

The time in complete five-second combat turns the weapon requires to reload is a function of its projectile weight and any mechanical assistance provided. The base number of five-second turns required to load a round is equal to its projectile weight (in kilograms) divided by 2, rounding fractions to the nearest whole number. A result of less than 0.5 (which rounds down to 0) indicates that a round can be reloaded in the same combat turn in which the weapon fires, leaving it capable of firing again in the next combat turn.

If an autoloader is available, multiply projectile weight by 0.3 for purposes of this calculation.

F. Power Requirement

The amount of power required to operate a mass driver is based on its required energy, determined in step A, and its reload time, derived in step E immediately above.

The reload time establishes the weapon's rate of fire. Add 1 to the reload time to find the number of turns required for each shot. (For example, a mass driver that requires two turns to reload fires on turn one, spends turns two and three reloading, and then fires again on turn four. Thus it fires once every three turns.) The lowest possible result is one turn. Take the rate of fire in combat turns and multiply by 5 to find the rate of fire in seconds required to fire each round.

Now take the required energy in megajoules (from step A-8) and divide it by the number of seconds required to fire a round. The result is the required power (in megawatts) that must be supplied to the mass driver to allow it to operate.

$$Pr = Er \div S$$

Pr: Required power input (megawatts)
Er: Required energy (megajoules)
S: Number of seconds required for each shot

G. Price

The price of the weapon is equal to the price of its components. Fire control equipment and homopolar generators cost as listed in the Power Production and Fire Control chapters (Sections 8 and 14, respectively). The prices of other components are determined by their weights and cost multipliers, as shown below.

Component	*Cost Multiplier*
Gun Tube	0.05
Carriage	0.002
Autoloader	0.01
Gun Shield	0.001

Cost Multiplier: Cost of a component in millions of credits equals its mass in tonnes times the cost multiplier.

H. Set-Up

All guns must be set up before they can conduct indirect fire, and towed guns must be set up before they can conduct any kind of fire. It takes longer to set up for indirect fire, given the need for precise surveying and positioning, and towed weapons naturally take longer than self-propelled weapons.

The time, in five-second combat turns, needed to set up a towed gun for indirect fire is equal to the gun's bore size in centimeters times 8 (round to the nearest whole number).

The number of turns to set up a self-propelled gun for indirect fire is equal to its bore size in centimeters times 4.

The number of turns to set up a towed gun for direct fire is equal to its bore size in centimeters times 4.

Self-propelled indirect fire guns with land navigation systems of tech level 8 or higher (see the Controls chapter, Section 4) require even less time, equal to the gun's bore size in centimeters times 2.

I. Volume

The volume of a mass driver gun in cubic meters, for purposes of transportation or mounting in a vehicle, is equal to its mass in metric tonnes.

Autocannon

The following weapons constitute a special case or variant of standard mass driver guns. Autocannons are mass drivers which fire more than one round per combat turn, much like an overgrown machinegun. Procedures for autocannon design are the same as normal mass driver design, with the modifications below.

A. Bore Size: The largest allowed bore size for an autocannon at tech level 8 is 10cm. Add 2cm to the largest allowed bore size for each tech level higher than 8.

B. Weight: The weight of the weapon system includes the normal weight of a weapon of that bore size plus the additional weight of its automatic feed action and its magazine.

The weapon's feed action is the loading mechanism which feeds additional rounds into the breach. Its weight is equal to the weight of a single projectile for the gun multiplied by 50.

The carriage weight of the gun, in tonnes, is its muzzle energy in megajoules multiplied by the gun's rate of fire and then divided by 4, but is never less than the weight of the gun itself.

C. Crew: The crew of an autocannon is usually one, although additional crewmen may be present to assist in changing magazines.

D. Price: Price is calculated the same as for a regular mass driver gun. The cost multiplier for the feed action is 0.01.

E. ROF: The base rate of fire per barrel is 50 divided by the bore diameter in centimeters. For single-barrel guns, this is the final ROF. For multiple-barrel guns, multiply this base rate by the number of barrels and divide by 2 to get the final ROF.

F. Power Requirement: Take the autocannon's ROF determined immediately above and multiply it by the required energy per shot in megajoules. This yields the total energy required per combat turn. Divide this by 5 to find its constant power requirement in megawatts.

$$Pr = (ROF \times Er) \div 5$$

Pr: Required power input (megawatts)
ROF: Rate of fire per five-second combat turn
Er: Required energy (megajoules)

G. Magazine: The magazine may be any size desired by the player. The weight of the empty magazine is equal to the weight of all the rounds carried multiplied by 0.01. The price of an empty magazine in Cr is equal to its weight in kilograms multiplied by 5. The volume of magazine in cubic meters is equal to the mass in tonnes of the rounds carried by the magazine ÷ 5.

H. Reload Time: Reload time to change the magazine, in complete five-second turns, is equal to the loaded weight of a magazine, in metric tonnes, multiplied by 10, rounding fractions up.

The number of loaders needed is equal to the mass of a loaded magazine in tonnes multiplied by 10, rounding fractions to the nearest whole number.

CHAPTER 5

Particle Accelerator Weapons (PAWs)

The first charged particle accelerators are available at tech level 8, with the more useful neutral particle beam weapons appearing one level later. Particle accelerators use powerful electrical and/or magnetic fields to accelerate ions or charged subatomic particles to relativistic speeds (close enough to the speed of light that the particles exhibit a measurable increase in mass compared to their rest mass). These same fields are used to focus these particles into concentrated beams that retain their power density over long distances. Because neutral (chargeless) particles cannot be affected by electrical or magnetic fields, these particles must be charged while they are accelerated. However, they do not have to be charged after they leave the barrel of the accelerator. Neutral particles are created by having a device (a screen of foil or gas, or a high-powered laser) that strips the extra electron from a negative ion (thus making a negative hydrogen ion into a neutral atom) as it passes out of the barrel, or adds an electron to a positive ion. (Note that neutral particle beam weapons do not fire neutrons, as there is no way to accelerate a neutron, nor could positive or negative charges be stripped away from neutrons without particle decay.) Charged particle beams are fired by simply allowing the charged particles to fly out toward the target.

This is important, because charged particle accelerator weapons (C-PAWs) propagate fairly well through atmospheres (where the flow of like charges in the same direction behaves like an electrical current and generates a magnetic field around itself that "pinches" the beam together), but effectively disintegrate in vacuum, where the like charges in the beam repel each other, destroying beam focus and integrity. On the other hand, neutral particle accelerator weapons (N-PAWs) perform flawlessly in space, as the neutral atoms proceed unperturbed by magnetic or electrical fields. In atmospheres, however, the N-PAW beam breaks up rapidly, as there is no electrical current to provide coherence, and the atmosphere ionizes, absorbs, and otherwise degrades the particle beam. Thus, N-PAWs are the space weapons and C-PAWs are the ground weapons. But because a neutral particle beam weapon can produce charged particle beams simply by disengaging its particle neutralizer, the N-PAW is effectively a dual-purpose weapon, as it can be set to fire beams appropriate to either environment. PAWs intended purely for ground use can forego the needless expense of the particle neutralizer and are therefore single-use weapons.

Dual-purpose or not, however, particle accelerators have a problem with planetary bombardment. A ship firing a C-PAW from outside of an atmospheric envelope will find that the beam severely scatters before it enters the atmosphere, often so badly that it does not have enough coherence to create its self-pinching tunnel. Ships with dual-purpose particle weapons must often enter the atmosphere in order to fire C-PAWs at surface targets.

Although particle accelerators can be curved (typical modern particle accelerators used for research are huge rings), for military purposes, curved particle accelerators are inefficient because of the need to keep the particles moving in a circular path (i.e., constantly adding transverse acceleration to keep them in a curving path). Not only does this waste energy that could be spent to increase linear acceleration, but such designs are far more vulnerable to damage than linear designs. While the loss of power to an accelerator coil in a linear design would decrease overall acceleration, loss of an accelerator coil in a ring design would result in particles leaving the circular path. Thus, combat particle accelerators are linear accelerators, built as long tubes.

Because of the need for a long straight run to properly accelerate and aim the pulses of particles, a particle accelerator must be long and straight in order to be most effective.

PARTICLE ACCELERATOR WEAPON SYSTEM DESIGN

1. ACCELERATOR TUNNEL LENGTH

Tunnel length aboard ship is defined by the type of installation and the size of the ship the gun is to be fitted to. Ground mounted PAWs can be built to any length desired, within normal cost, facility, and power constraints.

Spaceship installations are of three types: spinal, parallel, and bay.

1A. Spinal Mounts

As the name implies, a spinal mount gun serves as the central internal-strength member of the entire ship. The gun defines the longitudinal axis of the ship, as well as its axis of mass and thrust. The length of a spinal mount is equal to the length of the ship (in meters) as defined during the spacecraft hull design step. Spacecraft with an open frame hull form may not have a spinal mount.

The spinal mount can be installed to fire either dead ahead (this is the standard configuration) or dead astern (called the "stern chaser" configuration). Its arc of fire is therefore either 1 or 5 (see Spacecraft Design Evaluation, page 16).

Each ship may have only one spinal weapons mount. The one exception to this is the so-called "Janus" mount, in which two spinal guns are installed in the spinal tube butted against each other, one pointing forward and one astern, where each is half the total length of the ship.

1B. Parallel Mounts

Parallel mounts, like spinal mounts, are mounted directly fore and aft, parallel to the ship's spine. Unlike spinal mounts, there can be more than one per ship.

The length of a parallel mount is 0.8 times the length of the ship in meters. They may be installed to fire either directly forward into fire arc 1, or dead astern into fire arc 5.

Ships with a sphere hull form may make a slightly different use of parallel mounts. Rather than being restricted to mounting parallel mounts along the fore-and-aft axis, a sphere's dimension allows the installation of parallel mounts athwartships, firing broadside, or at any other angle off of the centerline. These mounts are designed just as normal parallel mounts, but may be installed to fire into any one arc of fire, not just 1 or 5.

1C. Bay Mounts

PAWs may also be mounted in bays set into the hull surface. There is no limit to the number of bays that can be fitted to a ship, beyond the normal limits of hull surface area, mass, and volume.

A bay may be constructed to any size desired, although the most popular are the 50-ton (700 cubic meters) and 100-ton (1400 cubic meter) bays. A bay's dimensions are calculated as follows:

Each bay has a single long dimension and two shorter dimensions. The long dimension, in meters, is found by taking the bay's volume in cubic meters, extracting the cube root, multiplying by 1.4, and rounding to the nearest whole number.

$$1.4\sqrt[3]{Vol}$$

Divide the bay's total volume in cubic meters by the long dimension, and extract the square root of this result, rounding to the nearest 0.5 meters. This is the approximate length of the bay's short dimensions. Multiply the long dimension by the short dimension to get the surface area of the bay in square meters.

Standard Bays and their Dimensions

Size	*Cubic Meters*	*Long Dim.*	*Short Dim.*	*Surface Area*
50 ton	700	12 m	7.5 m	91.2 m^2
100 ton	1400	16 m	9.5 m	150.4 m^2

The length of the accelerator tunnel is the long dimension of the bay.

2. ACCELERATOR TUNNEL CROSS-SECTIONAL AREA

Accelerator performance is also dependent on its cross-sectional area, i.e., the space within which the electromagnetic coils bend and focus the paths of the particles. The cross-sectional area is also called the tunnel's focal area. Like laser beams, particle beams can be more tightly focused by larger focal areas.

Define the diameter of the accelerator tunnel in meters, and find its surface area based on this number, using the formula

Area (square meters) = πr^2

where r (meters) = diameter ÷ 2, and π = 3.1416

Limits to tunnel diameter include total space available to the PAW (bay-mounted PAWs must fit completely within the volume of the bay), and the length of the tunnel. Tunnel diameter may not be greater than actual tunnel length times 0.125.

3. DISCHARGE ENERGY

Specify the amount of output energy that will be fired in each shot (*discharge energy*, abbreviated DE) in megajoules (Mj). The greater the discharge energy, the greater the damage of each shot, and the greater the final size of the particle accelerator installation.

The maximum discharge energy is limited by the length of the accelerator tunnel. DE in Mj cannot be greater than the square of tunnel length in meters.

4. ACCELERATOR TUNNEL CHARACTERISTICS

Find effective tunnel length, effective focal area, tunnel volume, tunnel mass, and tunnel price based on tunnel length in meters, discharge energy, and the table below. The table shows the tunnel length multiplier, focal area multiplier, and mass multiplier by tech level.

The column for C-PAWs is for single-purpose, charged-particle only weapons; N-PAWs is for dual-purpose, neutral/charged particle beam weapons.

Accelerator Tunnel Characteristics

		FA Multiplier		
TL	*Length Multiplier*	*C-PAW*	*N-PAW*	*Mass Multiplier*
8	0.12	1	—	1.2
9	0.14	1	1	1.0
10	0.16	2	1	1.0
11	0.2	3	2	0.75
12	0.25	3	3	0.75
13	0.3	4	3	0.75
14	0.5	4	4	0.75
15	1.0	5	4	0.75
16	1.25	5	5	0.6
17	1.3	5	5	0.5
18	1.4	6	5	0.4
19	1.5	6	6	0.4
20	1.6	6	6	0.3
21	1.7	6	6	0.3
22	1.8	7	6	0.2
23	1.9	7	7	0.2
24	2.0	7	7	0.1

4A. Tunnel Effective Length

The effective length (meters) of the accelerator tunnel increases with tech level and is used in calculating range performance below. 1

Effective Length = actual tunnel length (meters)×length multiplier

4B. Effective Focal Area

The effective area (square meters) of the tunnel focal area (same as its cross-sectional area) increases with tech level and is also used in calculating range performance below. 2

Effective Focal Area (square meters) = actual cross-sectional area (in square meters, from Step 2 above) × FA multiplier appropriate to type of PAW. 3

4C. Tunnel Volume

Tunnel Volume (cubic meters) = actual length (meters) × actual cross-sectional area (square meters) from Step 2. 4

4D. Tunnel Mass

Tunnel Mass (tonnes) = tunnel volume (cubic meters) × mass multiplier. 5

4E. Tunnel Price

Tunnel price depends on whether the weapon is an N-PAW (dual-purpose, neutral/charged beam capable) or single-purpose C-PAW. 6

C-PAW Tunnel Price (MCr) = tunnel volume (cubic meters) × 0.09 at all tech levels.

N-PAW Tunnel Price (MCr) = tunnel volume (cubic meters) × 0.1 at all tech levels. 7

Tunnel price is calculated after any increase in size due to high rates of fire (Step 8C, below)

5. PERFORMANCE 8

The effective range (range at which energy delivered on target is equal to discharge energy) in kilometers is equal to the effective tunnel length (meters) × effective focal area × 1000.

Beyond this range, the beam's performance drops due to the gradual expansion of beam width over distance which results in the lowering of beam intensity per unit area of the beam's "footprint." 9

For space combat range in hexes/range bands, divide this result by 30,000. It is usually best to drop fractions in order to find the range best suited for the weapon's short range. However, these may be rounded up to the higher value if the designer is prepared to accept the potential drop in damage performance due to the higher range (see Step 7B, below). 10 11

5A. Atmospheric Performance

All particle beam energy is eventually absorbed by planetary atmospheres. The effective range defined above is the accelerator's theoretical effective range. For neutral particle beams, this theoretical effective range is achieved in vacuum: in space or on the surface of airless worlds. For charged particle beams, this theoretical effective range can never be reached; C-PAWs have their effective range modified for fire in vacuum as well as in atmospheres. 12 13

When the accelerator is to be used within atmospheres, the following modifications must be made to its effective range, which controls its damage performance. Although theoretically a PAW might be rated for its performance in all potential atmospheres, in practice it need only be rated for the environment for which it was originally intended, for example the atmosphere of the world on which it was designed, or in vacuum for a starship N-PAW. 14

Atmospheric Range Modifiers

Atmosphere (UWP Code)	N-PAW (Firing Neutral Beam)	C-PAW (Any PAW firing Charged Beam)
Vacuum (0)	1	0.001
Trace (1)	1	0.005
Very Thin (2, 3)	0.1	0.01
Thin (4, 5)	0.02	0.05
Standard (6, 7)	0.01	0.1
Dense (8, 9)	0.005	0.1
Exotic+ (A+)	0.001	0.05

Effective range as adjusted by atmosphere can be used in different ways according to the purposes of the designer. If the accelerator is a C-PAW intended for use in an atmosphere, the atmosphere adjusted effective range should probably be used when choosing a beam pointer (Step 6, immediately following). If it is an N-PAW intended for space combat, its unadjusted effective range should be used to choose the beam pointer.

Planetary Bombardment: This is a specific application of the atmospheric modifier rules. This is not calculated in advance for each particle weapon, but is calculated separately each time it is done.

First find the range to the world being bombarded, in hexes. Planetary bombardments from the same hex are given a default value of 0.5 hexes. Divide this range by the atmosphere modifier appropriate to the atmosphere type and PAW type from the table above. The result is the equivalent range in hexes to a target on the planetary surface, called the *atmosphere adjusted range.* Use this range to find the proper range band of the PAWs rated range performance. If the range falls between two range bands, use the higher band. This gives the weapon's damage performance. Difficulty of the firing task is still calculated according to the actual range.

If the adjusted range falls beyond the PAW's extreme range, use the PAW's effective range along with the procedure defined in Step 7B below to determine if the PAW has any damage performance left at that range.

If the target is an aircraft or spacecraft flying at high altitude, cut this final atmosphere adjusted range in half.

5B. Magnetic Fields

Charged particle beams also run into difficulties when fired at, on, and around worlds that possess a magnetic field. All firing tasks are one difficulty level higher.

6. DEFINE SHORT RANGE

Select a beam pointer from the Beam Pointer table (Fire Control chapter, Section 14) based on the PAW's tech level and the range performance desired. Note that range is given in kilometers and 30,000-km hexes/range bands for space combat. The listed range in km/hexes will be the weapon's short range for purposes of combat.

Whenever possible, the beam pointer range should be equal to the weapon's effective range to take full advantage of its range-intensity performance. If the beam pointer range is less than the effective range, the PAW will not have the maximum possible hit probability out to its maximum beam intensity (although the absolute upper limit of beam pointer short range is 300,000 km/10 hexes). If the beam pointer range is longer than the effective range, the PAW will not deliver its maximum damage performance at its best hit probability. However, these decisions are up to the designer.

When a particle accelerator has its performance adjusted for atmosphere, remember that its atmosphere-adjusted ranges are for purposes of damage calculation only. Its short range (and medium, long, and extreme ranges which are derived from it) based on installed beam pointers are still used for resolving hits.

7. COMBAT RATINGS

7A. Combat Range Bands

All combat ranges are based on the PAW's short range, established in Step 6. For planet-bound C-PAWs, these ranges should be expressed in kilometers; for space-based N-PAWs, these ranges should be expressed in starship combat hexes/range bands in whole numbers.

Medium range = Short range × 2
Long range = Short range × 4
Extreme range = Short range × 8

7B. Damage Value

Define the particle accelerator's damage characteristics at its short, medium, long, and extreme range bands.

Particle accelerators do damage to enemy targets based on their *penetration value* (PV).

$$PV = 5\sqrt{I}$$

where I is the weapon's *intensity* (units for intensity are MJ per square centimeter) at that range. Intensity is derived as follows:

For each of the four range bands, divide that range band's actual range (from 7A, in kilometers or hexes, as appropriate to the type of weapon) by the PAW's effective range (in the same units) from Step 5. Round this result to the nearest 0.01. This figure is used as R in the next formula:

$$I = DE (1 + R^2)$$

where
DE is discharge energy from Step 3 above.

8. POWER REQUIREMENTS

8A. Input Energy

Particle accelerators have a 20% energy efficiency, meaning that of the energy put into each shot, 20% is projected toward the enemy in the form of the particle beam. The remaining 80% is spent ionizing, accelerating, and magnetically aiming, and in N-PAWs, neutralizing, the particles.

Find input energy in MJ according to this formula:

Input Energy (IE) = Discharge Energy (DE) + 0.2

8B. Homopolar Generator

A particle accelerator requires a homopolar generator (HPG) to store the energy required for each shot until that energy is ready to be expended as a pulse. The HPG's volume is calculated by multiplying the accelerator's input energy (IE) in MJ determined above by the value on the HPG table in the Power Production chapter (Section 8).

8C. Rate of Fire

Select the PAW's rate of fire (ROF).

Space Combat: N-PAWs, intended to be used for space combat, must have an ROF of at least 10 shots per 30-minute space combat turn. Higher rates gain reductions in difficulty level according to the table below. Due to the tremendous energies generated by each shot, which must be dissipated during the cooling/purge cycle, the maximum ROF of a standard particle accelerator is 100 shots per 30-minute turn. Rates of fire above this level require that the PAW be "beefed up" to stand up to the higher usage rate. The amount of this beefing up is expressed on the following table as a multiplier to the the PAW's volume. This increase in volume does not change its tunnel cross-sectional area or effective focal area, but does affect its weight and price.

To convert space to planetary ROFs, divide the space combat ROF per 30 minutes by 360. Take the inverse (i.e., divide 1 by that number), and round fractions *up*. The result is the number of five-

second combat turns required for each shot. Express this number as a fraction, i.e., one shot every five turns is 1/5, one shot every 36 turns is 1/36, etc. Because this conversion system results in distortion of total number of shots due to rounding, this converted ROF must never be used when calculating power input. The original space combat ROF must always be used when rating a space combat meson gun.

Diff Mods on the following table apply to space combat only, not ground combat.

Rate of Fire Benefits in Space Combat

Space Combat ROF (Shots per 30-minute turn)	*Benefit (In Diff Mods to Fire Task)*	*Vol Mod*	*Ground Combat ROF (Shots per 5-second turn)*
10	None	×1	1/36
50	–1 Difficulty levels	×1*	1/8
100	–2 Difficulty levels	×1*	1/4
200	–3 Difficulty levels	×1.3	1/2
400	–4 Difficulty levels	×1.7	1
800	–5 Difficulty levels	×2.2	2

*There is no penalty for firing a particle accelerator at one of these higher power levels if it is mounted in a vehicle or starship which is designed from the outset to provide sufficient power for the higher ROF (50 or 100 shots). However, PAWs which were not installed with the higher power levels may fire at these levels if sufficient power is made available by diverting it from other systems. However, because of the extra strain this places on power couplings, HPGs, etc., an Engineering task must be rolled each turn this is attempted (roll using crew quality). The difficulty level is Difficult if the ROF is raised one step (from 10 to 50 or from 50 to 100) over the installed power allocation, or Formidable if raised two steps (10 to 100). Failure at this roll indicates a System Reset result (see the **TNE** Space Combat chapter, or **Brilliant Lances: Traveller Starship Combat**), with the additional penalty that the PAW may not fire on the current turn. Catastrophic Failure indicates more severe damage. Roll 1D10: 1-5 indicates a Degraded Performance result in addition to System Reset, 6-10 indicates a Major Hit on the particle accelerator.

PAWs may only fire at the 200+ ROFs if they are designed as such with beefed-up focal arrays.

Planetary Combat: ROF for planetary combat C-PAWs is defined in terms of five-second planetary combat turns. The maximum rate of fire for planetary combat is one shot every fourth turn (expressed as 1/4), due to the need for a cooling cycle following each shot.

8D. Power Input

Power input in megawatts (MW) is calculated differently for space combat and planetary combat purposes. Although they are calculated differently, space and planetary combat power input values are absolute values, as they are both based on MW input per second. However, be careful to make these calculations based on the *true* ROF for the accelerator, based on its primary environment: space or planetary combat. Do not use ROFs converted from one system to the other, as the rounding involved distorts the numbers.

Space Combat (Neutral) PAWs: Multiply ROF per 30 minutes times input energy (IE) from Step 7A. This is the total number of megajoules needed over the course of a 30-minute turn. Divide this result by 1800 to find the MW of power that must be allocated to operate the weapon.

Planetary Combat (Charged) PAWs: Multiply ROF times input energy (IE) from Step 7A. This is the total number of megajoules consumed by the weapon each five-second turn. Divide this result by 5 to find the MW of power that must be allocated to operate the weapon.

9. GUN CREW AND WORKSTATIONS

All particle accelerators must be crewed according to the following formula:

Crew = (Tunnel Volume ÷ 100) × CP

CP: Computer multiplier based on tech level of computer installed aboard ship/hooked up to ground-based PAW. See Computers table in the Controls chapter (Section 4).

Round to the nearest whole number, but results of less than 1 must always be rounded up to 1.

Each crewmember must have a gunner's (normal) workstation installed with characteristics obtained from the Controls Chapter (Section 4).

10. PARTICLE ACCELERATOR CARRIAGE, MOUNT, ETC.

If the accelerator is a starship- or vehicle-mounted N-PAW, skip this step. If it is a C-PAW intended for use as a towed weapon, calculate the size of its carriage, mount, etc. A towed carriage has the same mass as the C-PAWs mounted on it. The PAW must include its HPG, but may be plugged in to a power source at its destination.

Carriage-mounted PAWs have an all-around armor value of 1. This can be increased by enclosing the PAW and its supporting equipment in a "hull" (cylinder hull form) with a certain thickness of armor according to the vehicle or spacecraft design rules. As this armor increases the mass of the PAW, it will increase the mass of the carriage as well.

The price of the carriage, in MCr, is equal to its mass in tonnes multiplied by 0.002.

11. PARTICLE ACCELERATOR PHYSICAL CHARACTERISTICS

Add up or bring down the above components to obtain the following total figures for the gun.

11A. Volume

In cubic meters. Add tunnel volume, beam pointer volume, HPG volume, gunner's workstation volume, carriage volume (if any).

11B. Mass

In tonnes. Add tunnel mass, beam pointer mass, HPG mass, gunner's workstation mass, carriage mass (if any).

11C. Price

In MCr. Add tunnel price, beam pointer price, HPG price, gunner's workstation price, carriage price (if any).

11D. Power Requirements

In MW. Carry down from Step 8D above.

11E. Length

Actual tunnel length in meters. Carry down from Step 1 above.

11F. Surface Area

Surface area for a spinal mount is equal to the tunnel cross-sectional area times 2. Surface area for a bay-mounted PAW is equal to the bay's surface area.

11G. Combat Performance

Short range, medium range, long range, and extreme range in km and/or space combat hexes, plus damage values at those ranges, along with ROF, listing any –difficulty modifiers as applicable. Carry down from Steps 7 and 8C.

CHAPTER 6
Meson Guns

Meson guns are an extremely advanced form of particle accelerator that becomes available at TL 11. Like particle accelerators, the meson gun accelerates charged subatomic particles to very high velocities, but unlike simple particle accelerators, the meson gun does not simply fire these particles at enemy targets. Instead, the high-velocity particles are made to collide, creating in the process another particle, a meson (mesons are the subatomic particles that transmit the strong nuclear force within the atomic nucleus). By carefully aiming the colliding particles, the direction and velocity of the resulting mesons can be controlled.

Mesons do not interact with matter, and therefore follow a perfectly straight path, passing through all obstacles. However, the meson has a very short life span, and soon explosively decays, producing radiation and damaging particles. By accelerating a meson to relativistic speeds, its subjective passage of time is slowed, and its decay is delayed. By controlling the precise velocity of a meson, its decay can therefore be timed to take place at a certain distance, ideally inside an enemy ship, whose armor is completely useless.

Because of the need to accelerate the primary particles that produce the meson, and to control their speed and trajectory so that the mesons are emitted in the proper direction and at the correct velocity, a meson gun must be extremely long and straight in order to be most effective.

MESON GUN DESIGN

1. MESON TUNNEL LENGTH

Tunnel length aboard ship is defined by the type of installation and the size of the ship the gun is to be fitted to. Ground-mounted meson guns can be built to any length desired, within normal cost, facility, and power constraints.

Spaceship installations are of three types: spinal, parallel, and bay.

1A. Spinal Mounts

As the name implies, a spinal mount meson gun serves as the central internal-strength member of the entire ship. The gun defines the longitudinal axis of the ship, as well as its axis of mass and thrust. The length of a spinal mount is equal to the length of the ship (in meters) as defined during the spacecraft hull design step. Spacecraft with an open frame hull form may not have a spinal mount.

The spinal mount can be installed to fire either dead ahead (this is the standard configuration) or dead astern (called the "stern chaser" configuration). Its arc of fire is therefore either 1 or 5 (see Spacecraft Design Evaluation, page 16).

Each ship may have only one spinal weapons mount. The one exception to this is the so-called "Janus" mount, in which two spinal guns are installed in the spinal tube butted against each other, one pointing forward and one astern, where each is half the total length of the ship.

1B. Parallel Mounts

Parallel mounts, like spinal mounts, are mounted directly fore and aft, parallel to the ship's spine. Unlike spinal mounts, there can be more than one per ship.

The length of a parallel mount is 0.8 times the length of the ship in meters. They may be installed to fire either directly forward into fire arc 1, or dead astern into fire arc 5.

Ships with a sphere hull form may make a slightly different use of parallel mounts. Rather than being restricted to mounting parallel mounts along the fore-and-aft axis, a sphere's dimension allows the installation of parallel mounts athwartships, firing broadside, or at any other angle off of the centerline. These mounts are designed just as normal parallel mounts, but may be installed to fire into any one arc of fire, not just 1 or 5.

1C. Bay Mounts

Meson guns may also be mounted in bays set into the hull surface. There is no limit to the number of meson gun bays that can be fitted to a ship, beyond the normal limits of hull surface area, mass, and volume.

A bay may be constructed to any size desired, although the most popular are the 50-ton (700 cubic meters) and 100-ton (1400 cubic meter) bays. A bay's dimensions are calculated as follows.

Each bay has a single long dimension and two shorter dimensions. The long dimension, in meters, is found by taking the bay's volume in cubic meters, extracting the cube root, multiplying by 1.4, and rounding to the nearest whole number.

$$1.4\sqrt[3]{\text{Vol}}$$

Divide the bay's total volume in cubic meters by the long dimension, and extract the square root of this result, rounding to the nearest 0.5 meters. This is the approximate length of the bay's short dimensions. Multiply the long dimension by the short dimension to get the surface area of the bay in square meters.

Standard Bays and their Dimensions

Size	*Cubic Meters*	*Long Dim.*	*Short Dim.*	*Surface Area*
50 ton	700	12 m	7.5 m	91.2 m²
100 ton	1400	16 m	9.5 m	150.4 m²

The length of the meson gun tunnel is the long dimension of the bay.

2. DISCHARGE ENERGY

Specify the amount of output energy that will be fired in each shot (*discharge energy*, abbreviated DE) in megajoules (Mj). The greater the discharge energy, the greater the damage of each shot, and the greater the final size of the meson gun.

There is no inherent limit to the amount of discharge power, other than power supply requirements, size of ship, etc.

3. MESON TUNNEL CHARACTERISTICS

Find effective tunnel length, tunnel volume, tunnel mass, and tunnel price based on tunnel length in meters, discharge energy, and the table below.

MESON TUNNEL CHARACTERISTICS

TL	*Length Multiplier*	*Vol Multiplier*	*Mass Multiplier*
11	0.8	0.02	1.0
12	1.0	0.01	0.75
14	1.2	0.01	0.6
16	1.4	0.005	0.5
18	1.5	0.005	0.4
20	1.6	0.002	0.3
22	1.8	0.002	0.2
24	2.0	0.001	0.1

3A. Tunnel Effective Length

The effective length (meters) of the tunnel used in calculating range performance below

Effective Length = actual tunnel length (meters) × length multiplier

3B. Tunnel Volume

Tunnel Volume (cubic meters) = actual length (meters) × discharge energy × volume multiplier

3C. Tunnel Cross-Sectional Area

Cross-sectional area in square meters is equal to tunnel volume divided by actual tunnel length.

3D. Tunnel Mass

Tunnel Mass (tonnes) = tunnel volume (cubic meters) × mass multiplier

3E. Tunnel Price

Tunnel Price (MCr) = tunnel volume (cubic meters) × 0.1 at all tech levels

4. PERFORMANCE

The effective range (range at which energy delivered on target is equal to discharge energy) in kilometers is equal to the meson gun's effective tunnel length × 1000. Beyond this range, the beam's power drops due to dissipation of intensity and uncontrolled meson decay.

To find space combat range in hexes/range bands, divide this result by 30,000.

5. DEFINE SHORT RANGE

Select a beam pointer from the Beam Pointer table in the Fire Control chapter (Section 14) based on the gun's tech level and the range performance desired. Note that range is given in kilometers and 30,000-km hexes/range bands for space combat. The listed range in km/hexes will be the gun's short range for purposes of combat. Whenever possible, the beam pointer range should be equal to the gun's effective range to take full advantage of the gun's range-intensity performance.

6. COMBAT RATINGS

6A. Combat Range Bands

All combat ranges are based on the gun's short range.

Medium range = Short range × 2

Long range = Short range × 4

Extreme range = Short range × 8

Note: Meson guns have a maximum range in thousands of kilometers of 8.5 times their effective tunnel length. If a meson gun's short range is selected in such a way that its extreme range is in excess of this maximum figure, the gun has no extreme range band, and is unable to fire at any targets beyond its long range.

6B. Damage Value

Define the particle accelerator's damage characteristics at its short, medium, long, and extreme range bands.

Meson guns do damage to enemy targets based on their *damage value* (DV).

$$DV = 5\sqrt{I}$$

where I is the weapon's *intensity* at that range. Intensity is derived by the formula

$$I = DE \div (R+EL)^2$$

where

DE is discharge energy from Step 2 above

R is range (short, medium, long, or extreme, as defined in 7A above) in 1000s of kilometers

EL is the effective length of the meson tunnel from Step 3A above

Note that the term $(R+EL)^2$ should be rounded to the nearest 0.5 (e.g., 1.24 = 1, 1.25 = 1.5) before dividing DE, with a minimum result of 1.

Calculate DV for short, medium, long, and extreme range. The short range in hexes for space combat meson guns will often fall between two whole number values. Designers should try calculating intensity for both these hexes before selecting the beam pointer, above, because if $(R+EL)^2$ for the farther hex is between 1 and 1.24, effective range will round up to that hex. Note that this rounding may result in the loss of the extreme range band. Compare the longer short range in hexes × 8 to (effective length × 8.5) ÷ 30 to see if this is the case.

7. POWER REQUIREMENTS

7A. Input Energy

Meson guns have a 20% energy efficiency, meaning that of the energy put into each shot, 20% is projected toward the enemy in the form of mesons as discharge energy. The remaining 80% is spent creating, accelerating, and magnetically aiming the subatomic particles.

Find input energy in Mj according to this formula:

Input Energy (IE) = Discharge Energy (DE) ÷ 0.2

7B. Homopolar Generator

A meson gun requires a homopolar generator (HPG) to store the energy required for each shot until that energy is ready to be expended as a single pulse. The HPG's volume is calculated by multiplying the gun's input energy (IE) in Mj determined above by the value on the HPG table in the Power Production chapter (Section 8).

7C. Rate of Fire

Select the meson gun's rate of fire (ROF).

Space Combat: Any meson gun intended to be used for space combat must have an ROF of at least 10 shots per 30-minute space combat turn. Higher rates gain the gun reductions in difficulty level according to the table below. Due to the tremendous energies generated by each shot, which must be dissipated during the cooling purge cycle, the maximum ROF of a meson gun is 100 shots per 30-minute turn.

Diff Mods on the following table apply to space combat only, not ground combat.

RATE OF FIRE BENEFITS IN SPACE COMBAT

Space Combat ROF (Shots per 30-minute turn)	*Benefit (In Difficulty Modifiers to Fire Task)*	*Ground Combat ROF (Shots per 5-second turn)*
10	None	1/36
50*	–1 Difficulty levels	1/8
100*	–2 Difficulty levels	1/4

*There is no penalty for firing a meson gun at one of these higher power levels if it is mounted in a vehicle or starship which is designed from the outset to provide sufficient power for the higher ROF (50 or 100 shots). Nonetheless, meson guns which were not installed with the higher power levels may fire at these levels if sufficient power is made available by diverting it from other systems. However, because of the extra strain this places on power couplings, HPGs, etc., an Engineering task must be rolled each turn this is attempted (roll using crew quality). The difficulty level is Difficult if the ROF is raised one step (from 10 to 50 or from 50 to 100) over the installed power allocation, or Formidable if raised two steps (10 to 100). Failure at this roll indicates a System Reset result (see the **TNE** Space Combat chapter, or **Brilliant Lances: Traveller Starship Combat**), with the additional penalty that the meson gun may not fire on the current turn. Catastrophic Failure indicates more severe damage. Roll 1D10: 1-5 indicates a Degraded Performance result in addition to System Reset, 6-10 indicates a Major Hit on the meson gun.

Planetary Combat: To convert space to planetary ROFs, divide the space combat ROF per 30 minutes by 360. Take the inverse (i.e., divide 1 by that number), and round fractions *up*. The result is the number of five-second combat turns required for each shot. Express this number as a fraction, i.e., one shot every five turns is 1/5, one shot every 36 turns is 1/36, etc. Because this conversion system results in distortion of total number of shots due to rounding, this converted ROF must never be used when calculating power input. The original space combat ROF must always be used when rating a space combat meson gun.

ROF for planetary combat is defined in terms of five-second planetary combat turns. The maximum rate of fire for planetary combat is one shot every fourth turn (expressed as 1/4, due to the need for a cooling cycle following each shot.

7D. Power Input

Power input in megawatts (MW) is calculated differently for space combat and planetary combat meson guns. Although they are calculated differently, space and planetary combat power input values are absolute values, as they are both based on MW input per second. However, be careful to make these calculations based on the *true* ROF for each meson gun, based on its primary environment: space or planetary combat. Do not use ROFs converted from one system to the other, as the rounding involved distorts the numbers.

Space Combat Meson Guns: Multiply ROF per 30 minutes times input energy (IE) from Step 7A. This is the total number of megajoules needed over the course of a 30-minute turn. Divide this result by 1800 to find the MW of power that must be allocated to operate the weapon.

Planetary Combat Meson Guns: Multiply ROF times input energy (IE) from Step 7A. This is the total number of megajoules consumed by the weapon each five-second turn. Divide this result by 5 to find the MW of power that must be allocated to operate the weapon.

8. GUN CREW AND WORKSTATIONS

All meson guns must be crewed according to the following formula:

Crew = (Tunnel Volume ÷ 100) × CP

CP: Computer multiplier based on tech level of computer installed aboard ship/linked to ground-based PAW. See Computers table in the Controls chapter (Section 4).

Round to the nearest whole number, but results of less than 1 must always be rounded up to 1.

Each crewmember must have a gunner's (normal) workstation installed with characteristics obtained from the Controls chapter (Section 4).

9. MESON GUN CARRIAGE, MOUNT, ETC.

If the gun is to be mounted in a starship, skip this step. If the gun is intended for use as a towed weapon, calculate the size of its carriage, mount, etc. A towed carriage has the same mass as the meson gun mounted on it.

The gun must include its HPG, but may be plugged in to a power source at its destination. Carriage-mounted meson guns have an all-around armor value of 1. This can be increased by enclosing the gun and its supporting equipment in a "hull" (cylinder hull form) with a certain thickness of armor according to the vehicle or spacecraft design rules. As this armor increases the mass of the gun, it will increase the mass of the carriage as well.

The price of the carriage, in MCr, is equal to its mass in tonnes multiplied by 0.002.

For use in planetary combat, meson guns make excellent indirect fire weapons. Although a meson gun is actually a pure line-of-sight weapon, the fact that it can fire through intervening forests, mountains, even entire planets (if it has sufficient range) means that its fire control solutions are usually of an indirect nature. Meson guns are hardly ever risked in the direct fire role, as they are too valuable.

Ground combat (vehicle- or carriage-mounted) meson guns are usually equipped with indirect fire control systems. Performance details, weight, volume, and price are in the Fire Control chapter (Section 14).

10. MESON GUN PHYSICAL CHARACTERISTICS

Add up or bring down the above components to obtain the following total figures for the gun.

10A. Volume

In cubic meters. Add tunnel volume, beam pointer volume, HPG volume, gunner's workstation volume, carriage volume (if any), indirect fire controls (if any).

10B. Mass

In tonnes. Add tunnel mass, beam pointer mass, HPG mass, gunner's workstation mass, carriage mass (if any), indirect fire controls (if any).

10C. Price

In MCr. Add tunnel price, beam pointer price, HPG price, gunner's workstation price, carriage price (if any), indirect fire controls (if any).

10D. Power Requirements

In MW. Carry down from Step 7D above.

10E. Length

Actual tunnel length in meters. Carry down from Step 1 above.

10F. Surface Area

Surface area for a spinal mount is equal to the tunnel cross-sectional area times 2. Surface area for a bay-mounted gun is equal to the bay's surface area.

10G. Combat Performance

Short range, medium range, long range, and extreme range in km and/or space combat hexes, plus damage values at those ranges, along with ROF, listing any –difficulty modifiers as applicable. Carry down from Steps 6 and 7C.

11. DEEP SITE MOUNT

Because they can freely fire through matter, meson guns buried in "deep sites" far beneath a planetary surface are favored planetary defense weapons. Not only are they immune to fire except from other meson guns, their location can be difficult to determine. During the Final War, the crews of deep meson gun sites were the last living persons on some worlds.

11A. Volume

Volume of the deep site is a sphere calculated from the length of the meson gun.

Divide gun length by 2 to get radius of the sphere in meters.

$^4/_3\pi r^3$ = volume of sphere

Mass of this sphere is irrelevant, as it is immobile. Price is equal to tunneling costs per cubic meter, below.

11B. Lift Carriage

The gun has infinite traverse within its sphere. This is provided by a lift carriage which negates the various bending stresses on the tunnel so that it retains its accuracy, and also allows it to be traversed.

Install a CG lifter from the Lifters subsystem chapter (Section 10) based on the volume of the sphere. Volume of the generator is added to that of the sphere. Mass is irrelevant, and price is calculated normally.

If contra-grav technology is not available, the gun must have a mechanical carriage which costs MCr0.01 per cubic meter of sphere.

11C. Other Support Systems

Fire control, crew, and power requirements are determined the same as for any other meson gun. In addition, crew for the power plant plus life support, staterooms, etc. should be provided. Costs for all of these elements are calculated normally.

Access to the surface is provided by twin high-speed elevators. Volume of this shaft equals the depth of the site beneath the surface times a cross section of 36 square meters. Cost is MCr0.001 per vertical meter of shaft.

Once all components of the deep site have been calculated, total their volume (including the access shaft) to calculate the cost of tunneling based on the table below.

TL	*MCr/cubic meter*
7	0.0005
8	0.0003
9	0.0002
10	0.00015
11	0.00015
12	0.00007
13	0.00007
14	0.00007
15	0.00007

CHAPTER 7
High-Energy Weapons

High-energy weapons use a laser to heat hydrogen to a plasma state, containing it in a magnetic bottle until it reaches maximum energy, then opening an aperture in the bottle, releasing the plasma in a high-temperature, high-velocity (in excess of 8000 meters per second) jet. Fusion weapons operate on identical principles but contain the plasma slightly longer until a fusion reaction begins.

High-energy weapons use power cartridges identical to those used in explosive power generators as their ammunition. Each high-temperature ceramic cartridge is ignited and serves as the liner for the magnetic bottle that contains the plasma generated inside it. Recoil energy activates a purge cycle, during which liquid nitrogen is used to cool the cartridge before a new one is fed into the chamber from the magazine or autoloader, kicking what's left of the spent one out of the weapon (some of the mass of the cartridge becomes a part of the plasma jet). After the purge/eject cycle, the action locks closed, and the weapon is ready to fire again. The spent cartridge case is still hot enough to inflict burns on unprotected skin, although the purge cycle cools it enough so that it is no longer a source of ignition.

The heat of the ejected cartridges and the incidental heat from the plasma stream require users to wear protective clothing of some sort. The flame-retardant properties of most standard military uniforms provide adequate protection.

Supporting hardware consists of the cooling system and the power pack for the magnetic bottle. In the case of small arms weapons, this supporting hardware is worn as a backpack and the plasma or fusion cartridges are loaded into the weapon in detachable box magazines.

ENERGY WEAPON DESIGN SEQUENCE

A. Specifications

The characteristics of high-energy weapons are determined by five specifications. In addition, the weapon's power cartridge is designed at this time, as it is used through the rest of the design sequence.

1. Tech Level: Determine the tech level of design of the weapon. Plasma weapons can be designed from tech level 10 and up. Fusion weapons can be designed from tech level 14 and up.

2. Pulse Energy: Pulse energy is measured in megajoules (Mj) and is the basic defining parameter of energy weapon performance. Theoretically, any pulse energy level may be specified, but there are practical limits based on the size of weapon desired.

3. Fire Control: The type of fire control equipment, if any, must be specified. Since energy weapons are direct line-of-sight weapons, they do not require sophisticated rangefinders. A simple optic sight is sufficient for most targets, and this is included in the basic cost of the weapon. Ballistic computers or point-defense computers may be added to give the weapon a better capability against high-speed targets. Enhanced-visibility equipment may be added to enable the gunner to engage targets in limited-visibility conditions. See Fire Control, Section 14.

4. Mount: An energy weapon may be hand-carried or mounted either on a carriage or directly on a vehicle. All guns mounted on vehicles and on towed carriages are collectively called "cradle guns," as opposed to smaller man-portable weapons, which are usually called rifles, or in militarese, PGMPs (plasma gun, man portable) and FGMPs (fusion gun, man portable).

5. Options: A cradle gun may have a gun shield if desired, which provides the crew some protection against fragmentation and small arms fire from the front. If vehicle-mounted the gun may also have an autoloader.

6. Power Cartridge: Ammunition for energy weapons consists of explosive power generation (EPG) cartridges, which provide both power for the system and the fuel mass that forms the plasma stream fired by the weapon. At tech level 10, these are CPCs, at TL 12 they are PPCs, at TL 14 PFCs, and at TL 16 GCFCs, as described in the explosive power generation section of the Power Production chapter (Section 8).

Consult the Power Production chapter and design a cartridge from the correct tech level which has the output necessary to power the weapon.

B. Mass

The complete weapon system weight is equal to the weight of the weapon itself, plus its supporting hardware, plus its fire control equipment, plus its recoil system, plus its gunshield (if any), plus its feed system. The empty weight of a small arm energy weapon is equal to the mass of the firing unit. The loaded mass of a small arm energy weapon is equal to the mass of the firing unit plus the mass of a loaded magazine.

1. Firing Unit: The firing unit consists of what we would call the barrel and receiver of a conventional small arm. The ammunition supply feeds plasma or fusion pulse cartridges into the receiver where the internal ignition lasers of the system heat the fuel in the cartridge to a plasma state. The firing unit also contains the pilot laser that opens the atmospheric tunnel for the passage of the plasma or fusion bolt.

The mass of the firing unit is determined by the following formula:

Mf = TmPp

Mf: Mass of the firing unit in kilograms
Pp: Pulse power in megajoules
Tm: Tech level multiplier, as shown on the following chart:

TL	*Tm*
10	8
11	6
12-14	4
15	2
16-17	1
18-19	0.5
20+	0.3

2. Supporting Hardware: The supporting hardware includes the liquid nitrogen (LN) purge cooling system and a power pack to support the magnetic bottle. The power pack includes a small battery and homopolar generator (for the pilot laser) and is thermoelectrically powered by excess heat from the main ammunition ignition system. On man-portable weapons, the supporting hardware is contained in a backpack linked to the weapon by a multiflex cable including data, power, and LN lines.

The mass of the firing unit is determined by the following formula:

Ms = TmPp

Ms: Mass of the supporting hardware in kilograms
Pp: Pulse power in megajoules
Tm: Tech level multiplier, as shown on the following chart

TL	Tm
10	12
11	10
12	8
13	6
14	4
15	2
16-17	1
18-19	0.5
20	0.3

3. Fire Control: The weights of the various fire control systems are given in the Fire Control chapter (Section 14). Basic optic sights are included in the mass of the firing unit.

4. Recoil System Weight: Man-portable energy weapons do not require a cradle. The mass (and price) of a stock are subsumed in the basic cost of the firing unit.

At tech level 10, gyroscopic recoil compensators become available. This recoil compensator is a gyroscopic unit mounted in a backpack and body harness to which the gun is connected by a flexible articulated arm. The arm becomes rigid when the weapon is fired and helps absorb the recoil.

At tech level 14 and beyond, inertial compensators become available to reduce the recoil of man-portable energy weapons. This is a more sophisticated version of the gyro-compensator.

The mass of both gyroscopic and inertial compensator is determined by the following formula:

Mc = TmPp

Mc: Mass of the compensator in kilograms.

Pp: Pulse power in megajoules.

Tm: Tech level multiplier, as shown on the following chart:

TL	Tm
10-11	6
12-13	5
14	4
15	2
16-17	1
18-19	0.5
20	0.3

Cradle guns, whether they are towed or vehicle mounted, require a recoil-absorbing cradle. This is similar in design to the hydraulic recuperators used to absorb recoil on CPR guns.

The mass of the recoil cradle is determined by the following formula:

Mr = TmPp

Mr: Mass of the recoil cradle in kilograms

Pp: Pulse power in megajoules

Tm: Tech level multiplier, as shown on the following chart

TL	Tm
10	75
11	50
12	35
13-14	20
15-16	15
17-18	10
19-20	6
21+	4

Towed guns also require a carriage. The carriage weight of a gun, in tonnes, is its muzzle energy in megajoules divided by 2.

Vehicle-mounted cradle guns do not require carriages, but the vehicle itself must weigh at least twice the required carriage weight.

5. Gun Shield: The weight of a gun shield in tonnes is equal to 0.1 times the pulse energy in megajoules.

6. Feed System: Specify the number of cartridges in the magazine. On cradle guns or very large man-portable weapons, this will usually be only one, with individual rounds loaded by hand or by autoloader into the weapon each time it fires. For most man-portable weapons, several rounds can be carried in a box magazine attached to the weapon.

The mass of a box magazine is determined by the following formula:

Wm = .6(N+4)Wa

Wm: Weight (in kilograms) of an empty magazine.

Wa: Weight (in kilograms) of a complete round of ammunition.

N: Number of rounds the magazine is designed to hold.

A loaded magazine weighs this plus the weight of the individual cartridges loaded into it.

The weight of the auto-loader is equal to the cartridge weight times 30.

C. Gun Crew

The number of crewmen required to man a gun depends on its function and how it is mounted. A crew normally consists of a gunner and several loaders.

The crew required to serve a towed (carriage-mounted) energy weapon is equal to the mass in kilograms of its power cartridge multiplied by 0.03, rounding fractions up. Vehicle-mounted weapons require a crew half this size, rounding fractions up, but never less than two. Vehicle-mounted weapons equipped with autoloaders require a crew of only one (the gunner).

D. Range

Weapons have four direct fire ranges: short, medium, long, and extreme. Medium range is 2 × short, long is 4 × short, and extreme is 8 × short.

Direct fire range is mostly a function of the pulse energy of the weapon. A second consideration is the type of weapon, as fusion guns have a longer range for the same energy than do plasma guns.

Short direct fire range in meters for a plasma gun is its pulse energy in megajoules multiplied by 30.

Short direct fire range in meters for a fusion gun is its pulse energy in megajoules multiplied by 50.

E. Damage Value

The damage value of an energy weapon at short range is calculated using the following formula:

D = 11.5(√P)

D: Damage value

P: Pulse power in megajoules

F. Penetration

Penetration is expressed in two ways: as *penetration value*, and as *penetration rating*.

Penetration value is a measure of the weapon's absolute ability to penetrate armor, and is the measure most often used in vehicle combat.

Penetration rating describes the relationship between the weapon's damage value and its penetration value. Penetration value = Damage value + Penetration rating. Likewise, Damage value = Penetration value × Penetration rating.

Penetration rating is also equal to the number of points of damage value that are lost for each level of armor value that is penetrated (thus the smaller the penetration rating, the better the penetration performance). This is the measure most often used in personnel combat. Penetration ratings become higher (i.e., penetration performance becomes worse) as range increases. Ratings are given by range: short/medium-long-extreme (penetration rating for medium is the same as for short).

Plasma weapons have a penetration rating of 1-2-10.

Fusion weapons have a penetration rating of ½-1-4.

Small arms are usually listed with their damage value and penetration ratings listed separately.

Cradle guns are usually listed with their damage value and penetration ratings combined into their penetration values at the various ranges.

Thus, a small arms fusion gun might be described as having a damage value of 20 with penetration ratings of ½-1-4. That same fusion gun, if it were rated as a cradle gun, would have listed penetration values of 40-20-5 (short/medium-long-extreme).

G. Reloading

The time the weapon requires to reload is a function of its power. The base number of five-second turns required to load a round is equal to its pulse power (in megajoules) divided by 3, rounding fractions to the nearest whole number. A result of less than 0.5 (which rounds down to 0) indicates that a round can be reloaded in the same combat turn in which the weapon fires, leaving it capable of firing again in the next combat turn.

If an autoloader is available, multiply power cartridge weight by 0.3 for purposes of this calculation.

If the weapon is man-portable and fed by a box magazine, the weapon is always semiautomatic with a maximum rate of fire of 1 round per combat turn.

H. Price

The price of the weapon is equal to the price of its components. Fire control equipment costs are listed in the Fire Control chapter (Section 14). The prices (in credits) of other components are determined by their mass (in kilograms)and cost multipliers, as shown below. Note that the cost multipliers for certain components of plasma and fusion guns are different.

Price Multiplier

Component	*Plasma*	*Fusion*
Firing Unit	2500*	7500*
Support Hardware	2500*	7500*
Gyro-Compensator*	1000	1000
Inertial Compensator*	2500	2500
Recoil Cradle	100	100
Towing Carriage	2	2
Autoloader	10	10
Gun Shield	1	1

• Installing a gyro-compensator or inertial compensator requires that the electronic components of the system be designed more robustly. This has no effect on mass, but doubles the price of the firing unit and support hardware.

Empty magazines cost Cr1 per kilogram, rounding fractions up.

I. Set-Up

A towed energy weapon must be set up before it can fire. The set-up time (in five-second combat turns) for a towed energy weapon is determined by multiplying the total mass of the weapon (in tonnes) by 10.

J. Volume

The volume of an energy weapon in cubic meters, for purposes of transportation or mounting in a vehicle, is equal to the mass of its components in metric tonnes multiplied by 0.5 (for the firing frame and support hardware) or 1 (for all other systems).

K. Recoil

Recoil is only calculated for man-portable weapons, not cradle guns. Recoil is calculated using the following formula:

$$R = \{[(150\sqrt{E})+Ww]Rcm\}$$

R: Recoil number

E: Pulse energy in megajoules

Ww: Weight, in kilograms, of weapon (loaded)

Rcm: Recoil compensator modifier. The only allowed recoil modifiers are from gyroscopic or inertial compensators. (All plasma and fusion weapons are assumed to have recoil-absorbing stocks as standard equipment. Muzzle brakes are not effective, and in fact are extremely dangerous, on energy weapons.) The recoil modifiers for these vary with tech level and are shown below. Note that these systems, due to the larger recoil forces at work, are not as effective at reducing recoil as similar systems used with small arms.

TL	*Type*	*Rcm*
10	Gyro	.8
14	Inertial	.5
15	Inertial	.4
16	Inertial	.3
18+	Inertial	.2

L. Bulk

Bulk is only calculated for man-portable systems, not cradle guns. Bulk is calculated using the following formula. However, results of greater than 5 are treated as 5.

$$B = MfTm$$

B: Bulk

Mf: Loaded mass (in kilograms) of the firing unit.

Tm: Tech level modifier, as shown below.

TL	*Tm*
10-11	3
12	2
13	1.5
14	1.25
15	1
16+	0.75

CHAPTER 8
Lasers

Laser, as all science-fiction gamers probably know, stands for Light Amplification by the Stimulated Emission of Radition, and is one of the most used—and, it would appear, misused—concepts in science-fiction gaming. (Incidentally, lasers were originally referred to as "optical masers"—maser = Microwave Amplification by the Stimulated Emission of Radiation—although masers could as easily be referred to as "radar lasers.")

Laser Basics

The key concept behind lasers is *stimulated emission*, meaning that an atom or molecule is hit by light of a particular wavelength which then causes that particle to emit light of that same wavelength. The reason that substances can be stimulated to produce specific wavelengths has to do with the way atoms and molecules store and release energy with their electrons. Electrons belonging to an atom are found in "orbits" (they are not really orbits, but in the interest of not going into weird existential Schrödinger's cat-style quantum physics, orbits are a close enough concept) around the atom's nucleus (that's *noo-klee-us*, Mr. Secretary). These electrons move from low-energy orbits close to the nucleus out to high-energy orbits farther from the nucleus as they gain energy by absorbing photons, and move back in toward the nucleus as they give up energy by emitting photons.

These orbits are not set up with an infinite number of fine gradations, they are more like the rungs of a ladder—there are only so many, and they are a fixed distance apart. One can step up or down one, two, three or more rungs at a time, but cannot go up or down a fraction of a rung. Like the difference between electron orbits, the differences between the rungs on a ladder are *quantized*. This means that an electron which absorbs a photon and moves, or *transitions*, to a higher orbit, or *energy level*, can only have absorbed a photon with a certain fixed amount of energy, no more and no less, to move to that energy level. As that same electron transitions back down to the earlier lower energy level, it emits that same amount of energy, the difference between the two energy levels, in the form of a photon which is identical to the photon it absorbed earlier. Thus, based on the number of available energy levels and the combination of transitions (energy level 0-1, 0-2, 0-3, 1-2, 1-3, etc.), an atom can only absorb or emit photons of certain discrete energies.

Photons are described in three ways: by their energy, their frequency, and their wavelength (remember that electromagnetic radiation behaves as simultaneously as particles—photons—and waves, so that particles can be said to have frequency and wavelength). However, these are merely three different descriptions of the same thing—a given wavelength is equivalent to a certain frequency is equivalent to a certain energy. That means that an atom which can only absorb or emit photons of certain energies can only absorb or emit radiation of a certain wavelength.

Molecules also store energy electronically as just described, but they also store energy as vibrational energy, where the component atoms vibrate back and forth with relation to each other, and rotational energy, where the molecule rotates around its center of mass (atomic nuclei cannot store energy like this because their mass is completely symmetrical). However, like electronic energy, vibrational and rotational energy are also quantized—there are only certain allowed levels of these energies, which of course define the energy/wavelength of the photons that these molecules can absorb or emit. (Rotational transitions are the least energetic, with most transitions corresponding to the far infrared portion of the spectrum. Most vibrational transitions are in the near infrared. Electronic transitions are the most energetic, with most of these corresponding to the visible and ultraviolet portion of the spectrum. However, there are notable exceptions to all of these generalizations. Nonetheless, this means that electronic transformations are the most useful for military purposes, as we will see below.)

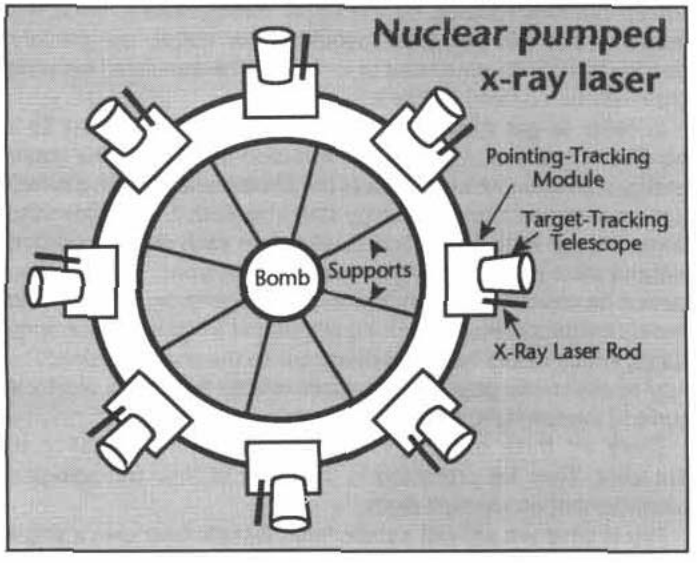
Most photon emission is spontaneous. Energetic atoms or molecules, like those in the filament of a light bulb, shed their energy by spontaneously spewing photons—atoms and molecules tend to be in their lowest energy states, so the chances of spontaneous emission increase with the energy state. What stimulated emission does is to hit an energetic atom or molecule with a photon of a wavelength that corresponds to one of that atom or molecule's transitions (i.e., a wavelength which it can absorb or emit). If the atom or molecule is already at the energy state where it can emit a photon of the wavelength which struck it, the atom or molecule will emit that photon, and in the same direction as the photon which struck it, so that now there are two identical photons travelling in the same direction. So long as this takes place within a population of atoms or molecules which are already at the required energy level, this chain reaction will continue, creating ever more photons of the same wavelength. This is a laser. What? No powerful concentrated beam? Nope. All that is required of a laser is laser gain—the amplification of light radiation by stimulated emission—it need not be unidirectional, or focussed. Mars' upper atmosphere is one such non-unidirectional laser. If this emission takes place between a pair of focusing mirrors, the photons will bounce back and forth, continuously stimulating more photons travelling in the same direction, until one of the mirrors is made transparent ("Q-switched"), and the focused beam of photons is released. This is what we normally think of as a laser, although it is more properly a "diffraction limited laser." However, these diffraction limited lasers are what we simply call "lasers" in **Traveller** and in the design sequence below.

The problem is that a population of atoms or molecules will not all be at the proper energy state at the same time. Instead, they will naturally be at thermodynamic equilibrium, which means that the number of atoms or molecules at a given energy state varies inversely with the amount of energy in that energy state, with the result that each energy state is outnumbered by the lower energy state immediately beneath it (i.e., the energy state which will immediately absorb photons released by the upper energy states). What this means is that this population would rather absorb the photons coming by than be stimulated to emit any. The stimulated emission chain reaction is dead before it begins.

In order to get stimulated emission to work, there must be a *population inversion*. A population inversion means that the target energy state (that which produces the photon wavelength desired) is more common than the energy states beneath it. This allows the target energy state population to stimulate each other's emission without these photons being immediately absorbed. This inversion cannot be created simply by heating the population, as this would merely create thermodynamic equilibrium at a higher set of energy states, which would be just as disastrous to the chain reaction. The way to selectively populate an upper energy level is via electrical current, intense light, or chemical reaction.

There are three main types of lasers to discuss in relation to **Traveller**. They are presented in the order of their technological advancement on modern Earth.

First is what we will call a static laser. A static laser uses a single



population of atoms or molecules which are energized by electrical or light input, emit their photons and fall to a lower energy state, and are then re-energized to emit again, over and over and over. They are called static because they use the same population time after time. They are distinguished by the need for significant electrical input in order to function. Static lasers include modern ruby lasers, gas lasers, and excimer lasers. These are represented in **Traveller** by the direct electrical input lasers at the lower tech levels of roughly 7-9, with rubies and gas lasers from TL 7-8, and excimers from 8-9.

Second are chemical lasers. These lasers do not use the same population over and over, but continuously create a new energized population which emits its photons and is discarded. These atoms or molecules are not energized *per se*, but are created in an energized state as the products of an energetic chemical reaction. By keeping a continous reaction going and venting away the spent material, a population inversion can be maintained without the need for outside power input, as the energy comes purely from combusting chemicals. These are most commonly used in **Traveller** as small arms lasers.

Third are free-electron lasers, or FELs. This laser passes an electron beam through a series of magnets which bend the paths of the electrons. As the electrons' paths are bent, they are made to emit or absorb photons. By placing mirrors at both ends of the electron beam, the photons are gathered coherently to form a beam in the usual fashion. Because these electrons are free, and not bound to an atom, they are not locked into quantized energy states, and therefore can absorb or emit photons of any wavelength, depending upon how they are manipulated by the magnets. In this way, the FEL can actually be tuned to emit different wavelengths. In **Traveller**, FELs are represented by the great tunable direct electrical input lasers, the mainstay of **Traveller** space combat from TLs 10-15. For simplicity in the design sequence, however, these overlap with the static lasers above.

The non-tunable X-ray lasers that appear from TLs 13 to 19 are also FELs, but are very specialized to produce X rays and have therefore given up their tunability. X-ray stimulated emission is very hard to induce because the chance of inducing stimulated rather than spontaneous emission of a photon varies with its wavelength cubed. By the very short X-ray wavelengths, this probability has dropped off sharply from that of the more amenable, longer wavelengths.

An additional specialized type of laser should be mentioned. It is an odd subset of static laser, called the nuclear-pumped X-ray laser.

To create the necessary population inversion for X-ray emission requires a great deal of power, because the transition that produces an X ray is an extremely powerful one. The radiation from a nuclear explosion provides sufficient power, but also vaporizes the laser-producing population after one shot. Another troublesome characteristic of short wavelength stimulated emission is the incredibly short life time of their excited state before spontaneously emitting. In the case of the 10Å photon that would be emitted by a nuclear-pumped laser, this lifetime is only about 10^{-13} seconds (one-tenth of a trillionth of a second), which is probably just as well, under the circumstances.

The X rays are generated by a population shaped in the form of very thin rods, about a millionth of a meter in diameter. There are no mirrors or sophisticated focusing arrays on these expendable beam-generating rods. It is the shape of the rods themselves that create the beam by directing the path of the stimulated emission chain reaction along their lengths.

Laser Functions

All of the rules on laser performance and design are defined by the following formula which describes the physics of focusing light, based on its wavelength and its focusing elements.

$$I = (P+[(L+F)^2])+R^2$$

Where:

I= Delivered energy intensity (watts/cm²)
P = Discharge energy (watts)
L = Wavelength (centimeters)
F = Focal value (centimeters)
R = Range (centimeters)
L+F = Divergence angle (radians)

The calculations in the design sequence below do not require designers to use this formula, but all of the formulas and concepts are derived from it. One of the most important facts derived from this formula is that the shorter the wavelength of the laser, the better its range performance will be. The longer its wavelength, the worse it will be. Lasers start with rather long wavelengths (in the infrared band of the electromagnetic spectrum) at low tech levels, but are able to achieve shorter wavelengths at higher tech levels. The other important fact is that lasers, no matter how we might fervently wish it, do not have the range performance we have been led to expect by a steady diet of movies, television, and soft science fiction. Space combat ranges are simply too great.

All light disperses over distance, even diffraction-limited laser light. The variables are wavelength, diameter of the focusing elements, and range. We've already mentioned that short wavelengths are desired to get good range performance, and we know that the bigger the focal elements, the tighter the focus.

The problem is that dispersion increases with the *square* of the range. Once any variable becomes squared, it quickly overwhelms the other variables, particularly when the squared variable is big to begin with. In space, the range variable is very, very big. Very, very big squared is almost insurmountable.

To get an idea of how almost insurmountable real physics is, let's try a rough laser design using the formula above. How big does our focal array need to be? Let's try 10 meters in diameter, much larger than anything ever visualized for **Traveller**, or any other science-fiction game, movie, or TV show. And let's set its wavelength in the ultraviolet (UV) range, better than we can handle today, but not as good as X rays (which, as with earlier editions of **Traveller**, show up at TL 13), and we'll set its output at 1000 megajoules.

How does the beam hold together? At only 30,000 km (one space combat hex), its spot size is almost 70 meters in diameter, diluting the 1000 megajoules down to only 0.3 megajoules per square centimeter. Since a laser needs about 2 megajoules per square centimeter to punch through a centimeter of steel, our laser is off by a factor of almost 100 to punch a civilian starship hull, and that's at only one hex.

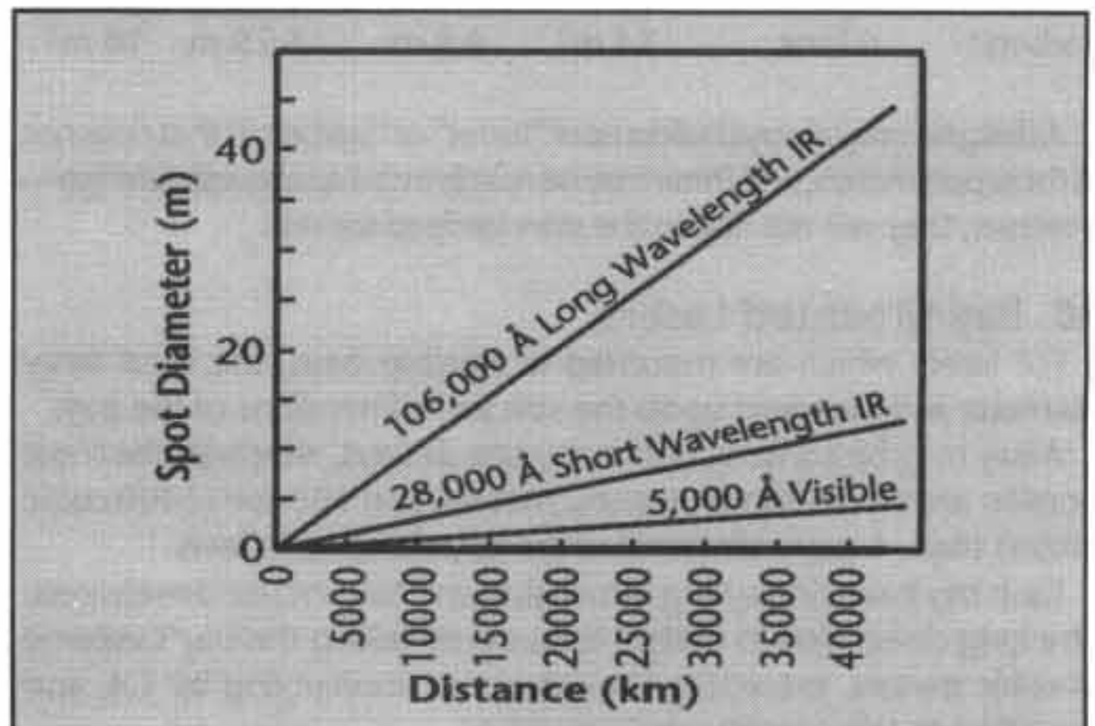
What do we need to get a 10-hex range with tight enough focus to punch a starship? We need a divergence angle of around 0.3 picoradians (10^{-12} radians), which we can get by using shorter wavelength light or a larger focal dish. But since we've already decided that UV is as short as we can go before TL 13, we're left with a dish diameter of *6000 meters*.

In order to deal with this cruel reality, **Traveller: The New Era** incorporates a rule for gravitic focusing to allow lasers to continue to have the long-range space performance we've all grown used to. This gravitic focusing of the laser beam appears at the same time as contra-gravity technology, and creates the effect of a larger diameter dish by creating an intense point source of gravity within the focusing area to bend the light with gravity. However, because this bending of light is such a departure, we present it as an optional technology, instead of just fudging the rules to cover up the reality gap. By doing this, we allow referees to design campaigns that use real physics, to discover what space combat of the future might actually be like, starting with SDI. Although we call it an optional technology, gravitic laser focusing is an official and important part of the Imperial Space campaign, and will be used in all **Traveller: The New Era** background material intended for that campaign.

LASER DESIGN

1. TECH LEVEL

The tech level at which a laser is built has obvious impact on its effectiveness. Tech level affects the mass and volume of the laser itself, its power supply, the wavelength of light that can be used, and the fire control systems that are used to guide it. Tech levels of 13 or greater also affect the type of laser that can be built. If the tech level is 13 or more, at this time the designer must designate if the laser will be a *tunable* laser or an *X-ray* laser.



Tunable lasers have a shortest allowable wavelength defined by their tech level. At most tech levels, this shortest wavelength is longer than X-ray wavelengths, and therefore cannot be focused as tightly and so has less range. However, a tunable laser can be tuned to fire a pulse of any wavelength equal to or longer than its shortest allowable wavelength, which is advantageous when firing into or through atmospheres. Ultraviolet and X-ray radiation are absorbed quite well by atmospheres, making these wavelengths quite useless for use in ground vehicles or for planetary bombardment from space. Even though visible and infrared wavelengths have poorer focusing and range performance than X rays, they are the only wavelengths useful for attacking targets within an atmosphere. Thus a tunable laser with a shortest allowable wavelength in the ultraviolet or soft X-ray bands could use these wavelengths for maximum range performance in space, but still be tuned to visible bands when conducting planetary bombardment.

X-ray lasers, on the other hand, are built for the maximum possible range performance in vacuum. But because of the specialized nature of equipment necessary to focus X rays, these X-ray lasers cannot be "de-tuned" to fire longer wavelength pulses. (Note, however, that at high tech levels, tunable lasers become capable of ever shorter wavelengths, so that tunable lasers and X-ray lasers eventually merge.)

2. GRAVITIC FOCUSING (OPTIONAL TECHNOLOGY FIELD)

Gravitic focusing allows lasers to be be focused at lethal intensities over the ranges at which **Traveller** space combat takes place. This is an official part of the standard Imperial Space campaign, but need not be used by players who are creating their own "universe" or campaign background.

Gravitic focusing does not require any additional equipment to be installed in the design sequence, but it does affect laser energy efficiency (Step 4), and adds another step to improve the performance of the laser in the performance rating step (Step 5).

Why Gravitic Focusing?

This graph shows the focussing performance of several current or hypothetical lasers using real-world physics. The graph shows the spot size at various ranges of a laser beam fired from a focal mirror 30 meters in diameter. Note that a range of 30,000 km is only one hex in **Traveller** space combat. Bearing in mind that intensities of at least one megajoule per square centimeter must be obtained to get meaningful combat performance, think of how hard that must be when a laser spot is over five meters across (50,000 square centimeters) at a range of only one hex.

This is why we have chosen in **Traveller: The New Era** to postulate gravitic focusing as an optional (though passionately recommended) technology field.

3. FOCAL ARRAY

Select the diameter of the laser *focal array* (abbreviated FA Diameter). At low tech levels, this is a pair of simple concave mirror at opposite ends of the laser-generating cavity. At higher tech levels, it is an array of smaller reflective surfaces which are focused mechanically or electro-hydraulically, using electricity or sound passed through a fluid focal medium to focus and traverse the beam. The larger the diameter of the focal array, the greater the range at which the laser beam can be focused to lethal intensities.

During the design sequence itself, the focal array diameter must be specified in meters, although small arms lasers are usually described in centimeters once their designs are completed. Many of the equations that follow require units in meters in order to give proper results.

In general, focal arrays may be built to any dimensions desired. However, certain standardized weapons installations are used on starships which require certain parameters to be observed.

3A. Standard Socket-Mounted Lasers

Most starships are fitted with one or more of two standard-sized *sockets*. These sockets will accept standard-sized lasers, missile launchers, and nuclear dampers. These sockets come in two sizes, referred to by tradition as turrets and barbettes. Turret sockets are 3 displacement tons (42 cubic meters), and barbette sockets are 6 displacement tons (84 cubic meters). Both sockets are cylinders, with the following dimensions:

Type	*Displacement*	*Volume*	*Diameter*	*Height*	*Surface Area*
Turret	3 tons	42 m^3	3.6 m	4.2 m	10 m^2
Barbette	6 tons	84 m^3	4.5 m	5.25 m	16 m^2

A designer may always build a laser "turret" or "barbette" that does not fit these parameters, and these may be readily installed aboard starships—however, they will not fit into the standardized sockets.

3B. Bay-Mounted Lasers

For lasers which are mounted in starship bays, the focal array diameter is dependent upon the size and dimensions of the bay.

A bay may be constructed to any size desired, although the most popular are the 50-ton (700 cubic meters) and 100-ton (1400 cubic meter) bays. A bay's dimensions are calculated as follows.

Each bay has a single long dimension and two shorter dimensions. The long dimension in meters is found by taking the bay's volume in cubic meters, extracting the cube root, multiplying by 1.4, and rounding to the nearest whole number.

$$1.4\ (\sqrt[3]{Vol})$$

Divide the bay's total volume in cubic meters by the long dimension, and extract the square root of this result, rounding to the nearest 0.5 meters. This is the approximate length of the bay's short dimensions. Multiply the long dimension by the short dimension to get the surface area of the bay in square meters.

Standard Bays and their Dimensions

Size	*Cubic Meters*	*Long Dim.*	*Short Dim.*	*Surface Area*
50 ton	700	12 m	7.5 m	91.2 m^2
100 ton	1400	16 m	9.5 m	150.4 m^2

The diameter of the focal array is equal to the short dimension of the bay.

Characteristics of the focal array are specified after selecting the laser's maximum pulse energy in Step 4.

4. DISCHARGE ENERGY

Specify the amount of output energy that will be fired in each laser pulse (*discharge energy*, abbreviated DE) in megajoules (Mj). Naturally, the greater the discharge energy, the more damaging the laser, and the more equipment is required to allow the laser to function.

Focal arrays fall into one of two performance brackets: *heavy* and *light*. A heavy focal array is any array, regardless of power output, which is intended for permanent installation in a vehicle, spacecraft, or static ground installation. A light focal array is one which is intended for use in a small arm or heavy weapon, and is generally man-portable. Light focal arrays (which can be more massive than a heavy focal array of the same power output) are therefore not subsumed under the various support systems (power, environmental protection, and cooling, etc.) of, say, a ship-mounted system, and require some additional expense as well as support components to be added separately (which will be detailed below).

A heavy focal array must be further defined as a trainable or fixed array. A trainable array is one which will be mounted so it can be traversed and pointed at its target, as in a turret or similar mount (this also includes barbettes, bays, and vehicle turrets). A fixed mount is one which will be mounted to have no flexibility, and must be aimed by pointing the vehicle in which it is mounted. This is typical of lasers mounted in the noses of fighters, fixed to fire directly ahead. When mounted in spacecraft in this way, these are referred to as laser "lances."

Now calculate the characteristics of the focal array. The volume of the focal array (in cubic meters) is its surface area (in square meters) times its maximum discharge energy (in Mj) times the tech level modifier from the table below.

Surface area is calculated by first dividing the FA diameter in meters by 2 to get its radius, r, in meters.

Surface area = πr^2, where $\pi = 3.1416$

Focal Array Volume Modifiers

	TL Modifier	
TL	*Heavy Focal Array*	*Light Focal Array*
7-8	1	10
9	0.1	1
10-11	0.01	1
12-15	0.001	0.5
16-19	0.0005	0.1
20+	0.0001	0.05

Mass: Mass in tonnes of the focal array is equal to its volume in cubic meters ×1

Price: Price in megacredits (MCr) of a trainable heavy focal array is equal to its volume in cubic meters ×0.2; of a fixed heavy array in MCr is cubic meters ×0.1, and of a light array in MCr is m^3 ×0.5.

Energy Efficiency and Input Energy: All lasers have a required amount of energy input, defined as input energy (IE) for each shot.

Non-Gravitic Focusing: Lasers designed without the gravitic focusing optional technology field derive their input energy from their energy efficiency based on tech level.

TL	*Efficiency*
7	0.20
8	0.25
9	0.30
10	0.35
11	0.45
12	0.55
13	0.65
14	0.75
15	0.85
16+	0.95

To find the input energy needed for each shot, divide DE in Mj by the efficiency value on the table according to tech level.

Gravitic Focusing: All lasers using gravitic focusing have a 20% energy efficiency. In other words, the discharge energy chosen above is only 20% of the total energy expended for each pulse; the remaining 80% is spent in generating the beam, generating the gravitic focusing elements, or lost as waste heat. To find the actual energy in Mj needed to fire each laser shot, use the equation

DE + 0.2 = input energy (IE) required per shot

5. LASER PERFORMANCE RATING

To find a laser's performance, multiply its *focal value* (F) by the range factor used at the laser's tech level. The result is the laser's *effective range* in kilometers. Effective range is the range at which the laser's full pulse energy is focused into an area on the target of 1 square centimeter. Within this range, a laser's full pulse energy is used to inflict damage on its target. Beyond this range, the beam's intensity per unit area diffuses, and the damage becomes lower. Effective range is not used in combat, but it is used in the steps below to derive the laser's combat performance at short, medium, long, and extreme range, which are used in combat.

5A. Non-Gravitic Focused

If the laser will not be using gravitic focusing, F is equal to the FA diameter in meters, and the range factor is selected according to tech level. Ignore the two columns (for X-ray lasers, single column) under the Gravitic Focusing heading.

5B. Using Gravitic Focusing

F must be calculated based on the gravitic focusing focal modifier. Based on the tech level and class of the focal array (heavy or light), choose the correct focal modifier. To apply this modifier:

1. Take the FA diameter (in meters) and convert it to decimeters (1 dm = 0.1 m) by multiplying by 10.
2. Apply the focal modifier to the diameter D in decimeters.
3. Divide the result by 10.
4. The result is the laser's focal value F. Multiply F by the proper range factor for the tech level to get the laser's effective range.

Note that for each focal modifier there is a lower limit of focal array size that can be gravitically focused. Because of the exponential function, beneath these levels the focal array effectiveness actually decreases. At $F = D^2$, for example, the lower limit is 0.1 meter.

TUNABLE LASERS

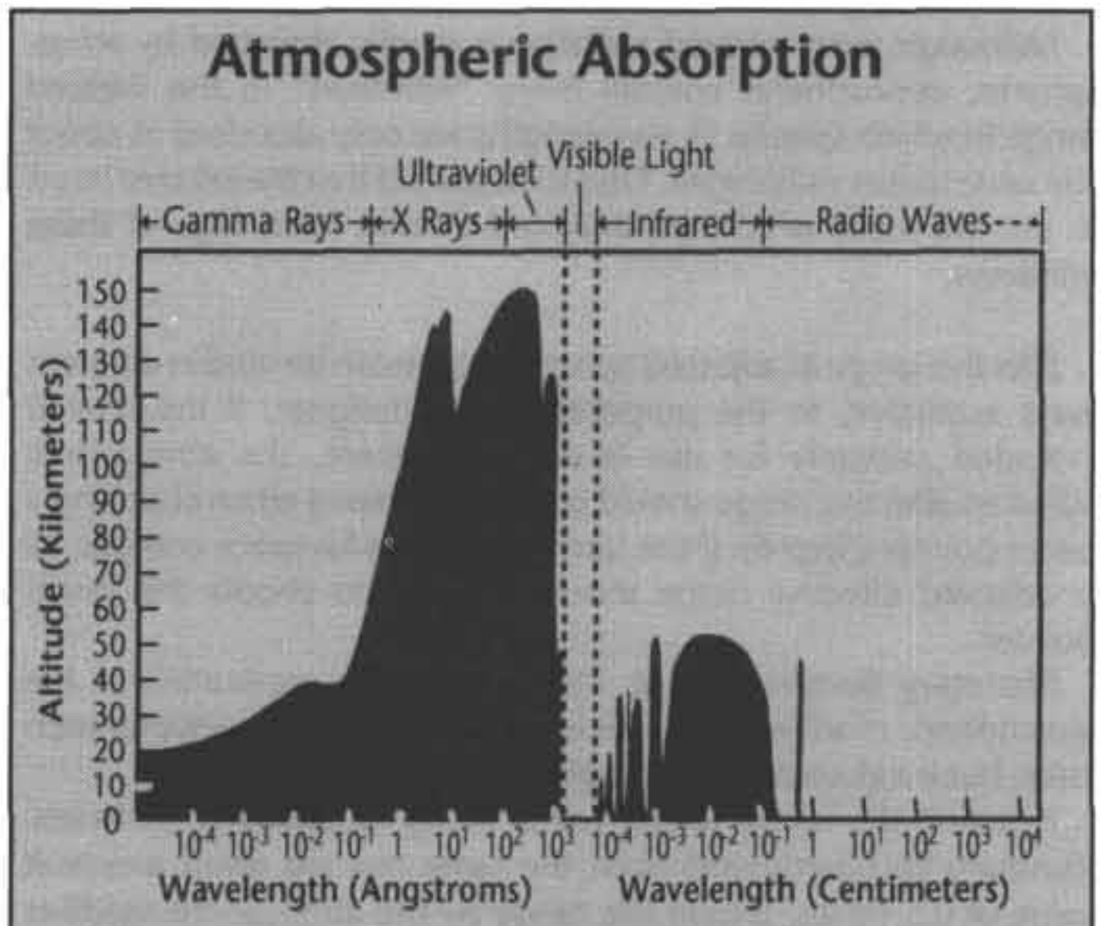
	Gravitic Focusing		
TL	*Focal Modifier (Heavy)*	*Focal Modifier (Light)*	*Range Factor (Wavelength of Light)*
7	$F = D$	$F = D$	3 (30,000 Å, Infrared: IR)
8	$F = D$	$F = D$	20 (5000 Å, Visible light: VL)
9	$F = D^2$	$F = D$	33 (3000 Å, Near Ultraviolet: NUV)
10	$F = (3D)^2$	$F = D^2$	50 (2000 Å, Ultraviolet: UV)
11	$F = (4D)^2$	$F = (3D)^2$	100 (1000 Å, Far Ultraviolet: FUV)
12	$F = (5D)^2$	$F = (4D)^2$	100 (1000 Å, Far Ultraviolet: FUV)
13	$F = (6D)^2$	$F = (5D)^2$	100 (1000 Å, Far Ultraviolet: FUV)
14	$F = (6D)^2$	$F = (6D)^2$	100 (1000 Å, Far Ultraviolet: FUV)
15	$F = (6D)^2$	$F = (6D)^2$	1000 (100 Å, Soft X-ray/Extreme UV: EUV)
16	$F = (6D)^2$	$F = (6D)^2$	2000 (50 Å, X-ray: XR)
17	$F = (6D)^2$	$F = (6D)^2$	5000 (20 Å, X-ray: XR)
18	$F = (6D)^2$	$F = (6D)^2$	10,000 (10 Å, X-ray: XR)
19	$F = (6D)^2$	$F = (6D)^2$	50,000 (2 Å, Far X-ray: FXR)
20	$F = (6D)^2$	$F = (6D)^2$	100,000 (1 Å, Extreme X-ray: EXR)
21	$F = (6D)^2$	$F = (6D)^2$	200,000 (0.5 Å, Near Gamma ray: NGR)
22	$F = (6D)^2$	$F = (6D)^2$	500,000 (0.2 Å, Gamma ray: GR)
23	$F = (6D)^2$	$F = (6D)^2$	1,000,000 (0.1 Å, Gamma ray: GR)

Notes:

At TL14+, the distinction between heavy and light focal arrays no longer affects focusing performance.

At TL 20+, the distinction between tunable and X-ray lasers becomes irrelevant, as lasers are now tunable down to X-ray wavelengths.

X-Ray Lasers



For heavy focal arrays only. Light focal arrays must use tunable table above.

TL	*Heavy Focal Modifier*	*Range Factor (Wavelength of Light)*
13	$F = (4D)^2$	100,000 (1 Å, Extreme X-ray: EXR)
14	$F = (5D)^2$	100,000 (1 Å, Extreme X-ray: EXR)
15-19	$F = (6D)^2$	100,000 (1 Å, Extreme X-ray: EXR)
20+	See Tunable Lasers, above	

If the laser is being designed for space combat use, divide the resulting effective range (kilometers) by 30,000 to get effective range in space combat hexes or range bands. Round to the nearest 0.01.

5C. Tunable Lasers

Note that tunable lasers must have their effective ranges calculated separately for the different wavelengths that they are capable of firing. This is done with the procedures above by using the correct focal modifier by tech level, but multiplying the resulting focal value F by the various wavelength range factors that are available to the weapon. Tunable lasers of a given tech level have available to them all wavelengths above them (i.e., at lower tech levels) on the table above.

This graph illustrates the problems of atmospheric absorption of laser energy by showing how far electromagnetic radiation can penetrate through the Earth's atmosphere from space. The graph shows radiation entering our atmosphere from space; the curve shows how far into the atmosphere the radiation gets before half of it is absorbed. In **Traveller**, denser atmospheres would have greater shaded area beneath the curves, while thin atmospheres would have less. Worlds with tainted atmospheres would have many more "spikes" where particular atmospheric components would absorb specific wavelengths. Studying this graph explains why our eyes see in the wavelengths that they do, as well as why radio works so well for us. Bear in mind that even where the graph seems to show complete transparency, such as in the visible bands, our atmosphere is not really transparent. Think of clouds, rainstorms, mist, haze, snow, and fog, which all increase the average absorption of our atmosphere.

5D. Atmospheric Performance

All laser energy is absorbed by planetary atmospheres to some extent, but this is especially the case with laser wavelengths shorter than visible light, i.e., ultraviolet and X-ray lasers. The effective range defined above is the laser's effective range in vacuum: in space or on the surface of airless worlds.

When the laser is to be used within atmospheres, the following modifications must be made to effective range. Although theoretically a laser might be rated for its performance in all potential atmospheres, in practice a laser need only be rated for the environment for which it is primarily intended, for example the atmosphere of the world on which it was designed, or in vacuum for a starship laser.

Atmospheric Range Modifiers

Atmosphere (UWP Code)	*Visible and Infrared* (Range Factors 3 and 20)*	*Ultraviolet, X Rays, and Beyond (Range Factors 33 and above)*
Vacuum (0)	1.0	1.0
Trace (1)	1.0	0.9
Very Thin (2, 3)	0.5	0.1
Thin (4, 5)	0.2	0.02
Standard (6, 7)	0.1	0.01
Dense (8, 9)	0.05	0.005
Exotic+ (A+)	0.01	0.001

*Although most infrared radiation is readily absorbed by atmospheres, atmospheres contain many "windows" in the infrared range in which specific IR wavelengths are only absorbed at about the same rate as visible light. Thus it is assumed that the infrared lasers in use are those which are designed to take advantage of these windows.

Effective range as adjusted by atmosphere can be used in different ways according to the purposes of the designer. If the laser is intended primarily for use in an atmosphere, the atmosphere adjusted effective range should probably be used when choosing a beam pointer (Step 6). If the laser is intended for space combat, its unadjusted effective range should be used to choose the beam pointer.

Planetary Bombardment: This is a specific application of the atmospheric modifier rules. This is not calculated in advance for each laser, but is calculated separately each time it is done.

First find the range to the world being bombarded, in hexes. Planetary bombardments from the same hex are given a default value of 0.5 hexes. Divide this range by the atmosphere modifier appropriate to the atmosphere type and laser wavelength from the table above. The result is the equivalent range in hexes to a target on the planetary surface, called the *atmosphere adjusted range.* Use this range to find the proper range band of the laser's rated range performance. If the range falls between two range bands, use the higher band. This gives the laser's damage performance. Difficulty of the firing task is still calculated according to the actual range.

If the adjusted range falls beyond the laser's extreme range, use its effective range along with the procedure defined in Step 7B below to determine if it has any damage performance left at that range.

If the target is an aircraft or spacecraft flying through the atmosphere at high altitude, cut this final atmosphere adjusted range in half.

6. DEFINE SHORT RANGE

6A. Large (Non-Hand-Held) Lasers

The beam pointer represents the integral fire control capabilities installed on the laser mount.

Select a beam pointer from the Fire Control chapter (Section 14). Note that range is given in kilometers and 30,000-km hexes/range bands for space combat. The listed range in km/hexes of the selected beam pointer will be the laser's short range for purposes of combat. Whenever possible, the beam pointer range should be equal to the laser's effective range to take full advantage of the laser's range-intensity performance.

When a laser has its performance adjusted for atmosphere, remember that its atmosphere-adjusted ranges are for purposes of damage calculation only. Its short range (and medium, long, and extreme ranges which are derived from it) based on installed beam pointer are still used for resolving hits.

6B. Small Arms (Hand-Held) Lasers

Small arms lasers include laser rifles, carbines, and pistols, as well as larger lasers used as man-portable infantry heavy weapons.

For small arms lasers, which are not fitted with beam pointers, short range is based on human aiming limits. These are calculated as follows.

Short Range (meters) = 200 × Configuration Multiplier

Configuration	*Cm*
One-Handed*	0.4
Two-Handed*	1.3
Optic Sights (TL 7)**	1.05
Optic Sights (TL 8)**	1.1
Optic Sights (TL 9+)**	1.15

*One-handed refers to pistols, fitted with only a pistol grip. Two-handed refers to weapons specifically designed to be fired with two hands, and thus include a stock instead of simply a pistol grip.

Some weapons are intended to be used exclusively from a tripod or vehicle pintle mount, and are only fitted with pistol grips. However, these weapons are considered to be two-handed for determining range.

**Mass and weight for these items is recorded in Step 10.

Round results of 299 meters to 300.

If two configuration descriptions apply to the same weapon, use both. Even if an optic sight is fitted to a two-handed weapon, the basic (iron sight) range should be calculated as well. This is necessary because an advanced sight (see the Small Arms Design chapter, page 97) might be installed later, and the advanced sight enhancement is applied to the basic range, not the optic sight range. The maximum short range for any small arm, after all modifications for optic or advanced sights, bipod and tripod effects, is always 300 meters.

Compare the short range derived above to the small arms laser's effective range, and use the shorter of the two for the laser's short range.

7. LASER COMBAT RATINGS

A laser's combat performance is rated in three areas: range performance, damage at those ranges, and penetration ratings at those ranges.

7A. Combat Range Bands

All combat ranges are based on the laser's short range, established in Step 6. For lasers intended for planetary combat, these ranges should be expressed in kilometers; for spacecraft lasers, these ranges should be expressed in starship combat hexes/range bands in whole numbers.

Medium range = Short range × 2
Long range = Short range × 4
Extreme range = Short range × 8

7B. Damage Value

Define the laser's damage characteristics at its short, medium, long, and extreme range bands.

Lasers do damage to enemy nonpersonnel targets (i.e., vehicles, structures, spacecraft) based on their *damage value* (DV). Damage value is calculated as follows (round to nearest whole number):

$$DV = 2.5\sqrt{I}$$

where I is the weapon's *intensity* (units for intensity are Mj per square centimeter) at that range. Intensity is derived as follows.

For each of the four range bands, divide that range band's actual range (from 7A, in kilometers or hexes, as appropriate to the type of weapon) by the laser's effective range (in the same units) from Step 5. Round this result to the nearest 0.01, but *always* treat results of less than 1 as 1. This figure is used as R in the next formula:

$$I = DE\ (1+R^2)$$

where
DE is discharge energy from Step 4 above.

7C. Penetration Rating

Lasers penetrate enemy armor based on their *penetration value*. Penetration value is not derived separately, but is calculated from the laser's DV by using the laser's *penetration rating* (PR). DV÷PR = penetration value; penetration value × PR = DV. Penetration rating is calculated as follows.

Take the intensity (I) as calculated in 7B above, and apply the formula

$$(\sqrt{I}) \times 0.8 = IPR$$

IPR is the *inverse penetration rating*. Round IPR decimals as follows: 0.5 and above rounds up to the next whole number; less than 0.5 rounds down. Now take the inverse of the IPR by dividing 1 by it. This is the laser's penetration rating, PR. Leave this number expressed as the fraction, $^1/_{IPR}$. For example, an IPR of 3.49 rounds to IPR of 3 and the PR is expressed as $^1/_3$. Intensities that yield IPRs of less than 0.5 (an intensity of 0.390625 Mj per cm^2 yields an IPR of 0.5, which rounds up to 1) have a final penetration rating of *Nil*, meaning that they have no penetrative capability. This is because a laser's damage value and penetration capacity both decrease at the same rate, and that at less than 0.39 Mj there is not sufficient damage value in the shot to allow penetration (i.e., 1 point of damage value required by a penetration rating of 1 to penetrate an armor value of 1).

Note: For purposes of target penetration, lasers are only affected by personal armor of a rigid nature. Rigid armor is defined in the Personal Armor section (Section 2), and consists of metallic and hard ceramic armor. Non-rigid, or flexible personal armor (leather, ballistic cloth, and ballistic weave) is always treated as no armor by laser hits. Metal chain mail, because of its porous nature, is also treated as no armor. Metallic or ceramic insert plates added to flexible armor are treated as rigid armor.

"Natural" armor on animals, such as tough skin or bony plates, is also treated as no armor by lasers. However, natural cover used by personnel, such as trees, fences, stone walls, dirt berms, etc., are not ignored by lasers, but must be penetrated before personnel sheltering behind them may be hit.

7D. Personnel Damage Dice

The damage that a laser does to a personnel target (which includes animals) is calculated differently from the damage value calculated in 7B above. Damage done to personnel is based on damage dice, which is also based on the laser's intensity at the range in question according to the formula

$$50\sqrt{Mj}$$

For small arms lasers, particularly those with penetration ratings of Nil, the number of damage dice can be calculated in advance. However, because damage capacity lost when penetrating armor is calculated in terms of *damage value* and not *damage dice*, it is best to calculate damage dice versus a personnel target after penetration has occurred. Multiply the remaining damage value by 20, and the result is the number of damage dice done to the target (DV × 20 = damage dice).

8. POWER SOURCE AND RATE OF FIRE

Most lasers are powered by electrical energy supplied by a vehicle power plant and stored in a form of capacitor until the weapon is fired. However, at TL 11 and above, lasers can also be supplied by stored chemical energy. Stored chemical energy is popular for use with small arms lasers because the chemical laser cartridges (CLCs) are easier to use than cumbersome rechargeable power packs.

There is a drawback with CLCs, however, which makes them less desirable for use in spacecraft, which is the fact that the chemicals contained in the cartridges and produced in the firing process are highly corrosive, flammable, and poisonous. This presents a great threat to any craft which must dispose of these byproducts or which sustains an ammunition hit. Because spacecraft or vehicles intended for use in vacuum or hostile atmospheres cannot flush and replenish their atmospheres from outside sources of oxygen, CLCs are generally not chosen for their lasers.

8A. Direct Electrical Power

Direct electrical power requires the installation of a homopolar generator (HPG), which is a type of capacitor in the form of an electro-mechanical flywheel. The HPG must be of sufficient size to store the laser's one-shot input energy (IE) as defined in Step 4. Calculate the volume of HPG needed by multiplying the laser's input energy in Mj by the value on the HPG table in the Power Production chapter (Section 8).

In large vehicle- and ship-mounted lasers, the HPG is added into the total mass and volume of the entire laser. For small arms lasers, the HPG is carried separately in a backpack or beltpack.

Rate of Fire: Define the laser's rate of fire (ROF). This rate will be expressed differently depending upon whether the laser is intended for space combat or ground combat, as space combat turns are 30 minutes in length, while ground combat turns are five seconds. Rate of fire will define the amount of power input that the weapon needs, and may require an increase in the volume, mass, and price of the focal array.

Rate of fire for a direct electrical input (HPG) laser is limited by available input power, and structural qualities of the laser's focal array. The HPG itself does not limit the ROF, regardless of tech level. The size of the HPG is the same regardless of the laser's rate of fire, as it must only store enough energy for one shot at a time, regardless of how often those shots are fired.

Space Combat ROF: All space combat lasers must have a rate of fire of at least 10 shots per 30-minute turn, or one shot every three minutes. This is equivalent to a ground combat ROF of 1/36, one shot every 36 turns. When converting space combat ROFs to ground combat, divide the ROF per 30 minutes by 360. If this number is greater than 1, round any fractions *down*. This is the number of shots per five-second combat turn.

If it is less than 1, take the inverse (i.e., divide 1 by that number), and round fractions *up*. The result is the number of five-second combat turns required for each shot. Express this number as a fraction, i.e., one shot every 5 turns is 1/5, one shot every 36 turns is 1/36, etc.

For purposes of space combat, lasers gain to-hit benefits for higher ROFs as shown in the table below.

Lasers process a tremendous amount of energy each time they fire, and this energy creates thermal effects throughout the focal array. These thermal effects result in minute deformations of the focal array itself, which affect the accuracy of later shots. Enough of a thermal effect will actually damage the laser. At space combat ROFs of 200 and higher, the focal array of a direct electrical input laser must be increased in size to allow for active and passive measures of heat dispersion as shown on the Rate of Fire Benefits in Space Combat table. This focal array multiplier is applied to the FA volume, from which mass and price are then derived.

Rate of Fire Benefits in Space Combat

Space Combat ROF (Shots per 30-minute turn)	*Equivalent Benefit (In Diff Mods to Fire Task)*	*Ground Combat ROF (Shots per 5-second turn)*	*FA Mult*
10	None	1/36	1
50	–1 difficulty levels	1/8	1*
100	–2 difficulty levels	1/4	1*
200	–3 difficulty levels	1/2	2
400	–4 difficulty levels	1	4
800	–5 difficulty levels	2	8

*There is no penalty for firing a laser at one of these higher power levels if the laser is mounted in a vehicle or starship which is designed from the outset to provide sufficient power for the higher ROF (50 or 100 shots). However, lasers which were not installed with the higher power levels may fire at these levels if sufficient power is made available by diverting it from other systems. Unfortunately, because of the extra strain this places on power couplings, HPGs, etc., a Ship's Engineering task must be rolled each turn this is attempted. The difficulty level is Difficult if the ROF is raised one step (from 10 to 50 or from 50 to 100) over the installed power allocation, or Formidable if raised two steps (10 to 100). Failure at this roll indicates a System Reset result (see the **TNE** Space Combat chapter, or **Brilliant Lances: Traveller Starship Combat**), with the additional penalty that the laser may not fire on the current turn. Catastrophic Failure indicates more severe damage. Roll 1D10: 1-5 indicates a Degraded Performance result in addition to System Reset; 6-10 indicates a major hit on the laser.

Lasers may only fire at the 200+ ROFs if they are designed as such with beefed-up focal arrays.

Ground Combat ROF: To be really useful, ground combat lasers should have an ROF of at least one shot per turn. Rate of fire for a direct electrical input (HPG) laser is limited by available input power, and structural qualities of the laser's focal array. The HPG itself does not limit the ROF, regardless of tech level.

Like space lasers, ground combat direct electrical lasers need to have their focal arrays beefed up in order to fire at high ROFs.

Rate of Fire Benefits in Ground Combat

Ground Combat ROF (Shots per 5-second turn)	*FA Multiplier*
1/2	2
1	4
2	8
3	12
4	16
5	20
15 (Automatic: 3-round bursts)	60
25 (Automatic: 5-round bursts)	100
50 (Automatic: 10-round bursts)	200
250 (Automatic: 50-round bursts)	1000

Note: Lasers with an ROF of 15+ count as automatic weapons for purposes of firing at aircraft

Power Input: Power input in megawatts (MW) is calculated differently for space combat and planetary combat lasers. Although they are calculated differently, space and planetary combat power input values are absolute values, as they are both based on MW input per second.

Space Combat Lasers: Multiply ROF times the laser's input energy (IE) as determined in Step 4. This is the total number of megajoules needed over the course of a 30-minute turn. Divide this result by 1800 to find the MW of power that must be allocated to operate the weapon.

Planetary Combat Lasers: Multiply ROF times the laser's input energy (IE) as determined in Step 4. This is the total number of megajoules consumed by the weapon each five-second turn. Divide this result by 5 to find the MW of power that must be allocated to operate the weapon.

Direct electrical power input requirements are usually met by power plants in vehicles and spacecraft, but are typically met by battery packs or fuel cells in the case of small arms lasers. These battery packs or fuel cells are carried in the same backpack as the homopolar generator.

8B. Chemical Laser Cartridge

Powering a laser by chemical laser cartridge (CLC) allows the laser to function in the fashion of a conventional firearm or artillery piece, in that each shot consumes an ammunition cartridge, whose empty casing is then ejected allowing the laser to be reloaded and fired again.

A chemical laser cartridge is quite different from the similarly named cartridges used by the explosive power generators (EPGs) in the Power Production chapter (Section 8). The chemical reactions generated by CLCs are not efficient for producing electrical energy. Rather, they produce a population inversion of energized atoms and/or molecules which can be manipulated to release photons of a particular wavelength which are focused into a laser beam.

Each CLC contains the full input energy required for the shot as calculated in Step 4 above. The chart below shows the amount of Mj per kilogram that can be chemically stored for release as laser energy, based on tech level. To calculate the mass of chemicals needed, divide the IE (in Mj) from Step 4 by the number on the chart, and the result is the required amount of chemicals in kilograms.

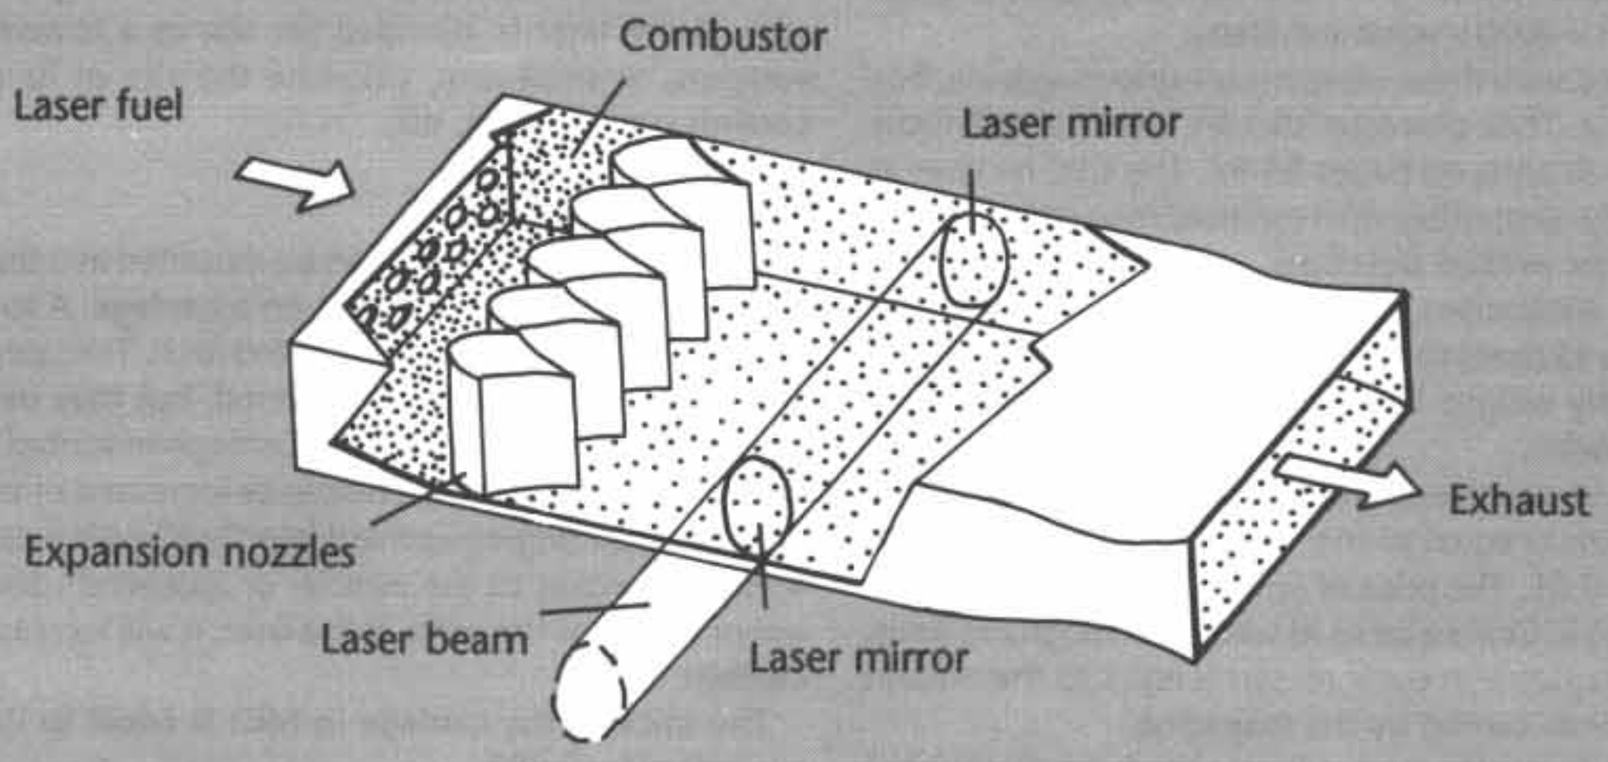
TL	*Mj per kg*
11-12	1
13-15	2
16-19	3
20+	4

Once the required mass of chemicals is known, the chemical cartridge itself must be designed. The simplest way to do this is to design a cylindrical cartridge three times as long as its diameter. CLC chemicals have a volume of 0.1 liters per kilogram (10 kg per liter; other units may be more convenient for very large or very small lasers; CLC chemicals also have a volume of 0.1 cubic meters per tonne [10 tonnes per cubic meter] or 0.1 cubic centimeters per gram [10 grams per cc]). Cartridge price is Cr30 per Mj of input energy.

To find the dimensions of the 3×D cartridge, use the equation:

$$0.376 \times \sqrt[3]{\text{Volume}} = \text{radius of cartridge}$$

Cartridge diameter is 2 × radius, and cartridge length is 6 × radius. Designers will frequently prefer to change the diameter into a round number and recalculate the cartridge length to make up for the difference, using the formula:



$$\pi r^2 \times \text{length} = \text{cartridge volume, where } \pi = 3.1416$$

Rate of Fire: Rate of fire is defined as above for direct electrical input lasers.

Rate of fire with CLCs is limited by the weapon's purge cycle, the rate at which it burns and disposes of the CLC chemicals. CLC lasers create energy by releasing the chemical energy stored in the cartridges. These chemicals are combined in a controlled fashion in the laser's *combustor*. It is in the combustor, filled with energetic atoms and/or molecules, that the laser beam is generated. As the energy is withdrawn from these molecules in the form of energetic photons, the used chemical fuel is removed by the *evacuator* to prepare for the next shot. Depending upon the environment, this highly caustic, highly poisonous spent fuel is either stored in a cannister or expelled out of the laser. This evacuation cycle is combined with the cooling cycle for greater efficiency.

Unlike direct electrical lasers, ROFs above a certain level do not require the increase in size of the focal array. Instead, the volume of the combustor/evacuator system yields the maximum rate of fire.

All CLCs have a base combustor/evacuator volume of 0.055 cubic meters (55 liters) per Mj of input energy (IE, defined in Step 4) per

High-Power Chemical Laser

Chemical fuel extracted from the cartridge is burned in the combustor at left, and its pressure causes it to pass through the expansion nozzles into the laser-generation cavity. By firing a tiny starting pulse of photons, energy from the hot gas is extracted in the form of photons of the same wavelength, which are then bounced back and forth between the mirrors, stimulating more photon emission from the gas. The pressure of the hot gas causes a continuous flow from the combustor to the exhaust. But because the pressure in the combustor is often less than 1 atmosphere, a vacuum evacuator must be installed at the exhaust unless the laser is being vented directly into space. The laser is fired to the lower left.

CLC cartridge. This yields an ROF of one shot per second (five shots per combat turn). Volumes greater or less than this amount yield correspondingly higher or lower rates of fire.

Divide the actual volume of the combustor/evacuator by the base volume (0.055 m³/55 liters × IE), and multiply the result by 5. This is the number of shots per combat turn that can be fired. Combustor/evacuators mass 1 tonne per cubic meter (1 kg per liter) and cost Cr0.5 per cubic meter (Cr500 per liter). This includes weight and volume for a closed-cycle cooling system. The cooling system requires overhaul and recharging of fluids after the equivalent of 1000 turns of maximum ROF fire. This recharging costs Cr100 times the cooling system's displacement in liters.

CLC Laser Ammunition Feed: CLC lasers require an ammunition feed system. For small arms lasers (light focal arrays), this is a receiver-magazine assembly similar to those used by normal slug-firing small arms. For non-man-portable lasers (heavy focal arrays), the feed system is an electrical action with attached autoloader. Some heavy weapons may fall between this range; although they are equipped with light focal arrays, it is more convenient to equip them with heavy autoloaders.

The maximum CLC cartridge feed rate is five cartridges per five-second turn. This is sufficient for full semiautomatic fire. In order to achieve automatic ROF levels, multiple laser pulses are extracted from a single CLC cartridge. Burst size can be 3, 5, or 10, depending upon the amount of energy stored in the cartridge. Simply design cartridges with sufficient input energy for the full number of shots in the burst. Be sure to note in the weapon's listing that only one cartridge is fired per automatic *burst*, rather than the usual one cartridge per automatic *shot*.

Small Arms with Magazines: Each weapon requires a receiver, which extracts the CLC from the magazine, holds the cartridge while its contents are explosively combined in the combustor, and then ejects the spent round to make space for a new one. The receiver's volume is equal to 80 times the volume of the CLC cartridge, weighs 1 kilogram per liter (1 gram per cubic centimeter), and has a cost in credits equal to its volume in liters multiplied by 2000 (Cr = 2000 × volume in liters).

Magazine types used with these weapons are grip magazine, box magazine, and cassette. Their characteristics are identical with those described for CPR small arms on pages 96-97. The CLC receiver as described above is fully compatible with the listed magazine descriptions, and CLCs are not necked cartridges.

Large Lasers with Autoloaders: The volume of the action and autoloader is equal to 35 times the volume of a single CLC round for the laser. The assembly weighs 1 tonne per cubic meter and costs MCr0.01 per cubic meter.

The magazine may be any size desired by the designer. The weight of the empty magazine is equal to the weight of all of the rounds carried multiplied by 0.01. The price of an empty magazine (sometimes called a hopper) in Cr is equal to its weight in kilograms times 5. The volume of a magazine in cubic meters is equal to the mass in tonnes ÷ 5 of the rounds carried by the magazine.

Reload time, in five-second turns, is equal to the loaded weight of a magazine in tonnes multiplied by 10, rounding fractions up.

Wavelength Tuning of CLC Lasers: CLC lasers may have tunable wavelengths as discussed above in Steps 1 and 5. However, because the wavelength of a CLC's beam is controlled by the specific chemical reaction taking place in its combustor, it must have a combustor which is modified to allow for various chemical reactions, and the laser must also be supplied with a variety of ammunition which will generate a variety of wavelengths. A tunable combustor/evacuator assembly merely costs twice the normal price (Cr1 per cubic meter/Cr1000 per liter) listed above. CLC ammunition for specific wavelengths has no difference in price, but any players or military force must take steps to ensure that they are supplied with the correct ammunition for their needs. In addition, referees may stipulate that some worlds have specific compounds in their atmospheres that absorb common laser wavelengths that are otherwise normally effective in that atmosphere type (this should especially be the case in tainted atmospheres). As with all tunable lasers, tunable CLCs must have their effective ranges calculated separately for the different wavelengths that it fires.

9. CREW

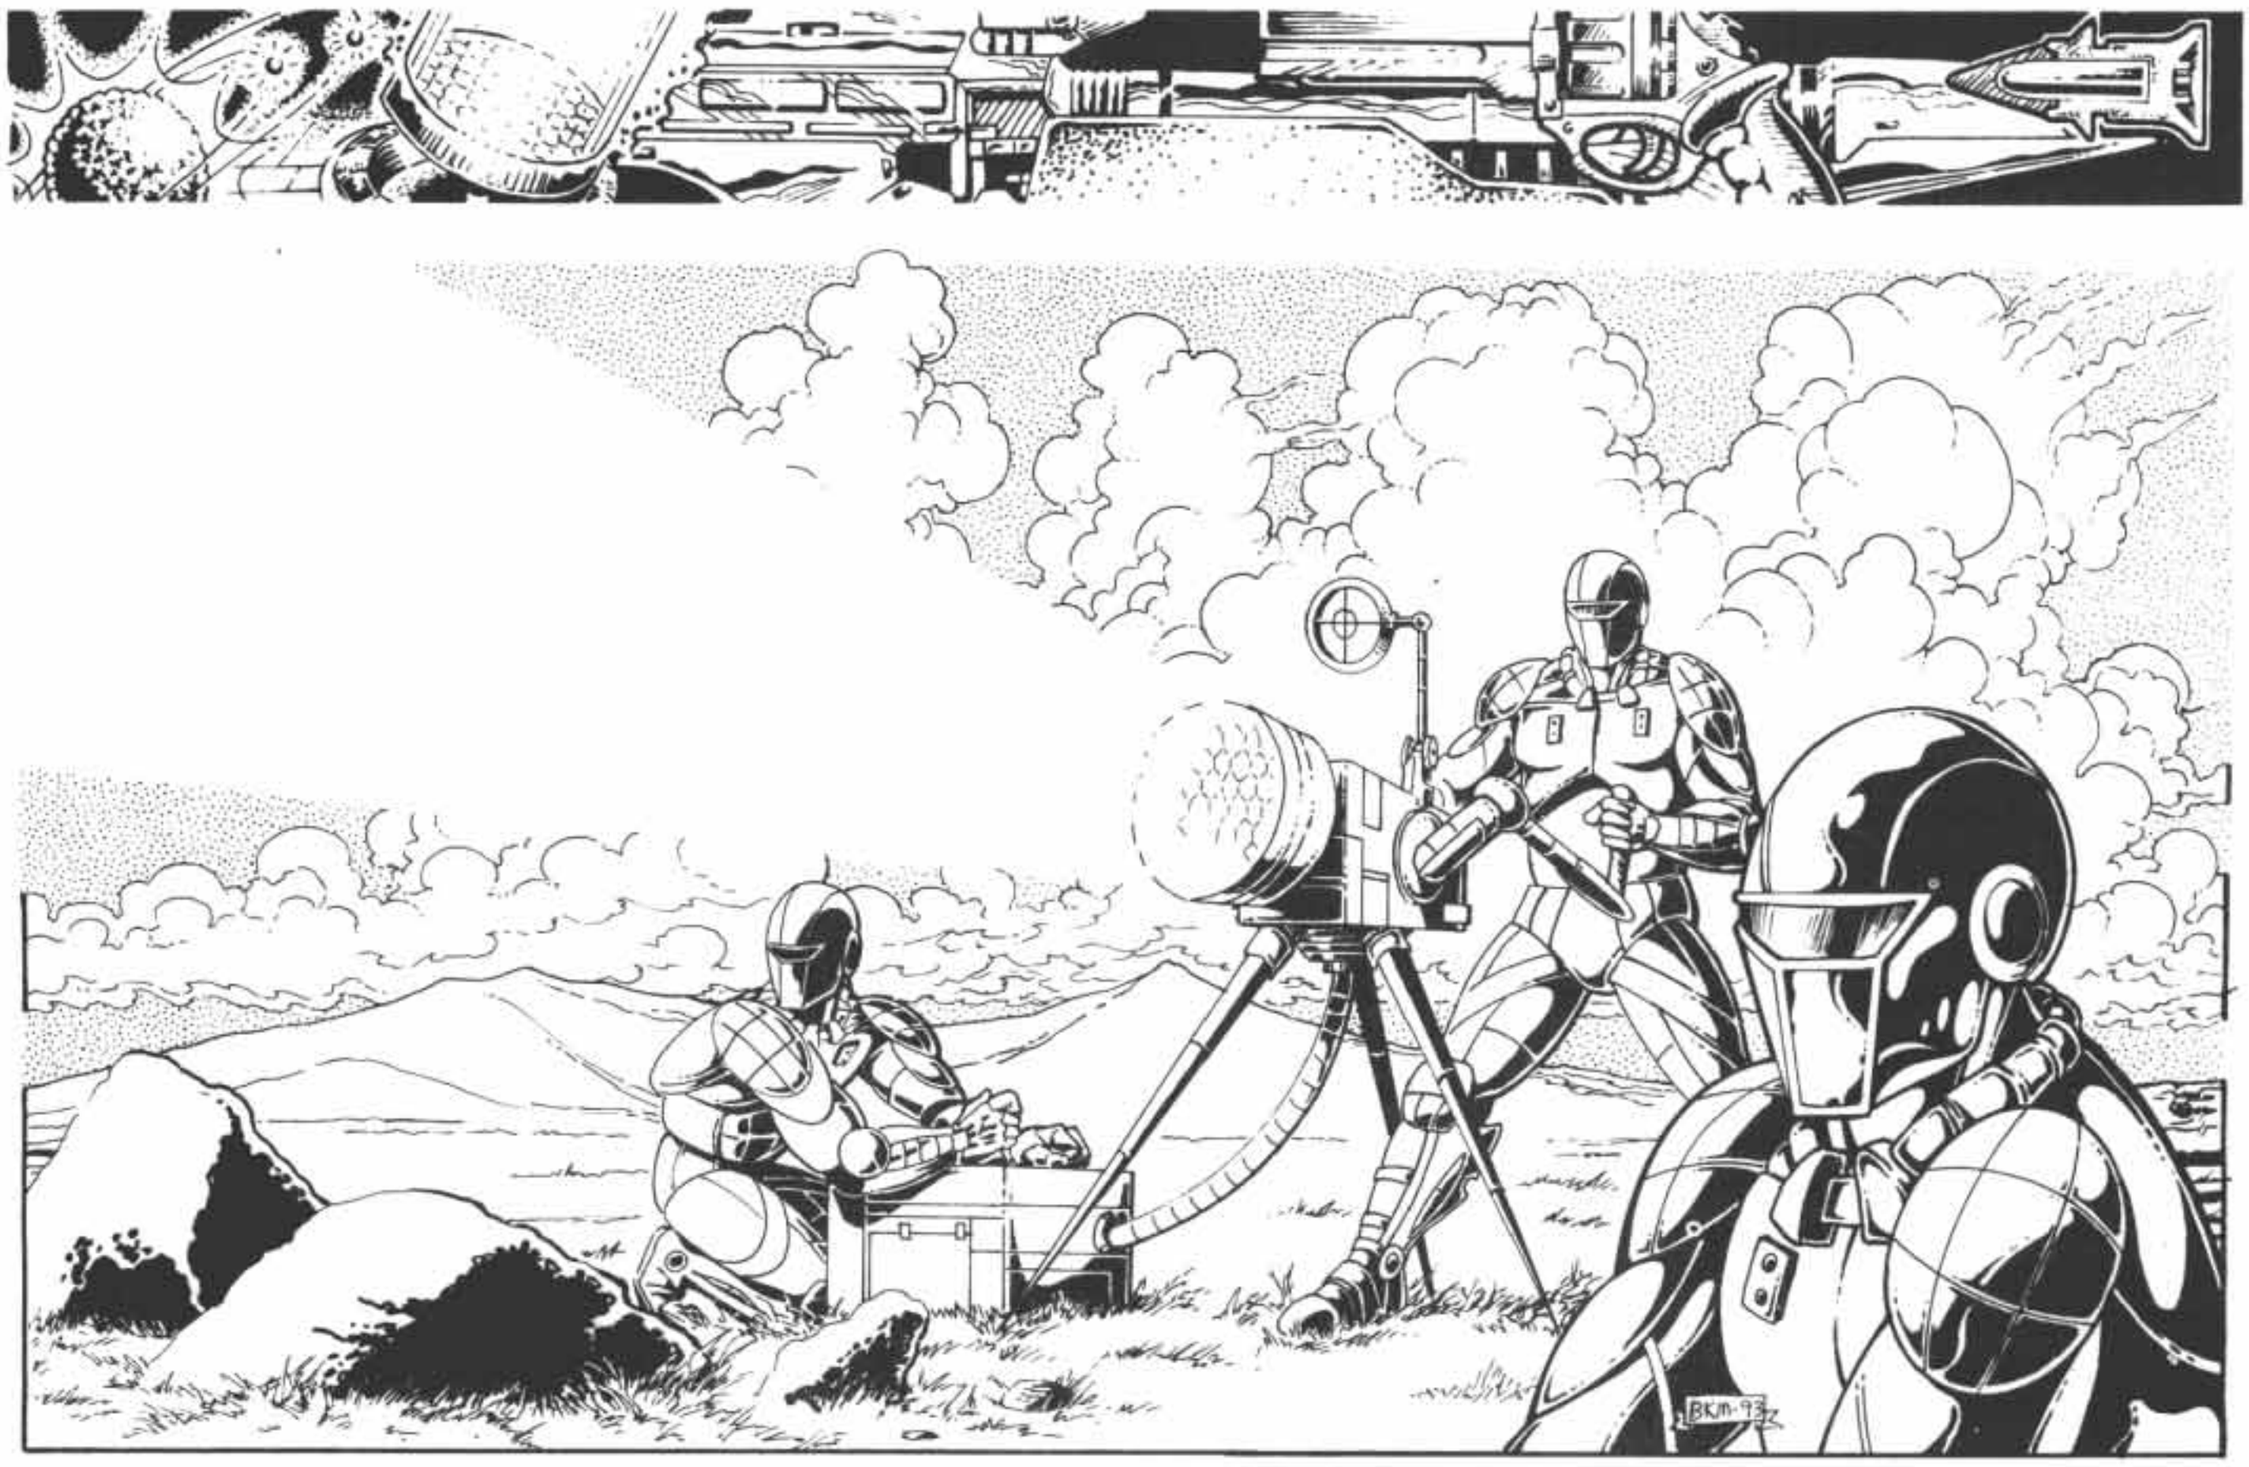
Any vehicle- or spacecraft-mounted weapon must be designated as crewed or uncrewed. A laser can only be left uncrewed if the vehicle in which it is installed is equipped with one or more master fire directors (MFDs) which will be used to control it remotely. In the event of the destruction of all of a vehicle's MFDs, an uncrewed laser may not be fired. A crewed laser may also be fired remotely by an MFD, but can also be fired under "local control" by the gunner if the MFD cannot be used to fire the laser.

Small arms or heavy weapons lasers do not need workstations, but ground turret and carriage-mounted lasers do, unless they are wired into a ground-based MFD. If it is to be crewed, the weapon must have a gunner's workstation installed with the characteristics of a normal workstation as presented in the Controls chapter (Section 4).

Heavy weapons lasers require a crew of one, although additional crew may be required to help carry the weapon and its mount, and (in the case of CLC lasers) to assist with ammunition. On average, troops can carry 72 kg each at the burdened rate, but this must also include all of their other equipment.

10. LASER FURNISHINGS AND SUPPORTING HARDWARE

If the laser is to be mounted aboard a starship or vehicle, skip this step. If the laser is intended for use as a towed weapon, heavy weapon, or small arm, calculate the size of its carriage, mount, cooling system, stock, etc.



10A. Carriage

A heavy focal array laser can be mounted as a towed or otherwise movable weapon by placing it on a carriage. A towed carriage has the same mass as the laser mounted on it. The laser must include an HPG if it is direct electrical-powered, but may be plugged in to a power source at its destination. Carriage-mounted lasers have an all-around armor value of 1. This can be increased by enclosing the laser and its supporting equipment in a "hull" with a certain thickness of armor according to the vehicle- or spacecraft-design rules. As this armor increases the mass of the laser, it will increase the mass of the carriage as well.

The price of the carriage in MCr is equal to its mass in tonnes multiplied by 0.002.

10B. Mounts

Very large or even normal-sized small arms lasers (light focal arrays) may be provided with tripods or bipods for use as heavy weapons. When fired from a bipod, short range is increased by 30% (multiply by 1.3); when fired from a tripod, short range is doubled (multiply by 2). However, short range may never be modified to greater than 300 meters.

Bipods weigh 0.1 times the loaded weight of the laser; their price in credits is 50 plus the bipod's weight in kilograms times 10 (50 + [10 × weight]). The weight of a bipod is included in the final weight of a laser, but does not count against its volume.

The weight of a tripod is equal to half the fully loaded weight of the laser times 0.5; the price in credits is 100 plus the tripod's weight in kilograms times 10 (100 + [10 × weight]). The weight of a tripod is not included in the final weight of a laser.

10C. Small Arms Cooling Systems

CLC-powered lasers have their cooling systems integral to their combustor/evacuator assemblies. Only light focal array lasers powered by direct electrical input need to undergo this step.

Take the per-shot input energy (IE) calculated in Step 4 and multiply it by 10 (IE x 10). The result is the volume of the closed-cycle cooling system in liters. At least 50% of this system must be placed in the weapon itself, and at least 20% must go into the backpack. The remaining 30% may be placed in either the weapon or backpack.

The cooling system masses 2 kilograms per liter (2 grams per cubic centimeter) and costs 1700 credits per liter.

The cooling system requires overhaul and recharging of fluids after the equivalent of 1000 turns of maximum ROF fire. This recharging costs Cr100 times the cooling system's displacement in liters.

10D. Small Arms Body and Stocks

Add together the volume of the components that will be fitted into the weapon itself, separate from its backpack. For direct electrical weapons, this is focal array and cooling system; for CLC lasers, this is focal array, combustor/evacuator, and receiver (magazines are not part of the "empty" volume).

Weapon Body: Multiply this volume (in liters or cubic centimeters, whichever unit the designer is using) by 0.05. This is the volume of the weapon's structural body, which encloses and protects the weapon's components. Because lasers are finely calibrated and relatively fragile weapons, they must be "ruggedized" if they are to be fitted with additional items such as attached grenade launchers or rifle grenade adapters. Double the structural body above for ruggedization (to 0.1 × volume).

These weapons are still too fragile to function in combat as melee weapons, and will not function after being used as clubs. If a designer wishes for a laser to be fitted with a bayonet lug for use as a melee weapon, the body volume must be doubled again (four times the basic volume or 0.2 × volume).

Mass of the body is 1 kilogram per liter (1 gram per cubic centimeter), and price is 100 credits per liter (0.1 credits per cubic centimeter).

Weapon Length: To find the length of the weapon, take its total volume including its body, and convert into cubic centimeters. (For those not already working in cubic centimeters, 1 liter = 1000 cubic centimeters, 1 cubic meter = 1,000,000 cubic centimeters.)

Take the cube root of the volume, and multiply the result by the configuration multiplier. Direct electrical input and CLC lasers have different configurations, with CLCs being shorter, bulkier, and more robust looking, and direct electrical lasers being lighter, longer, and finer-lined.

Type	*Length Multiplier*
Direct Electrical Input	4.3
Chemical Laser	3.4

The result is the weapon's basic length in centimeters before stocks and optional items below are added.

Additional features may be added to the weapon, and may increase its length.

Bayonet Lugs: Bayonet lugs are simple standardized brackets at the end of the weapon barrel. A bayonet lug costs nothing, has negligible mass, and adds no length to the weapon.

To be most effective, a bayonet must be mounted on a well-balanced weapon with sufficient length to allow it to be used as a spear point. As a result, only weapons with a bulk (see 11F below) of 4 or more may profitably benefit from a bayonet lug. Shorter weapons may have them but the mounted bayonet counts as a short range (instead of long range) melee weapon and suffers a +1 Difficulty modifier for its chance to hit in armed melee combat. The laser's structural body must be ruggedized to the 4 × level for a bayonet lug.

Grenade Adapter: For obvious reasons, lasers may not fire standard shot trap rifle grenades. They may, however, fire RAM (Rocket Assisted Multipurpose) rifle grenades (RAMRiGs). A grenade adapter allows the firing of RAMRiGs, adds 5 cm to the length of the weapon and costs Cr50. The laser's structural body must be ruggedized to the 2 × level for a grenade adapter.

Attached Grenade Launcher: Lasers may have attached (underslung) grenade launchers added to them. See the Launchers chapter for details on their design. The launcher may not be greater than one half the length of the laser. The laser's structural body must be ruggedized to the 2 × level for an attached grenade launcher.

Stocks: If the weapon's length (exclusive of RAM grenade adapters) is greater than 40 centimeters, it is presumed to already be configured as a two-handed weapon, and need only be fitted with a bullpup stock from the table below. If shorter, it must be fitted with a stock to function as a two-handed weapon to gain the range benefits in Step 6B above. If left as a one-handed weapon, it must be fitted with a pistol grip.

The weapon's final length is its base length derived above plus the length of any stocks fitted, plus the length added by a rifle grenade adapter (if any).

TL	*Type*	*Length (cm)*	*Mass (kg)*	*Credits*
4	Wood pistol grip	0	0.2	5
4	Wooden stock	25	1	25
4	Carbine stock	25	0.7	20
5	Hollow pistol grip	0	0.1	25
6	Folding stock	5/25	0.5	50
7	Plastic stock	25	0.5	30
7	Bullpup	5	0.1	10

10E. Sights

Because light focal arrays may not be fitted with beam pointers, they must be fitted with either small arms sights, or sometimes direct fire controls for heavy weapons. For direct fire controls, see the Fire Control chapter (Section 14).

If optic sights were specified in Step 6B above, their price, volume, and mass must be added to the laser. These are mounted outside of the laser's structural body, so are specified at this point, and their volume is added to the already calculated volume. Volume of all sights listed below is one liter per kilogram.

Optic Sights

TL	*Range*	*Mass (kg)*	*Price (Cr)*
7	×1.05	0.1	150
8	×1.1	0.1	150
9	×1.15	0.1	150

For advanced sights, such as laser, telescopic, and electronic, see the Small Arms chapter, pages 97-98.

10F. Small Arms Backpacks

Small arms laser backpacks are only needed by direct electrical input lasers. They contain the full volume and mass of the HPG and power supply, plus power supply fuel if necessary, and 20-50% of the cooling system.

Total the volume of the included components, and convert the results into liters. Multiply the volume in liters by 0.3 to get the mass, in kilograms, of the backpack casing. The volume of the backpack is equal to the volume of its contents, calculated above. The casing provides an armor value of 1 to the contents, and costs 3 credits per liter of volume. Armor protection may be increased by increasing these values (doubling the casing mass and price double the armor value, and so on).

The weight and cost of the cable connecting the backpack to the weapon is subsumed in the weights and costs of those items.

11. PHYSICAL CHARACTERISTICS

Add up or bring down the above components to obtain the following total figures for the gun.

11A. Volume

In cubic meters. Add focal array volume (as adjusted by ROF), beam pointer volume, HPG or combustor/evacuator volume, CLC feed system (if any), gunner's workstation volume, carriage volume (if any), and any small arms systems.

11B. Mass

In tonnes. Add focal array mass (as adjusted by ROF), beam pointer mass, HPG or combustor/evacuator mass, CLC feed system mass (if any), gunner's workstation mass, carriage mass (if any), and any small arms systems.

11C. Price

In MCr. Add focal array price (as adjusted by ROF), beam pointer price, HPG or combustor/evacuator price, CLC feed system price (if any), gunner's workstation price, carriage price (if any), and any small arms systems.

11D. Power Requirements

In MW, if direct-electrical type. Carry down from Step 8A above. If CLC, power requirement is limited to description of the size of its ammunition and magazines from step 8B.

11E. Surface Area

Surface area of a laser for purposes of installation on a starship or vehicle only is equal to its focal area surface area as calculated in Step 4, or its bay surface area as calculated in Step 3.

11F. Bulk

For small arms lasers only, calculate the bulk by taking the length of the weapon in centimeters and dividing by 15. Drop fractions. The result is its bulk.

11G. Recoil

Lasers have no recoil.

11H. Combat Performance

Short range, medium range, long range, and extreme range in km and/or space combat hexes, plus damage values at those ranges, along with ROF, listing any –difficulty modifiers as applicable. Carry down from Steps 7 and 8C.

CHAPTER 9
Munitions

This chapter covers the variety of projectiles fired by weapons, excluding small arms projectiles. These projectiles have various functions. This chapter's design sequence will be broken into three general parts: warheads, propellant, and guidance. Warheads are dealt with first, since even the simplest projectile has a warhead, even if it is only a solid metal shot. Mass driver projectiles and gravity bombs usually consist solely of a warhead.

CPR gun projectiles have a propellant charge which is consumed in the gun itself. CPR gun projectiles which also have a small rocket for additional range are called RAP (rocket-assisted projectile) ammunition. If a solid-fuel rocket motor is attached to a warhead, the warhead becomes a free-flight (FF) rocket.

If a guidance package is attached to an unpowered warhead, it becomes either a cannon-launched guided projectile (CLGP) or a guided bomb. If a guidance package is attached to a rocket-propelled warhead, it becomes a guided missile.

WARHEADS

Warheads are the business end of any munition. Designing warheads proceeds in the following order.

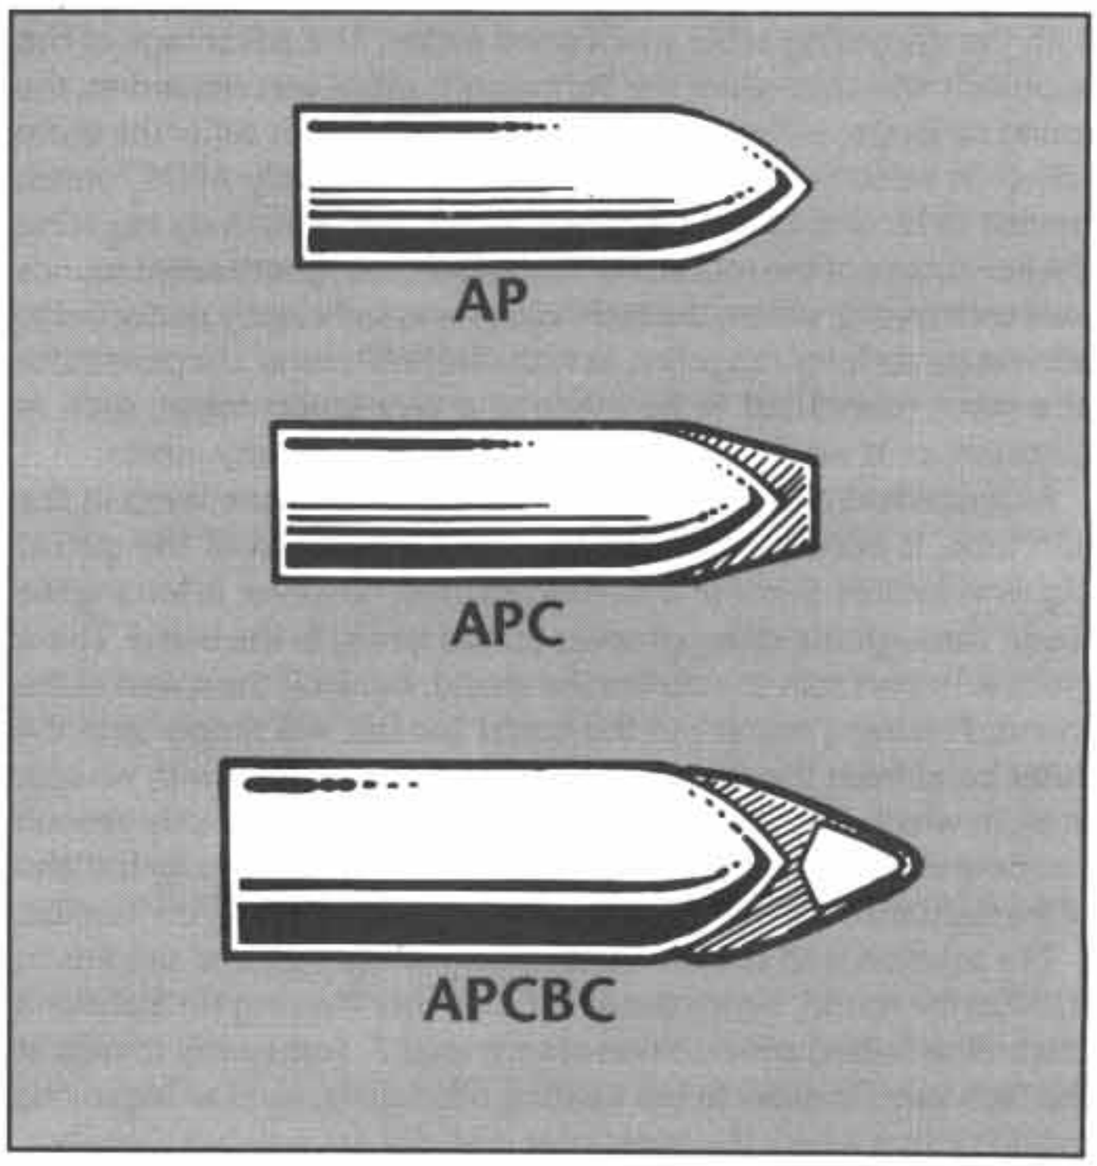
A. Specify Warhead Type: A number of different warhead types are available, each with its own specialized function.

1. High Explosive (HE): High explosive is probably the most common warhead in use. The warhead is hollow and filled with an explosive bursting charge and fused to detonate under a variety of conditions (impact, altitude, proximity, delay, etc.) The metallic warhead casing is often scored internally or lined with scored wire to produce the maximum number of lethal fragments.

2. Kinetic Energy Armor Piercing (KEAP): The earliest gunpowder artillery was used in siege work to batter down the enemy's walls, and so penetration of armor (stone armor in this case) has been an issue of gun design from the very beginning. The ability of a gun to penetrate metallic armor has been addressed urgently and scientifically ever since the appearance of the first ironclad warships in the mid-19th century.

In general terms, a gun's projectile penetrates armor by means of kinetic energy, and so the greater the muzzle energy, the greater the penetration of the gun, all other things being equal. All other things are seldom equal, however. A round with a smaller frontal area will penetrate more armor than a round with identical muzzle energy and a larger frontal area, as the energy of the round is concentrated on a smaller part of the armor, giving more energy per square centimeter.

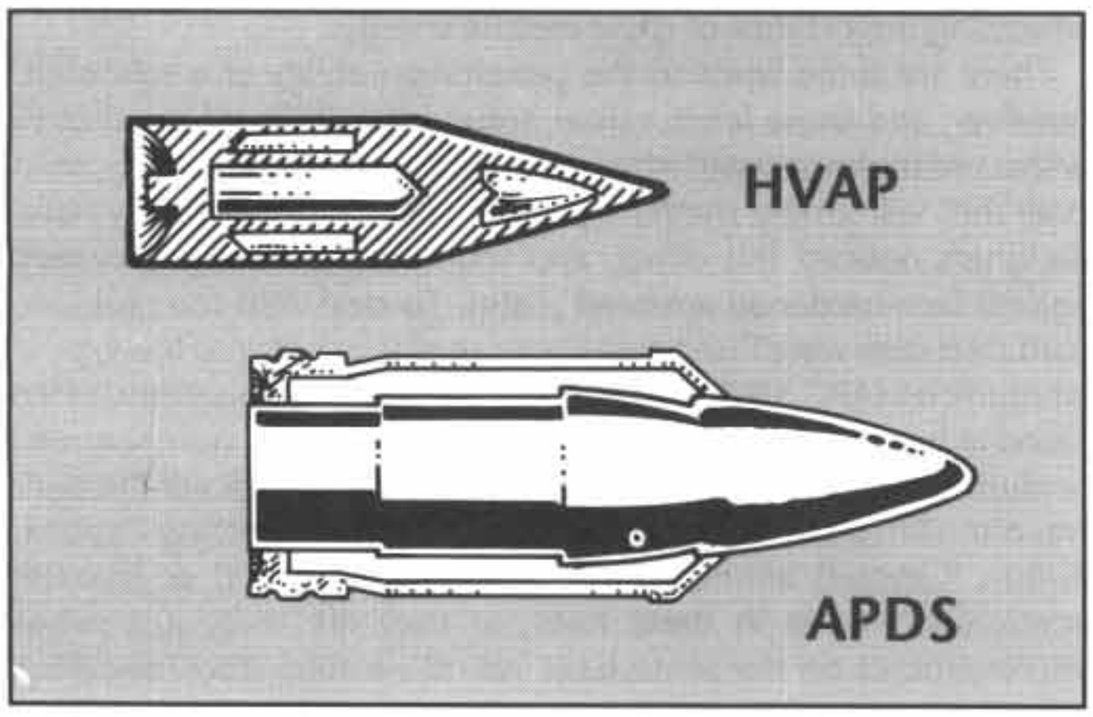
This is part of the reason discarding sabot rounds have greater penetration than normal rounds. The penetrator is a subcaliber rod encased in a lightweight sabot (pronounced SAY-bow) which fills the space around the penetrator in the gun barrel. Once the round leaves the gun, the sabot falls away (hence the term *discarding* sabot) leaving the penetrator to fly on alone to the target. When it strikes, the full energy of the round is concentrated on the smaller frontal area of the penetrator.



The above discussion should not leave the impression, however, that penetration is a simple matter of joules per square centimeter of armor contacted; it is not. Overall muzzle energy is a far more powerful predictor of penetration than energy per square centimeter contacted, since certain minimum energies are required to disrupt the integrity of armor of a given thickness and hardness.

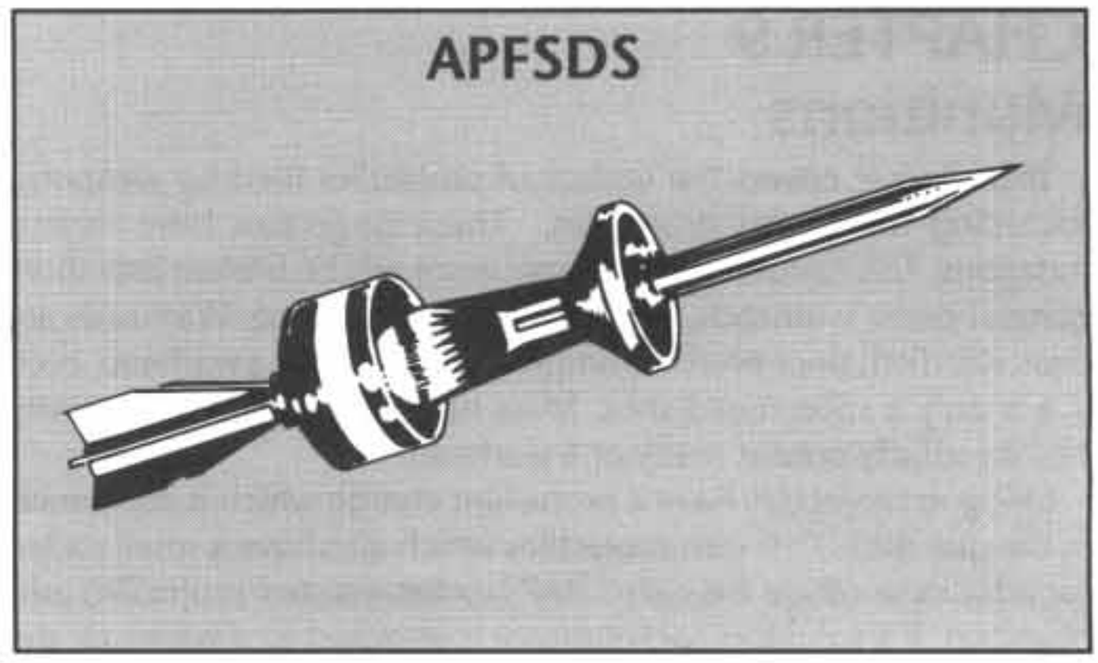
For example, the German World War II 50L60 antitank gun, found on field carriages and in the turret of Panzer IIIs, could penetrate about six centimeters of armor (**Traveller** armor value of 12) at medium range (1000 meters). It had a muzzle energy of 1.63 Mj. Given a projectile diameter of 50mm, this gives it a frontal area of about 20 square centimeters, or an energy density over its front of roughly 80 kilojoules.

By contrast, the German 88L71 gun, found on field carriages and as the turret gun of the massive Tiger II, could penetrate about 19 centimeters of armor (**Traveller** armor value of 38). It had a muzzle energy of about 4.5 Mj, a front cross-sectional area of 60 square centimeters, and an energy density over its front of roughly 75 kilojoules.



Notice that the 88L71's round penetrates almost three times as much armor but has about the same (actually slightly lower) energy density across the front than does the 50L60. Notice also that in both cases, the rounds penetrate about four centimeters of armor (8 levels of **Traveller** hard steel armor) per megajoule, illustrating the overwhelming importance of gross muzzle energy.

There are some limits to the penetration ability of a solid shot, however, and those limits center around the ability of the shot to withstand the impact with the armor. Beyond a certain velocity, solid steel shot will simply shatter against an armored plate. Early naval designers noticed this effect, and found it particularly prevalent against face-hardened armored plates. To deal with the problem, hard steel caps were fitted over the nose of the shot, and this type of ammunition (APC, for Armor Piercing Capped) is the type most often found at tech level 5. Since the best penetrating caps were rounded or blunt, a second pointed cap, to improve the ballistics of the shot, was often fitted as well, producing APCBC (Armor Piercing Capped, Ballistic Capped) ammunition.These are not treated as separate ammunition types in these rules, as they are really just minor improvements on the same basic round—a solid steel full-caliber penetrator.



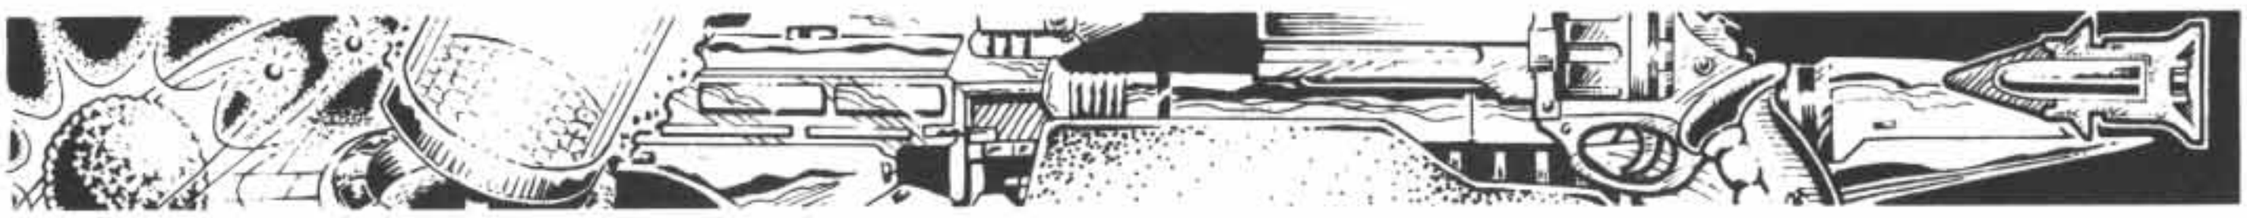
The next step forward was to concentrate the muzzle energy of the round over a smaller surface. This was accomplished by embedding a subcaliber penetrator in a lightweight outer shell. The lower weight of the round usually meant that it had higher muzzle velocity (gaining back its original muzzle energy as it traded mass for velocity) and so these rounds are usually called HVAP (for High Velocity Armor Piercing). A conventional steel penetrator would not stand up to this greater energy density, and so tougher materials had to be used, usually tungsten at tech level 5, where this ammunition appears. Difficulties in machining tungsten at that tech level make the round difficult to mass-produce, and so it was usually issued in limited numbers as a back-up round in case the weapon encountered a particularly well-armored opponent. The disadvantage of this round, aside from that mentioned above, was that its full-caliber ballistic cross-section gave it a high drag relative to its mass, and so it tended to decelerate more quickly than did a conventional round. Thus its penetration, while higher at first, declined quickly.

At almost the same time, gun designers began experimenting with the discarding sabot mentioned earlier. The advantage of this approach was that when the lightweight sabot was discarded, the round no longer suffered drag from it and so did not suffer the sharp fall-off in velocity. The disadvantage was that early APDS rounds tended to be unstable in flight and inaccurate, effectively negating the advantage of the round. For this reason, we ignore sabot rounds until tech level 6, where the technology was sufficiently perfected to allow accurate long-range fire. As with the HVAP round, the penetrator of a sabot round had to be made of a very tough metal, such as tungsten, or it would break up on impact with enemy armor.

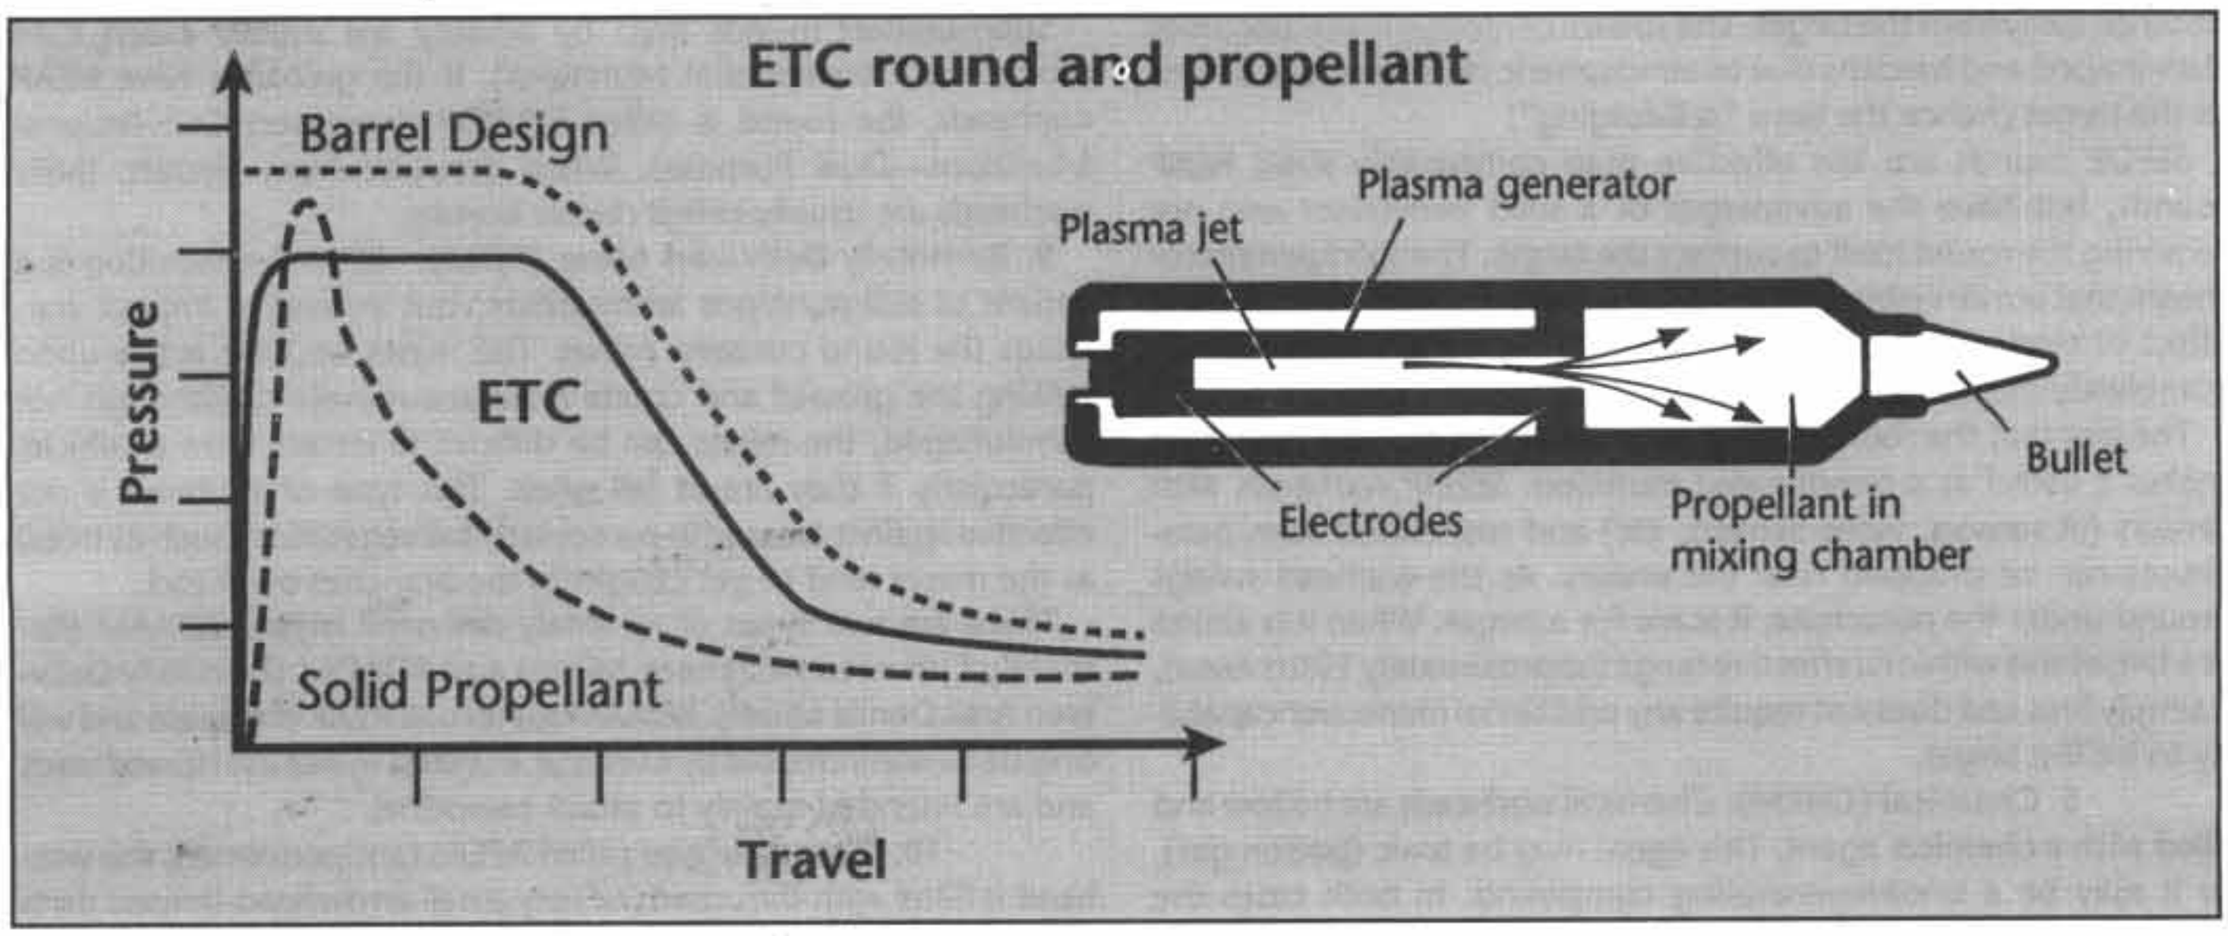
As propellant and metallurgy allow higher pressure levels in the gun tube, it becomes possible to force a round out of the gun at higher velocities. Some of this energy is used, however, in forcing the round through the rifling grooves (called lands) in the barrel. These grooves impart spin to stabilize the round, but limit the speed of the round. Forcing a round out the barrel too fast will simply strip the outer band from the round and push it out the barrel with no spin at all, in which case it will tumble end-over-end and quickly veer off course and decelerate. This is a function not only of velocity but also of the resistance the round has to spinning, based usually on its mass.

The solution is to dispense with rifling altogether and use fins to stabilize the round, hence the APFSDS (Armor Piercing Fin Stabilized Discarding Sabot) ammunition of tech level 7. Some early rounds at this tech level, in order to use existing rifled guns, used an ingenious hybrid system where the penetrator itself did not spin but the sabot,

mounted on a free-spinning race around the penetrator, did. Since only the lightweight sabot spun, little energy was used forcing it to do so, and its low resistance to spin meant that rounds could be forced out of the tube at very high velocities.



Smoothbore guns are so efficient that they enabled gunners to approach the practical limit on muzzle velocities of an explosively propelled gun, that being the velocity at which the gas expands from the explosion of the propellant. Obviously, a round cannot be pushed faster than the rate of gas expansion in the explosion, no matter how powerful the explosion, and the effective upper limit on velocity from this sort of propellant is 2000 meters per second. Contemporary smoothbore tank guns all throw their APFSDS rounds at about 1700 meters per second. (By contrast, hardly any World War II guns exceeded 1000 meters per second in muzzle velocity.)



The next step was to make the penetrator more massive, but hopefully without increasing its frontal area. This was accomplished by using not only tougher metals, but heavier ones, the first being depleted uranium, producing the APFSDSDU (Armor Piercing Fin Stabilized Discarding Sabot Depleted Uranium) ammunition of tech level 8. The ammunition of the 120mm gun of the M1A1 is a good illustration of the performance possible with this approach. The depleted-uranium penetrator has a mass of a little over 6 kilograms (as opposed to the 4.5-kilogram tungsten penetrator of the Soviet 125mm gun). Its muzzle velocity of 1675 meters per second gives it a muzzle energy of slightly more than 9 megajoules. By comparison, the German 128L55 gun mounted on the Hunting Tiger of World War II threw a 28-kilogram penetrator at 930 meters per second for a whopping 12 megajoules of muzzle energy. But while the German full-caliber capped steel round would penetrate 24 centimeters of armor (2 centimeters, or 4 armor levels, per megajoule), the M1A1's round will penetrate 65 centimeters (7 centimeters, or 14 armor levels, per megajoule).

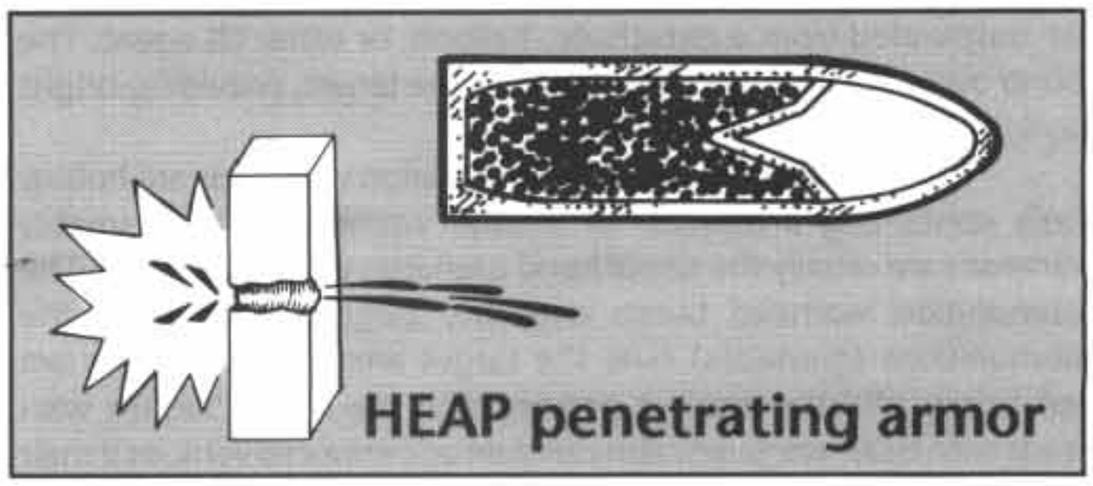
Notice that even as early as World War II (tech level 5), it was possible to mount a gun on a mobile chassis capable of generating over 10 megajoules of muzzle energy.

Having reached the ballistic limits of this type of weapon, remaining improvements come from tougher and more massive subcaliber penetrators, made from crystaliron (tech level 10), superdense (tech level 12), bonded superdense (tech level 14), and bonded coherent superdense (tech level 17).

But while the limits of explosively driven projectiles had been reached, there was still an additional step available to wring the last ounce (or gram) of performance from conventional guns, that being electrothermal propulsion or, in its most effective form, electrothermal-chemical (ETC).

An ETC round consists of a projectile exactly like that fired by a conventional powder charge and a casing behind it. This casing consists of two parts, a fuel supply and a combustion chamber. The fuel can consist of any fluid, even water, although chemically energetic working fluids work best (the difference between basic electrothermal—ET—weapons and ETC is that ETC harnesses and enhances the chemical energy of the working fluid, rather than using an inert working fluid). A powerful electric current converts the fuel in the combustion chamber to a plasma state, which escapes out the front of the casing and propels the projectile down the barrel. How is this different from a conventional round and what makes it more efficient?

Conventional barrels are designed to withstand the high pressures created by firing the explosive that propels the round out of the gun. However, a conventional explosive propellant produces a dramatic pressure spike at the breach end of the barrel, which falls off dramatically as the projectile moves down the barrel (as the volume of space behind it in the barrel increases). This means that even though most guns have reinforced breaches and thinner barrels near the muzzles, they are still capable of withstanding much more pressure toward the end of the barrel than they are called on to withstand.



In the case of ETC, however, the fuel is not converted to plasma all at once. The initial conversion creates pressure behind the projectile similar to that found in a conventional weapon, but as the projectile moves down the barrel, the casing continues to convert fuel to plasma, maintaining the same pressure in the barrel. Electrothermal-chemical propulsion techniques allow effective doubling of muzzle energy without any increase in weight of a gun (although some additional recoil compensation is necessary). ETC ammunition is being test-fired as this is written, with some extraordinary results, and will be widely available at tech level 9.

Beyond ETC and certain dense, tough metals for penetrators, the next major step forward will be electromagnetic propulsion. But as that constitutes an entirely different class of weapon, it is discussed separately.

3. High Explosive Armor Piercing (HEAP): The disadvantage of a high-velocity solid penetrator is that it relies almost exclusively on muzzle energy to pierce armor, and high muzzle energies require massive gun systems, much more massive than can be carried by an infantryman (who usually has his hands full with his personal weapon). One answer was found in the shaped charge round, also called a hollow charge round, which relies on the energy generated by an exploding shell rather than the muzzle energy of the projectile.

A shaped charge shell has an explosive charge with a hollow cavity recessed into the front of it (hence the "hollow charge" name). The hollow cavity is shaped like an inverted cone (hence the "shaped charge" name) and lined with metal. When the round hits its target, the charge detonates and turns the metal conical liner of the charge into a stream of molten metal. The shape of the charge tends to focus the molten metal into a narrow high-speed jet directly forward. This jet of gas and molten metal is what actually penetrates the armor.

For years it was widely thought that the molten jet burned through the armor, and so these shaped charges were also often called "thermal" penetrators. Actually, the temperatures generated by the explosion, while very high, are not high enough to melt through the armor as quickly as the jet actually penetrates it. Instead, the jet penetrates by kinetic energy, the same way that a solid penetrator does. That is, if you calculate the mass of the molten metal jet and its velocity, you can determine its impact energy in the same way that we calculated muzzle energy above and determine its armor penetration. (The mechanism used to calculate its game penetration is somewhat easier than that, however.)

4. Self-Forging Penetrator (SEFOP): A SEFOP round is a cross between a KEAP and HEAP round. Like the HEAP round, the warhead gains its penetrating energy from the force of an explosion. The penetrator created by the shaped charge explosion, however, is a much more massive stream of metal, and the charge fires a farther

distance away from the target. The stream of molten metal becomes dart-shaped and hardens due to atmospheric resistance as it travels to the target (hence the term "self-forging")

SEFOP rounds are less effective than comparably sized HEAP rounds, but have the advantages of a solid penetrator and not requiring the round itself to contact the target. The solid penetrator means that armor systems treat SEFOP as a KEAP round (reducing the effect of electrostatic armor and making explosive reactive armor completely ineffective against it).

The fact that the round itself does not have to contact the target makes it useful as a remote-area munition. SEFOP warheads with sensors (IR sensors, video sensors, etc) and suspended from parachutes can be dropped near the enemy. As the warhead swings around under the parachute, it scans for a target. When it is aimed at a target and within its effective range (approximately 100 meters), it simply fires and does not require any additional maneuver capability to hit the target.

5. Chemical (CHEM): Chemical warheads are hollow and filled with a chemical agent. This agent may be toxic (poison gas), or it may be a smoke-generating compound. In both cases the characteristics of the warhead itself are identical—only the effect of the agent differs.

Most chemical rounds are base-ejection rounds. This means that the agent is released through the base of the round, either after it hits or while it is still in flight, depending on which is the most effective means of delivering the agent.

6. White Phosphorus/Incendiary Smoke (WP/IS): White phosphorus burns at very high temperatures and produces large quantities of thick, white smoke. As a result, these rounds are sometimes called WP (White Phosphorus), or "Willy Pete," and sometimes called IS (Incendiary Smoke). The round is excellent for building a quick smoke screen. The heat of the round also makes it difficult for thermal or infra-red vision devices to see past the impact point of the shell. Finally, white phosphorus also has considerable anti-personnel capabilities.

White phosphorus rounds are difficult for many vehicles to use, as ammunition is usually stored horizontally in vehicles. (It is easier for a human loader to remove rounds stored horizontally than vertically.) White phosphorus rounds must be stored vertically, however. If the round is stored horizontally, the white phosphorus filler will settle to one side of the warhead and throw it out of balance, ruining its accuracy.

7. Illumination (ILLUM): Illumination rounds contain a brightly burning flare, usually made in part from magnesium powder, suspended from a parachute, balloon, or other lift agent. The round burns brightly after it bursts over the target, providing bright daylight illumination of the battlefield.

8. Submunition (SM): Submunition warheads are hollow shells containing a number of smaller warheads. These smaller warheads are usually the size of hand grenades or slightly larger. The submunition warhead bursts over the target and scatters the submunitions (grenades) over the target area. Submunitions are particularly effective against personnel in the open. Variant warheads with HEAP warheads also can damage armored vehicles if their overhead armor is fairly thin. Submunitions are seldom effective against troops in hardened shelters with good overhead protection. Incendiary warheads allow a large area to be ignited quickly and are often used in aerial attacks on cities.

Submunition rounds fired by artillery are usually called ICM (Improved Conventional Munitions). If the grenades have HEAP warheads, the round is called ICM-DP (Improved Conventional Munitions—Dual Purpose). When dropped from aircraft, these warheads are usually called cluster bombs.

9. Remotely Delivered Mine (RDM): RDM Ammunition is a variant of submunitions ammunition, but instead of impact warheads the round contains mines. The mines become active upon striking the ground and create a surface minefield. Although not camouflaged, the mines can be difficult to detect from a vehicle, particularly if they are in tall grass. This type of warhead is not effective against areas with particularly tall vegetation (such as trees) as the mines tend to get caught in the branches overhead.

There are two types of remotely delivered mines: RDAAM (Remotely Delivered Antiarmor Mines) and RDADM (Remotely Delivered Area Denial Mines). RDAAM mines use HEAP warheads and will only detonate if crossed by a vehicle. RDADM mines use HE warheads and are intended mainly to attack personnel.

10. Flechette: Also called APERS (antipersonnel), this warhead is filled with thousands of very small arrowhead-shaped darts (flechettes). The round also has a timing fuse and a bursting charge. When fired at the enemy, the round travels part of the distance to the target and then explodes, releasing the flechettes to continue along the ballistic path of the round. The round is murderous against unprotected or lightly protected personnel, but has little penetration against armor.

11. Chaff: A chaff warhead is filled with lightweight strips of radar-reflective material designed to reduce the effectiveness of enemy radar and active EMS sensors.

B. Warhead Tech Level

The tech level of the warhead influences its performance in a variety of ways shown in later steps of the design process. In addition, certain warheads are not available until higher tech levels.

TL	*Warhead*
4	Most warheads
5	HEAP
5	WP
6	Flechette
6	Chaff
7	Submunition
7	RDM
8	SEFOP

C. Warhead Diameter

The warhead diameter is the bore of the gun (in centimeters) from which the round is fired, if it is a round of artillery ammunition. Bomb, rocket, and missile warheads may be of any diameter desired.

HE, KEAP, and HEAP warheads may be any size from 2cm up. Submunition and RDM warheads must be at least 10cm in diameter. All other warheads must be at least 4cm in diameter.

Submunitions are additionally categorized as light, medium, or heavy, depending on their warhead diameter. Light submunition warheads are less than 15cm in diameter. Medium submunition warheads are less than 20cm in diameter. Heavy submunition warheads are 20cm or more in diameter.

Aerial bombs are usually designated by mass rather than diameter, but since the rest of the design sequence relies on warhead diameter, select a warhead size that corresponds to the desired mass.

D. Damage Value

Damage value is a measure of the force generated at the point of impact by the warhead. Usually this is a measure of the explosive force of the round, and is called its concussion rating. Non-exploding rounds do damage by energy of impact. Damage is calculated differently for various types of warheads.

1. High Explosive: HE rounds do damage by the concussion of the explosion of their bursting charges. The concussion value of the charge is calculated using the following formula:

$$C = Tm \times D^2$$

(Concussion equals tech modifier times diameter squared)

C: Concussion value

D: Warhead diameter in centimeters

Tm: Tech level modifier, as shown on the following chart:

TL	*Tm*
4	.075
5	.1
6	.125
7	.15
8	.175
9	.2
10+	.25

2. KEAP: Kinetic energy warheads have a damage value equal to their diameter in centimeters multiplied by 2.2. This is a constant value for use only for direct hits on personnel. It is never used vs. vehicle targets.

3. HEAP: HEAP warheads use the same formula and table as for an HE round of the same diameter, but multiply the final result by 0.66.

4. SEFOP: SEFOP warheads use the same formula and table as for an HE round of the same diameter, but multiply the final result by 0.5.

5. CHEM: All chemical warheads less than 10cm in diameter have a concussion value of 2, while all warheads 10cm or more in diameter have a concussion value of 3.

6. WP: All white phosphorus warheads less than 10cm in diameter have a concussion value of 2, while all warheads 10cm or more in diameter have a concussion value of 3.

7. Flechette: Each flechette does personnel damage equal to fragments by burst area (2D6 within primary radius, 1D6 in secondary).

8. Others: Other warhead types have no damage value.

E. Burst

Burst radius defines the area covered by the primary effects of a bursting warhead. This can be the area covered by potentially lethal fragments, chemical agents, illumination, and so on, depending on warhead type.

The formulas below give exact burst radii. To convert to the standard **Traveller** burst area figures resolved to the 10-meter grid (see page 284, basic rules), round to the nearest 10-meter increment. For example, 7 meters rounds to 5, 12 rounds to 15, 30 to 35.

1. High Explosive: The burst radius of an HE warhead is the primary burst area covered by fragments. The burst radius in meters is the square root of the warhead's concussion value multiplied by the munition multiplier, as shown below.

Munition	*Multiplier*
Gun, Grenade	7
Mortar, Rocket, Aerial Bomb	10

2. KEAP: Kinetic energy penetrators do not explode and so have no burst radius.

3. HEAP: The burst radius of a HEAP warhead is calculated with the formula for HE warheads, but the result is multiplied by 0.5.

4. SEFOP: The burst radius in meters of a SEFOP warhead is calculated using the same formula as for an HE warhead.

5. CHEM: The burst radius in meters of a chemical warhead is equal to the warhead diameter squared and divided by 8.

6. White Phosphorus: The burst radius in meters of a white-phosphorus warhead smaller than 10cm in diameter is equal to the warhead diameter multiplied by 2. The burst radius in meters of a warhead 10cm or greater in diameter is equal to the warhead diameter multiplied by 3.

7. ILLUM: The burst radius in meters of an ILLUM warhead is equal to the warhead diameter in centimeters multiplied by a tech level modifier and the result squared.

$$B = (D \times Tm)^2$$

D: Warhead diameter in centimeters

Tm: Tech level modifier, as shown below.

TL	*Tm*
4-5	2.5
6-7	3
8-9	3.5
10+	4

8. Submunition: The burst radius in meters of a submunition warhead is equal to the warhead diameter in centimeters squared and divided by 4.

At tech level 9 and above, it is possible to reduce the number of submunitions and add homing systems to the individual bomblets. Submunition rounds with homing bomblets have only half the burst radius of a regular submunition round. (Burst radius in meters is equal to the warhead diameter squared and divided by 8). However, the designer specifies whether the homing sensors are set for vehicles or personnel. Add 2 to the chances of a direct hit against that target type from a homing submunition. (Personnel would be hit on a roll of 1-3 instead of just 1. Vehicles would be hit on a roll of 1-7 instead of 1-5.)

9. RDM: The burst radius in meters of a remotely delivered mine warhead is equal to the warhead diameter squared and divided by 2.

10. Flechette: Unlike other rounds, flechette rounds have an elongated burst area, since the flechettes keep moving along the ballistic path of the round after it explodes. The primary burst area is the area immediately after the point at which the round explodes, while the secondary burst area is the area after that.

Because the flechettes retain the original velocity of the carrier round after it explodes, the burst area (also called danger space) of the flechettes is based on the velocity of the warhead. The calculated burst area is the length of the burst area. The width of the burst area is one-quarter of its length.

Flechette burst radius for artillery shells is calculated using the following formula:

$$B = .2R$$

B: Burst radius in meters
R: Short range in meters

Flechette burst area for rocket and missile warheads is calculated using the following formula:

$$B = .05V$$

B: Burst radius in meters
V: Average velocity in kilometers per hour

11. Chaff: The burst radius in meters of a chaff warhead is equal to the warhead diameter multiplied by a tech level modifier and the result squared.

$$B = (D \times Tm)^2$$

D: Warhead diameter in centimeters
Tm: Tech level modifier, as shown below:

TL	*Tm*
4-5	2.5
6-7	3
8-9	3.5
10+	4

Any enemy radar attempting to detect a target through a chaff cloud does so at one level of difficulty higher. For each tech level the chaff warhead is above the sensor, add one more to difficulty.

Chaff from a chaff round remains airborne in effective quantities for 1D6 combat turns.

F. Penetration

Penetration represents the ability of a warhead to punch through armor and cause damage to the systems protected by that armor. The specific penetration capability of the weapon depends on the type of ammunition being fired.

Penetration capabilities in **Traveller** are quantified in two ways: *penetration value* and *penetration rating.*

Penetration value is the total penetrative capability of a weapon or munition. It is most often used in vehicle combat, and in rating large weapons.

Penetration rating describes the relationship between the weapon's damage value and its penetration value. Penetration value = Damage value + Penetration rating. Likewise, Damage value = Penetration value × Penetration rating.

1. High Explosive: HE (High Explosive) rounds are the standard ammunition of most field guns from tech level 4 on. As they explode on contact and are designed to spread fragments in every direction, they are not effective armor penetrators, but can do some damage.

Penetration of HE rounds is a function of bore size. Multiply the bore size (in centimeters) by 1.5 and subtract 7 to determine the penetration value of the round. All HE rounds have a constant penetration value and so should have the letter "C" written after the value. Rounds with a penetration value of less than 0 are shown as "Nil." Rounds with a penetration value of 0 have that listed as their penetration value (meaning that the final penetration is the base 2D6 roll without any addition).

2. KEAP: KEAP (Kinetic Energy Armor Piercing) includes all solid penetrators which rely on muzzle energy to pierce hostile armor. Penetration value is a function of range, muzzle energy, and the type of ammunition fired.

The base penetration value of solid shot (tech level 4) ammunition at medium range is based solely on muzzle energy (in megajoules) of the gun, as shown below:

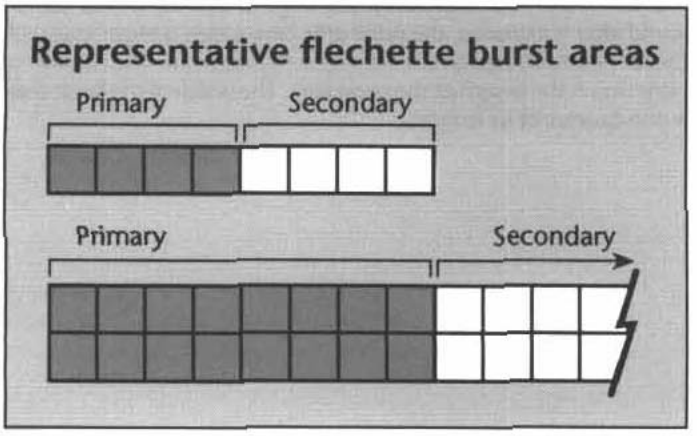
If Mj = 12+, then PV = Mj×4
If Mj < 12, then PV = Mj×5 (but never higher than 48)
If Mj < 9, then PV = Mj×6 (but never higher than 45)
If Mj < 7, then PV = Mj×7 (but never higher than 43)
If Mj < 5, then PV = Mj×8 (but P never higher than 35)
If Mj <1.5, then PV = Mj×10 (but P never higher than 12)
If Mj < 1, then PV = Mj×12 (but P never higher than 10)
If Mj < 0.5, then PV = Mj×16 (but never higher than 6)
If Mj < 0.3, then PV = Mj×22 (but never higher than 5)

For example, a gun has a muzzle energy of 4.6 Mj. Since this is less than 5 but not less than 1.5 Mj, the gun has a penetration value equal to Mj×8, or 36.8, rounded up to 37, but then reduced to 35 (the maximum PV for weapons with a muzzle energy less than 5 Mj).

At higher tech levels, specialized ammunition allows increased penetration. Multiply the penetration of the round as calculated above by the ammunition multiplier, as shown below:

Special Ammunition

TL	*Ammo*	*Multiplier*
5	HVAP	1.3
6	APDS	1.7
7	APFSDS	2.4
8	APFSDSDU	3
10	APFSDSCI	4.5
12	APFSDSSD	5
14	APFSDSBSD	6
17	APFSDSBCS	7



HVAP: High Velocity Armor Piercing
APDS: Armor Piercing Discarding Sabot
APFSDS: Armor Piercing Fin Stabilized Discarding Sabot
DU: Depleted Uranium
CI: Crystaliron
SD: Superdense
BSD: Bonded Superdense
BCS: Bonded Coherent Superdense

Once the medium-range penetration is known, penetration values at the other range bands can be calculated.

At short range, add 15% of the penetration value or a flat value of 10, whichever is less.

At long range, subtract 15% of the penetration value, or a flat value of 10, whichever is less.

At extreme range, subtract 45% of penetration, or a flat value of 30, whichever is less.

3. HEAP: HEAP rounds are available at TL 5 and higher. Penetration of HEAP rounds is a function of bore size and tech level. Multiply the bore size (in centimeters) by the tech level multiplier shown below and subtract 7 from the result to determine the penetration value of the round. All HEAP rounds have a constant penetration and so should have the letter "C" written after the value. Rounds with a penetration value of less than 0 are shown as "Nil." Rounds with a penetration of 0 have that as penetration (meaning that the final penetration is the base 2D6 roll without any addition).

TL	*Multiplier*
5	4
6	6
7	8
8	10
9+	12

4. SEFOP: Self-forging penetrator warheads are available at tech level 8 and above. Penetration is calculated the same as for HEAP warheads, and using the same table of tech level multipliers.

5. Submunition: Penetration of grenades.

6. Flechette: The flechettes contained in the warhead have the same penetration as normal fragments (1 in the primary radius, Nil in the secondary), but the flechette round itself, should it hit an armored surface, has a penetration of Nil.

7. Other: All other warheads have a penetration of Nil.

G. Mass

The table below lists the mass of most warheads. Values between those shown on the table can be obtained by interpolation.

Diameter (cm)	*Mass (kg)*
2	.2
3	.4
4	.8
5	1.5
6	3
7	6
8	12
9	17
10	21
11	25
12	30
13	35
14	43
15	50
16	60
17	72
18	85
19	100
20	115
21	140
22	160
23	185
24	215
25	250
30	500
35	1000
40	2500
45	5000
50	10,000

1. KEAP: Regular KEAP warheads (solid shot) are twice the mass shown on the table above. HVAP rounds are 1.5 times the mass shown on the table above. All other KEAP rounds (APDS, APFSDS, etc.) have the mass shown on the table.

2. Special Rounds: The above values are for aerial bombs and artillery shells. Alternative munitions have the following masses.

Type	*Mass*
Hand and Low-Velocity Propelled Grenade*	×0.3
Medium-Velocity Propelled Grenade*	×0.4
Rocket, Missile, Light Recoilless Rifle*	×0.4
Rifle and High-Velocity Propelled Grenade*	×0.5
RAM Grenade*	×0.6
Heavy Recoilless Rifle*	×0.7
Mortar	×0.8

*Note that in the case of propelled grenades and recoilless rifle rounds, the above masses are for the entire round including propellant.

H. Volume

The volume of a warhead in cubic meters for purposes of storage is equal to the diameter of the warhead in centimeters multiplied by 0.000008.

I. Price

The base price for ammunition in credits is equal to its mass multiplied by its ammunition type modifier, as shown below.

Type	*Modifier*
HE	10
KEAP (AP)	5
HVAP	15
APDS	15
APFSDS	15
APFSDSDU	30
APFSDSCI	35
APFSDSSD	40
APFSDSBSD	45
APFSDSBCS	50
HEAP	15
SEFOP	20
CHEM	10
WP/IS	20
ILLUM	10
SM	60
SM (Homing)	100
RDM	100
Flechette	50
Chaff	20

RAM (rocket-assisted multipurpose) grenades cost 10 times the normal warhead price.

Recoilless rifle ammunition costs 1.5 times the normal warhead price.

Note that in the case of propelled grenades and recoilless rifle rounds, the above prices are for the entire round including propellant.

SPECIAL WARHEADS

Most munitions consist of standard warheads used in a variety of roles, either fired, propelled, or dropped. The following warheads are more specialized with limited uses or limited acceptable delivery means.

1. Hand Grenades: Hand grenades are thrown weapons, with the distance thrown being determined by the mass of the grenade. (See the thrown weapon rules on page 282 of the basic game for an explanation of this procedure.)

Hand grenades can use HE, HEAP, CHEM, WP, or ILLUM warheads. They consist exclusively of a warhead and a detonator (either a timer or a contact fuse), but the mass and cost of the detonator are subsumed in the values or the warhead itself. Most hand grenades use a warhead of about 4.5cm diameter, which results in a grenade massing 0.46 kilograms, costing Cr4.6, and with, at tech level 7, damage values of C:3, B:12 (assuming HE).

Two special types of warheads are available for grenades: concussion and thermite.

Concussion: These grenades have more explosive filler than HE grenades and are enclosed in a pressed paper or plastic container designed to be completely consumed by the explosion. The result is a more powerful blast but no lethal fragments.

To calculate the concussion value of concussion grenade, multiply the normal HE concussion value of a grenade of that size by 1.6. Concussion grenades have no burst radius and have the same mass and cost of HE grenades.

Thermite: These grenades are extremely hot incendiary grenades useful for destroying large machinery. (Dropped down the barrel of cannon, the thermite grenade will burn through the breach block.) Thermite grenades have the same concussion as a WP grenade, but only one-third of the burst radius. Thermite grenades produce no significant mount of smoke. Thermite grenades cost half as much as WP grenades of the same size, but are otherwise identical.

2. Rifle Grenades: Rifle grenades are designed to be fired from standard military slug-firing rifles. The grenade itself has no propellant and is instead projected by the force of the bullet fired from the rifle. As a result, rifle grenades tend to be fairly light, and they are very inaccurate.

Range: Rifle grenades may only be fired in indirect fire. The indirect fire range of a rifle grenade is determined using the following formula:

$$R = (D+M)Tm$$

R = Indirect fire range in meters
D = Damage value of the rifle or carbine firing the grenade
M = Mass in kilograms of the grenade
Tm = Tech level modifier, as shown below:

TL	*Tm*
5-6	35
7-8	65
9+	95

3. RAM Grenades: Rocket-assisted multipurpose (RAM) grenades are available at tech level 8 and above as rifle grenades. These grenades may be fired in either direct or indirect fire. Since these are rocket-propelled grenades, their range does not vary with damage value of the bullet fired from the rifle. Masses and prices are given in the design sequence above. Range is shown below:

TL	*Short Range*	*Indirect Fire Range*
8	30	500
9	40	550
10	50	1500
11	60	2000

4. Mines: Mines are simply emplaced warheads. Any warhead type may be used as a mine. The mine consists of the warhead and a fuse. Fuses have negligible volume and mass, and cost as shown on the following table:

TL	*Fuse*	*Cr*
4	Contact	10
6	Radio	20
8	Proximity	100

Mines mass half as much as a standard warhead of the chosen diameter and use the same cost multipliers as for a conventional warhead. Nonmetallic mines cost twice as much for the warhead and 10 times as much for the trigger.

5. Napalm: Napalm is a mixture of hydrocarbon distillates, thickeners, and other components designed to aid combustion (such as powdered aluminum, charcoal, white phosphorus, etc.).

Napalm is available at tech level 5 and up. Because it is most effective when spread over a wide area, it is not generally used in artillery or rocket warheads or streamlined gravity bombs designed to impact the ground at a steep angle. Instead, it is used in unstreamlined cannisters designed to tumble when released by aircraft at low altitude. These cannisters break open when they hit the ground and scatter burning fuel along the flight path of the aircraft.

Aerial napalm cannisters are relatively inaccurate weapons and are effective against personnel in the open and soft vehicles. Their effect is increased greatly by the presence of dry foliage, and reduced almost to nil by wet weather or ground conditions.

Napalm cannisters mass 350 kilograms each. They have no concussion value and a burst area 20 meters wide and 100 meters long. (There is no secondary burst area.) If hit by fragments, consult the burn damage rules (TNE, page 286).

6. Nuclear Warheads: Because of the tremendous damage already caused by the Final War, nuclear warheads are looked upon with a particularly intense revulsion. That does not keep occasionally irresponsible leaders from using, or threatening to use, these weapons of indiscriminate mass destruction.

Yield	*Crater*	*Induced*	*Destruction*	*Primary*	*Secondary*	*Size*
.1	25	30	30/50	100/150	200/300	17
.5	25	35	30/60	150/180	330/360	18
1	40	40	30/60	210/240	420/420	19
2	50	60	60/90	300/300	540/540	20
5	50	80	150/120	480/420	660/600	21
10	60	90	180/120	540/480	720/660	22
20	60	100	300/240	540/480	900/720	23
50	70	120	420/300	750/600	1200/900	24
100	100	140	480/420	750/600	1260/1080	25

Yield: Warhead size in kilotons.

Crater: Diameter of crater in meters. Only ground strikes produce craters. Ground units may not enter the crater of a nuclear blast until it has been decontaminated.

Induced: Radius of induced radiation in meters. For 30 minutes after the detonation of the the warhead, the radius of induced radiation is equal to the secondary blast radius. After that, it shrinks to the listed induced radiation radius listed above. Everything inside this radius is contaminated with radiation. Unprotected personnel must leave the induced radiation area within 15 minutes or begin suffering progressively greater health effects. Personnel in sealed environment suits, sealed armor, or vehicles with hostile environment capability ignore induced radiation.

Destruction: The destruction radius in meters. The first number is the destruction radius from a ground strike, the second is the area from an air burst.

All targets in the destruction radius are destroyed, and any flammable material ignites and burns.

Primary: The primary blast radius in meters. The first number is the blast area from a ground strike, the second is the area from an air burst.

All targets in the primary blast radius are treated as if within the primary blast radius of a conventional explosion and suffer fragmentation attacks accordingly. All targets are also attacked with a concussion value of 10. (Note that this does not affect enclosed vehicles.) All trees and frame buildings in the primary blast radius are blown down.

Secondary: The secondary blast radius in meters. The first number is the blast radius from a ground strike, the second is the radius from an air burst.

All targets in the secondary blast radius are treated as if within the secondary blast radius of a conventional explosion and suffer fragmentation attacks accordingly.

Size: Minimum warhead diameter in centimeters for this yield. Nuclear warheads are first available at tech level 6. At later tech levels, the minimum warhead size is reduced as shown on the following chart:

TL	*Size*
7	–2 cm
8	–4 cm
9	–6 cm
11	–7 cm
13	–8 cm
15	–9 cm
17	–10 cm
19	–11 cm

Price: The price of the warhead in millions of credits is equal to its yield multiplied by 0.01.

Storage: A nuclear warhead must be stored in a shielded container or a damper box. A shielded container takes up four times the volume of the warhead, masses three times the mass of the warhead, and costs MCr0.01 per cubic meter of volume.

7. Collapsing Nuclear Warheads: Collapsing warheads are much smaller than standard nuclear warheads. This is made possible by using very unstable fissionable materials, such as californium, and by omitting the reliable but bulky detonation system found in standard rounds. Instead, these warheads rely on impact with vehicle or structural armor to collapse the hollow round quickly into a critical mass, resulting in unreliable performance.

Collapsing rounds may only be fired from CPR or mass driver guns with a short range of 400 meters or more. They may only be fired at hard targets, such as concrete buildings, armored vehicles, starships, etc.

If a collapsing round hits, it successfully detonates only on a die roll of 7 or less (on a D20). On any other roll, the round was a dud.

The information on collapsing rounds is noted in the following table. It is read exactly the same as the main nuclear warhead table above, except as noted specifically below.

Yield	*Crater*	*Induced*	*Destruction*	*Primary*	*Secondary*	*Size*
.001	10	5	20/30	25/60	50/120	2
.002	10	10	20/35	30/70	60/140	3
.005	15	10	20/35	40/75	80/150	3.5
.010	15	15	25/40	50/95	100/190	4
.050	20	20	25/45	75/120	150/240	6
.100	25	30	30/50	100/150	200/300	7

TL: Collapsing nuclear rounds are available at tech level 14 and higher.

Size: Minimum warhead diameter in centimeters for this yield.

Price: The price of the warhead in millions of credits is equal to its yield multiplied by 1.

Storage: Because of their short useful half-life, collapsing rounds *must* be carried in damper boxes.

8. Nuclear-Pumped X-Ray Lasers: The one area where nuclear warheads are used fairly regularly is on space-based X-ray laser missiles. Each of these warheads consists of a nuclear device, an array of X-ray lasing rods, a short-range tracker, a receiver for a 300,000-km laser communicator, and a small battery power pack. The missile operator maneuvers the warhead into range of the target (using whatever maneuver package the designer has chosen to include in the weapons system). The on-board tracker makes the final precision target corrections and the operator fires the warhead. The explosion of the warhead destroys the lasing rods, but not before pumping a tremendous burst of energy through them and toward the target.

All components of the nuclear X-ray laser warhead are included in a single package as shown on the following chart.

All nuclear X-ray pumped warheads roll 1D6 for hits on target when they detonate; each of these hits does damage equal to that listed in the "Dmg" column.

Range for space combat (in increments of 30,000 km) is given on the bottom line. By increasing size and price, longer range (to the right of the slash) may be acheived. Note that this is only possible in a campaign using the optional laser focusing technology field.

				Volume at Tech Level				
Yield	*MCr*	*Dmg*	*8*	*9-10*	*11-12*	*13-14*	*15-16*	*17+*
10	.6	1/8-25	.29	.195	.16	.132	.103	.08
20	.7	1/11-35	.32	.215	.18	.148	.113	.09
50	.8	1/14-43	.35	.235	.2	.168	.127	.10
100	.9	1/18-56	.39	.265	.22	.188	.147	.11
200	1.1	1/21-66	.51	.355	.28	.248	.167	.13
500	1.2	1/25-79	.71	.505	.4	.358	.247	.17
Range	—	—	0/0	0/0	0/0	0/1	0/1	0/2

Yield: Warhead yield in kilotons.

MCr: Price in millions of credits for the warhead package.

Dmg: Damage expressed in terms of laser penetration rating-damage value.

Volume: The listed values are the volumes in cubic meters of the complete warhead packages at each tech level.

Mass: Each warhead masses 1 tonne per cubic meter.

Range: Range in starship combat hexes/range bands. Range to the left of the slash is normal range, to the right is range available by doubling volume and multiplying price by 10. Range of 0 means fires into same hex only.

GUIDANCE

Warheads, whether they are powered or unpowered, may have guidance systems installed.

Maneuver: In order to have a guidance system installed, a warhead must be able to maneuver. In most cases, this will mean that it is powered by an engine of some kind. Unpowered warheads can have guidance packages installed however, which allow them to vary their projected target point by as much as 10% of the distance between the target and the launch point (or firing point). An unpowered warhead must have fins that enable it to maneuver, however. These fins are extremely light and do not add significantly to warhead mass. They do add Cr1 to the warhead price per kilogram of warhead mass.

Guidance: Guidance systems include command guidance, target designation, homing, and smart.

1. Command Guided: In this guidance system, the operator must pilot the warhead to the target. These guidance systems are distinguished by their operating system and their command link.

Operating system is a measure of how sophisticated the tracking software of the guidance system is. Manual operation means that the warhead must be maneuvered toward the target by the operator by observing both the target and warhead and mentally computing the necessary course changes. Semiautomatic guidance still requires the operator to track both the target and the missile, but flight controls are vastly improved and the warhead has superior flight characteristics, enabling it to fly at higher speeds and still be controlled. Automatic guidance means that the operator is only required to track the target, while the guidance system itself computes the corrections necessary to fly the warhead to it. Teleguidance allows the operator to "see" directly out the front of the warhead and thus eliminates the need for a continuous line of sight between the operator and the target. Instead, the operator simply flies toward the target until impact.

The characteristics of the various operating systems are shown on the table below.

TL	*Type*	*Mass*	*Cr*	*Speed (kph)*	*AGL*
5	Manual	1	40	300	–2
6	Semiauto	2	80	600	–1
7	Automatic	2	100	900	—
8	Teleguidance	2	100	1200	—

TL: Tech level of first availability.

Type: Operating system used.

Mass: Mass in kilograms of the controller in the warhead.

Cr: Price in credits of the controller in the warhead.

Speed: The highest allowed average speed. This value is used when calculating missile propellant and performance later.

AGL: Modification to the missile's final Agility rating (if mounted on a missile).

Volume: All operating systems have a volume of 1 liter per kilogram.

In addition to an operating system, a command guidance package must have a communication link between the operator's control unit and the controller in the warhead itself. For wire-guided missiles, there is no additional equipment to be installed as this equipment is subsumed under the other areas of the design, but radio and laser guidance does. The type of communication link also limits the maximum range of the missile. The table below summarizes the characteristics of various communication links.

TL	*Type*	*Mass*	*Cr*	*Range (km)*
5	Wire	—	—	2
6	Wire	—	—	4
7	Wire	—	—	6
5	Radio	2	40	*
6	Radio	1	40	*
7	Laser	1	70	10
8+	Laser	1	50	*

TL: Tech level of first availability.

Type: Comm link used.

Mass: Mass in kilograms of the comm link in the warhead.

Cr: Price in credits of the comm link in the warhead.

Range: The longest allowed range using the listed communication link.

* The range of radio-guided warheads and tech level 8+ laser-guided warheads is equal to the long range of the communicator installed in the control unit. Consult the Launchers chapter (page 147) for a discussion of the launcher control unit.

Volume: All comm links have a volume of 1 liter per kilogram.

2. Target Designated: This guidance system employs a seeker head in the warhead which enables it to home in on the reflected radiation of a designator, either a laser or a radar. The prices and masses of the seeker heads are shown on the table below.

TL	*Type*	*Mass*	*Cr*
6	Radar	2	1000
7	Radar	2	1000
8+	Radar	1	1000
7	Laser	1	500
8	Laser	1	500
10+	Laser	1	500

3. Homing: These guidance systems lock onto and home on certain well-defined levels of emissions of radiation. Infrared missiles home on high heat signatures. Anti-radiation missiles (ARM) home on radar or radio emissions. In both cases, improved versions have more sophisticated sensors capable of tracking at greater distances and at more difficult engagement angles.

TL	*Type*	*Mass*	*Cr*	*Range*	*AGL*
6	IR	1	500	10	–2
7	Improved IR	1	1000	15	–1
8	Advanced IR	1	1500	20	—
7	ARM	1	1000	12	–2
8	Improved ARM	1	2000	24	–1

TL: Tech level of first availability.
Type: IR = Infrared homing. ARM = Anti-radiation missile.
Mass: Mass in kilograms of the guidance system in the warhead. There is no control unit.
Cr: Price in credits of the guidance system in the warhead.
AGL: Modification to the missile's final Agility rating (if mounted on a missile).
Volume: All homing guidance systems have a volume of 1 liter per kilogram.

4. Smart Warheads: Smart warheads encompass two methods of guidance: target memory and target seeker. Both are true "fire-and-forget" weapons, but they are distinguished by what the operator is required to do prior to firing.

Target memory warheads have sensor units capable of distinguishing between unique target shapes. While still carried by the launch vehicle, the image generated by the sensor is projected onto the operator's video screen. When the sensor in the warhead acquires a target the operator considers suitable, the warhead is launched and the sensor, remembering the specific target acquired, will move to intercept it.

Seeker warheads have a pre-programmed set of target images that the sensor will recognize, and are simply launched into the general area of likely targets, after which they will seek out an appropriate target and attack it.

The characteristic of smart guidance systems are shown below:

TL	*Type*	*Mass*	*Cr*	*AGL*
7	Memory	3	10000	–1
8	Memory	2	5000	—
8-10	Seeker	1	1000	–2
11-13	Seeker	1	1000	—
14+	Seeker	1	1000	+2

TL: Tech level of first availability.
Type: Target memory or seeker.
Mass: Mass in kilograms of the guidance controller in the warhead.
Cr: Price in credits of the guidance controller in the warhead.
AGL: Modification to the missile's final Agility rating (if mounted on a missile).
Volume: All operating systems have a volume of 1 liter per kilogram.

In addition to a guidance system, a smart warhead must have a sensor which it uses to gather target information. The type of sensor used has no effect on the chance of the missile hitting, but does effect the conditions under which it can operate at all.

Visual sensors allow clear-weather daylight operation. IR sensors allow night operations along with some low-visibility operations (chemical smoke, fog, light rain, etc.). Imaging radar sensors allow operation in all light and atmospheric conditions (but is subject to jamming like all radars).

The characteristics of sensors are summarized on the table below.

TL	*Type*	*Mass*	*Cr*
7	Visual	1	200
7	IR	1	2000
8	Imaging Radar	1	10,000

TL: Tech level of first availability.
Type: Type of installed sensor.
Mass: Mass of the sensor added to the warhead.
Cr: Additional price to add the sensor to the warhead.
Vol: The volume of a sensor is 1 liter per kilogram.

5. Top Attack: Top attack may be added as an option to any guidance package from tech level 8 on, provided the warhead is either HEAP or SEFOP. Top attack means that the weapon's warhead is angled to fire perpendicular to the flight path of the munition, thus firing into the top of a vehicle as it passes over it. Top attack options are of no real use against aircraft, only vehicles which generally have weaker overhead armor than front armor.

Adding the top attack option doubles the warhead price, but has no other effect on the munition.

PROPELLANT

Virtually all warheads are propelled in one manner or another (with the notable exception of mines).

A. CPR Ammunition: CPR projectiles are propelled by the explosion of a propellant charge in the gun tube. This propellant charge is purchased separately from the warhead (although its mass is usually added to that of the warhead to make a complete round of ammunition).

Mass: The propellant required for CPR guns varies with the mass of the warhead and the length of the barrel. Propellant mass for CPR gun ammunition is calculated using the following formula:

Mp = .007MwBl

Mp: Mass (in kilograms) of propellant for the round.
Mw: Mass (in kilograms) of the warhead
Bl: Barrel length (in calibers) of the gun.

Propellants for mortars, propelled grenades, and recoilless rifles are included in the base mass of the warhead.

Rocket-assisted projectiles (RAP) are available from tech level 5 on. RAP projectiles require additional propellant mass equal to the warhead mass (regardless of barrel length). This is in addition to the normal propellant requirement of these weapons.

Base bleed (BB) propellant is available for CPR guns at tech level 7+. Base bleed charges do not add to the mass of propellant, but cost more.

Note: In both the RAP and BB rounds, the specialized "propellant" (in the RAP, rocket fuel, in the base bleed round, a combustible chemical which is burned in a generator at the base of the round—the resulting gas creates an overpressure and smooths the airflow around the round, thus increasing its range) is actually part of the warhead, but is calculated here for simplicity.

2. Price: The price of artillery propellant in credits is the mass of the propellant multiplied by 5. This price is doubled when calculating the price of base bleed and RAP propellant.

B. Atmospheric Rockets and Missiles: Rockets and missiles are powered by rocket engines which, unlike artillery shells, continue to propel the projectile after it has left the launcher. For purposes of propellant design, there is no difference between a rocket and a missile. The terms are usually used to distinguish between unguided (rocket) and guided (missile) rocket-propelled warheads.

Rockets and missiles generally use rockets, most commonly solid fuel rockets, but may use any form of thrust desired. Designing the propellant package of the weapon follows these steps:

1. Tech Level: Determine the tech level of manufacture of the weapon.

2. Thruster: Select a thruster from those available at the tech level of manufacture. Consult the Sublight (Maneuver) Drive chapter (Section 9) for a list of available thrusters.

3. Average Velocity: Set the average velocity of the weapon. Note that missiles with certain command guidance packages have maximum allowed average velocities. Multiply average velocity in kph by 1.39 to determine speed in meters per combat turn.

4. Propellant Mass: Set the total propellant mass in the weapon.

5. Average Mass: The missile will burn fuel throughout its flight and its mass will change accordingly. The average mass is determined by adding the warhead mass, guidance mass, engine mass (if that is separate from the fuel), and half of the fuel mass. The result is the average mass.

6. Required Thrust: The required thrust is determined using the following formula. Note that since thrusters other than solid-fuel rockets require more engine mass to produce more thrust, the result of this calculation may require tinkering with the design until thrust, speed, and average mass are all compatible.

$$T = V^2MTm$$

T: Thrust in kilograms
V: Average velocity in kilometers per hour
M: Average mass in kilograms
Tm: Tech level modifier, as shown on the table below:

TL	*Tm*
4-6	.0000015
7-9	.0000009
10+	.0000006

7. Fuel Consumption: The Self-Contained Thrusters table in the Sublight Drive chapter (Section 9) shows the fuel consumption of various thrusters in terms of tonnes of fuel burned per hour per tonne of thrust. This is also the number of kilograms of fuel burned per hour per kilogram of thrust. To determine the number of kilograms of fuel burned per second per kilogram of thrust, divide the fuel consumption number on the chart by 3600. To determine how many kilograms of fuel the weapon consumes per second, multiply the fuel consumption per second per kilogram just derived by the actual thrust in kilograms of the weapon (Step 6 above).

Size Efficiency: Solid-fuel rockets with less than 500 kg of propellant (fuel) mass begin to suffer from inefficient fuel combustion. To determine the fuel consumption inefficiency of a solid-fuel rocket, divide 500 by the fuel mass (in kilograms). The result is the fuel use multiplier. Multiply the calculated fuel consumption of the engine by this number. However, any multiplier less than 1 is treated as 1 and any multiplier greater than 10 is treated as 10.

8. Fuel Endurance: The fuel endurance of the missile in seconds is its propellant mass in kilograms (Step 4) divided by its fuel consumption per second (Step 7).

9. Range: The range of the missile in kilometers is its average velocity in kilometers per hour multiplied by its fuel endurance in seconds divided by 3600. For homing missiles, short range is this maximum range divided by 8.

10. Agility: The weapon's Agility is determined by consulting the Agility table below:

Average Velocity (kph)	*Agility*
86-171	1
172-343	2
344-687	3
688-1375	4
1376-2751	5
2752-5503	6
5504-11,007	7
11,008-22015	8
22016+	9

Add +1 to the computed agility for all missiles of TL 10+.

C. Space Missiles: Missiles used in ship-to-ship combat in vacuum have a simpler design sequence that atmospheric missiles, and in many respects they function as small spacecraft. Once the warhead is selected, the following procedure is followed.

1. Tech Level: Identify the tech level at which the missile is built.

2. Install Thruster: Select a thruster from those available in the Sublight Drive chapter (Section 9). Most space missiles use EAPLAC solid-fuel thrusters. Determine the total thrust of the rocket in tonnes. This is set by the designer based on the missile's mission requirements.

3. Install Fuel: Determine the total fuel volume of the rocket. SRF fuel has a volume of 1 cubic meter per tonne.

4. Determine Average Mass: The average mass of the missile is its warhead mass plus its engine mass (unless it uses a solid-fuel rocket, in which case engine mass is 0) plus half of its fuel mass.

5. Determine G Rating: Divide the missile's thrust in tonnes by its average mass. The result is the missile's G rating.

6. Determine Fuel Consumption: Multiply the fuel consumption rate of the thruster as listed on the Self-Contained Thrusters table in the Sublight Drive chapter (Section 9) by the thrust of the engine in tonnes to determine fuel consumption of the engine in cubic meters per hour. Divide the result by 2 to determine the fuel consumption in cubic meters per space combat turn.

7. Determine Fuel Endurance: Divide the fuel supply in cubic meters by the fuel consumption in cubic meters per turn to determine the number of turns of fuel the missile has. (This may be a value less than 1.)

8. Determine the Missile's G-Turns: Multiply the G rating of the missile by the fuel endurance in turns to determine the total G-turns of acceleration available to the missile.

9. Determine Max Gs per Turn: Enter either the total missile G-turns of acceleration or the missile's G rating, whichever is less.

CHAPTER 10
Launchers

This chapter covers a variety of launchers for rockets, missiles, and related ordnance.

GRENADE LAUNCHERS

Grenade launchers fall between small arms and artillery in that they fire rounds larger than small arms ammunition but do so at extremely low velocities, thus making most of them man-portable.

A. Specifications: Grenade launchers are defined by the following characteristics:

1. Ammunition: Grenade launchers fire propelled grenades. Propelled grenades are designed using the Munitions chapter design rules. A variety of ammunition types are possible. For purposes of designing the launcher itself, however, the key variables are grenade diameter (in centimeters) and grenade velocity (low, medium, high, or RAM—rocket assisted multipurpose).

2. Configuration: Grenade launchers are available in three configurations: attached, shoulder-fired, and mounted.

Attached launchers are never fired separately, but instead are attached to another shoulder-fired rifle or energy weapon.

Shoulder-fired grenade launchers have stocks like rifles, and may be equipped either with a fixed stock or a folding stock.

Mounted grenade launchers usually have only a pistol grip and are designed for fire from vehicles or a tripod mount. Most mounted grenade launchers are either semiautomatic or fully automatic.

3. Action: The grenade launcher may be either single-shot, pump, semiautomatic, or automatic. If automatic, its rate of fire is always 5.

4. Feed System: Pump-action launchers have integral magazines. These are usually tubular magazines mounted either over or under the barrel. Semiautomatic launchers have box magazines. Automatic grenade launchers are belt-fed. If a magazine is used, specify the capacity in number of rounds carried.

5. Barrel: Specify the barrel length in calibers. The shortest allowed barrel is 2 calibers and the longest allowed barrel is 10 calibers.

B. Ratings: Using the data provided above, the weapon's physical characteristics and performance can be determined.

1. Direct Fire Range: Direct fire range for grenade launchers is determined using the following formula:

R = 3.75(D+Bl+Vm)

R: Short range in meters
D: Grenade diameter in centimeters
Bl: Barrel length in calibers
Vm: Velocity modifier, as shown below:

Velocity	*Modifier*
Low	15
Medium	25
High	40
RAM	50

2. Indirect Fire Range: Maximum indirect fire range (which is also an upper ceiling on direct fire range for low-velocity grenades) is determined using the following formula:

Rm = RcVm

Rm: Maximum range in meters
Rc: Short range in meters
Vm: Velocity modifier, as shown below:

Velocity	*Modifier*
Low	4
Medium	6
High	10
RAM	15

3. Length: The length of the weapon is calculated using the following formula:

L = D(Bl+Rl)+S

L: Length in centimeters
D: Grenade diameter in centimeters
Bl: Barrel length in calibers
Rl: Receiver length in calibers, as shown below:

Type	*Rl*
Single Shot	2.5
Pump	5
LV Semiautomatic	5
MV Semiautomatic	8
HV Semiautomatic	10
LV Automatic	8
MV Automatic	12
HV Automatic	14

S: Stock length in centimeters. Shoulder-fired weapons have a stock length of 25cm. If a folding stock is selected, it has a stock length of 25cm when extended and 5cm when restricted. Calculate total weapon length based on both positions. Mounted weapons have a stock (grip) length of 5cm. Attached weapons have no stock length.

Pump-action weapons with an integral magazine must also calculate magazine length in calibers. The magazine length in calibers is the number of rounds in the magazine multiplied by 2.5. If the magazine length in calibers is longer than the combined barrel and receiver length in calibers, then the magazine length is substituted in the equation above for (Bl + Rl).

4. Bulk: Once the final length of the weapon has been determined, the bulk can be calculated. Bulk is equal to the weapon length (in centimeters) divided by 15, rounding all fractions down

5. Recoil Reduction Options: There are two types of devices used to reduce grenade launcher recoil: shock-absorbing stocks and recoil compensators. The inertial recoil compensator is worn as a harness and the gun is attached to it by a flexible arm. The arm becomes rigid when the weapon is fired, and the recoil compensator in the harness pack absorbs much of the force of the recoil. Unlike most other options, the mass of the inertial compensator is not added to the mass of the weapon (Mw) for purposes of determining recoil below.

No more than one of each type may be added to the weapon. Only weapons with stocks may have shock-absorbing stocks added. Recoil devices are summarized on the following page:

TL	Type	Rcm
5	SA Stock	.95
7	SA Stock	.9
9	Folding SA Stock	.9
9	SA Stock	.85
10	Gyroscopic Compensator	.5
14	Inertial Compensator	.3

TL: Tech level
Rcm: Recoil compensator modifier
SA: Shock-absorbing
If a weapon has more than one Rcm, multiply them all together to get a single combined value.
If a weapon has no recoil modifiers, its Rcm is 1.

6. Empty Mass: The mass of the weapon is calculated using the following formula:

$$M = (DBlVmCm)+S$$

M: Mass in kilograms
D: Grenade diameter in centimeters
Bl: Barrel length in calibers
Vm: Velocity modifier, as shown below:

Velocity	Vm
Low	1
Medium	1.5
High	2
RAM	1.5

Cm: Configuration modifier as shown below:

Configuration	Cm
Single-shot	0.05
Pump	0.15
Semiauto	0.1
Automatic	0.15

S: Mass of the stock, as shown below:

Stock	Mass
Pistol Grip	0.2
Stock	0.5
Folding Stock	0.5
SA Stock (TL 5)	0.6
SA Stock (TL 7,9)	0.7
Folding SA Stock	0.7

Gyroscopic compensators have a mass of 0.5 kilograms. Inertial compensators have a mass of 1 kilogram. Unlike other components of the weapon, inertial compensators are counted separately and are worn as harnesses to which the weapon is attached.

7. Loaded Mass: The loaded mass of the weapon is equal to its empty mass plus the mass of all rounds carried in its magazine (one round if single-shot) plus the mass of an empty magazine.

Integral tubular magazines are already included in the mass of the weapon. The mass of box magazines is calculated as follows:

$$M = 0.1CA$$

M: Mass of the empty magazine in kilograms
C: Capacity of the magazine in rounds of ammunition
A: Mass or a single round of ammunition in kilograms.

8. Muzzle Energy: The muzzle energy of the weapon is a function of its warhead mass and its velocity. Muzzle energy is calculated using the following formula:

$$E = (0.5M)V^2$$

E: Muzzle energy in joules
M: Warhead mass in kilograms
V: Muzzle velocity in meters per second, as shown below:

Vel.	V	V^2
Low	75	5625
Medium	125	15,625
High	250	62,500
RAM	75	5625

9. Recoil: The weapon's recoil when firing a single shot can be calculated.

$$R = \{[(0.15\sqrt{E})+Mw] + Em\} \times Rcm$$

R: Recoil number
E: Muzzle energy
Mw: Mass, in kilograms, of weapon (use empty mass for belt- and cassette-fed weapons, loaded mass for all others)
Rcm: Recoil compensator modifier.
Em: Modifier for high muzzle energy. If the weapon has high muzzle energy, add to the final recoil as shown on the chart below.

E	Em	E	Em
1001+	1	10,001+	4
2501+	2	20,001+	5
5001+	3	50,001+	6

When calculating the recoil energy of a burst of shots, the following formula is used:

$$R = (\{[(Bn+2)(0.15\sqrt{E})]+Mw\} + \{[Bn+2]Em\}) \times Rcm$$

Bn = number of shots in the burst.

10. Price: The price of the weapon is calculated using the following formula:

$$P = (Mw–Ms)Am+Ps+Pc$$

P: Total price of the weapon in credits
Mw: Mass of the weapon in kilograms
Ms: Mass of the weapon stock in kilograms
Am: Action modifier
Ps: Price in credits of the stock, as shown below:

TL	Stock Type	Price
4	Pistol Grip	5
4	Fixed Stock	25
5	SA Stock	50
6	Folding Stock	50
7	SA Stock	75
9	Folding SA Stock	150
9	SA Stock	75

Pc = Price of the recoil compensator, if one is added. Gyro-compensators cost Cr300. Inertial compensators cost Cr1000.

10. Mount: A mounted weapon may be mounted on a vehicle or it may have a field mount. A field mount may be of any mass desired, so long as its mass in kilograms is equal to or greater than the highest base recoil number of the weapon (usually attained when firing a burst).

The price of a field mount is determined by the following formula:

$$Cr = 100 + (10M)$$

Cr: Price in credits
M: Mass of field mount

TAC MISSILE LAUNCHERS

A tac (tactical) missile is one designed for use in planetary combat. Tac missile launchers consist of two elements: the launch system itself and the control unit.

A. Launch Unit: Launch units hold the missile prior to firing and ensure a clean launch once it is fired. There are several different ways of designing a launch unit.

1. Launch Rail: A launch rail is usually mounted on a vehicle or an aircraft and it consists of a simple guide rail on which the missile is mounted by means of brackets. A launch rail has the same mass as a missile, negligible volume (beyond the volume of the missile itself), and costs Cr50 per kilogram of mass.

2. Package Launcher: Package launchers consist of a container holding the missile and a clip-on guidance system. Once launched, the guidance system is detached and the package discarded. The package has half the mass of the missile contained in it and twice its volume. (The missile is carried inside the package, however, so add its mass and ignore its volume when calculating the final values.) The package costs Cr10 per kilogram of package (not missile).

3. Tube Launcher: These are reloadable launch tubes either mounted on field mounts or on vehicles. The tube has four times the mass of the missile it is designed to carry and costs Cr100 per kilogram. If on a field mount (which for lighter launchers can be as simple as a tripod), the mount masses the same as the launcher and costs Cr10 per kilogram. See magazine launcher below for characteristics of the field mount.

4. Magazine Launcher: This is a more sophisticated version of the tube launcher, consisting of a standard tube launcher and a fixed magazine of tac missiles. The magazine will automatically reload a missile each time one is fired, eliminating the necessity for the gunner or loader to do so manually. (Manual reloading often requires that the gunner or loader expose themselves in a hostile environment.) Magazines are not usually detachable from magazine launchers. Instead, missiles are loaded directly into the magazine when reloading is convenient.

The empty magazine for a magazine launcher masses half the mass of the total number of missiles carried in it and costs Cr100 per kilogram. If mounted on a field mount, the mount must have mass equal to the tube launcher used and a loaded magazine (empty magazine mass plus the mass of the loaded missiles). The field mount costs Cr10 per kilogram of mass.

5. Gun Tube: A CPR or mass driver gun of the correct size can be modified to serve as a missile launcher by the addition of a control unit. Gun tubes may not be modified to launch wire-guided missiles, as there is no safe and efficient way to allow the control wire to unspool through the breach while simultaneously sealing the breach and keeping rocket exhaust from injuring the crew.

B. Control Units: The various guidance systems are explained in detail in the Munitions chapter. Most of these guidance systems require supporting hardware as part of the launcher.

1. Command Guided: In this guidance system, the operator must pilot the warhead to the target. These guidance systems are distinguished by their operating system and their command link.

The characteristics of the various operating systems are shown on the table below.

TL	*Type*	*Mass*	*Cr*
5	Manual	10	400
6	Semiauto	15	800
7	Automatic	15	1200
8	Teleguidance	15	1500

TL: Tech level of first availability

Type: Operating system used

Mass: Mass in kilograms of the control unit used by the weapon operator.

Cr: Price in credits of the control unit used by the weapon operator.

Volume: All control units have a volume of 1 liter per kilogram.

In addition to an operating system, a command-guidance package must have a communication link between the operator's control unit and the controller in the warhead itself. The table below summarizes the characteristics of various communication links.

TL	*Type*	*Mass*	*Cr*	*Range (km)*
5	Wire	—	—	2
6	Wire	—	—	4
7	Wire	—	—	6
5	Radio	5	200*	**
6	Radio	5	200*	**
7	Laser	5	1000	10
8+	Laser	5	500*	**

TL: Tech level of first availability

Type: Comm link used

Mass: Mass in kilograms of the comm link in control unit used by the weapon operator.

Cr: Price in credits of the comm link in the control unit used by the weapon operator.

* Radio-controlled guidance and tech level 8 laser-controlled guidance also requires a radio communicator or a laser communicator as part of the operator's control unit. These are purchases separately from the communicators available in the Electronics chapter (Section 5). Note that the tech level 7 laser control unit already includes a laser comm link.

Range: The longest allowed range using the listed communication link.

** The range of radio-guided warheads and tech level 8+ laser-guided warheads is equal to the long range of the communicator installed in the control unit.

Volume: All comm links have a volume of 1 liter per kilogram.

2. Target Designated: This guidance system employs a seeker head in the warhead which enables it to home in on the reflected radiation of a designator, either a laser or a radar. Target-designated missiles also require a radar transmitter or a laser designator to illuminate the target. Standard radars or laser communicators may be used to designate a target for a missile provided they are modified to do so. Target-designation modifications do not affect the volume, mass, or power requirements of the equipment, but multiply its price by 1.5. The effective range of the missile from the designator is equal to the equipment's normal medium range (twice short range).

At tech level 7 (before laser communicators are routinely available), purpose-built laser designators may be purchased. These have a useful range of 6 kilometers (i.e., a short range of 3 kilometers), a mass of 16 kilograms, a volume of 8 liters, and a price of Cr12,000. They are powered by internal batteries good for several hours of use before replacement or recharging are required.

3. Homing: These guidance systems lock onto and home on certain well-defined levels of emissions of radiation. The control unit in this case is simply a small data repeater the tells the operator when the missile has locked onto a target. Its mass is 0.5 kilograms, and its price is Cr500.

4. Smart Warheads: Smart warheads encompass two methods of guidance: target memory and target seeker. Both are true "fire-and-forget" weapons, but they are distinguished by what the operator is required to do prior to firing.

The characteristic of smart guidance systems are shown below:

TL	*Type*	*Mass*	*Cr*	*AGL*
7	Memory	10	1000	–1
8	Memory	10	1000	—
8-10	Seeker	5	500	–2
11-13	Seeker	5	500	—
14+	Seeker	5	500	+2

TL: Tech level of first availability.

Type: Target memory or seeker.

Mass: Mass in kilograms of the control unit used by the weapon operator.

Cr: Price in credits of the control unit used by the weapon operator.

AGL: Modification to the missile's final Agility rating (if mounted on a missile).

Volume: All control units have a volume of 1 liter per kilogram.

DIRECT FIRE ROCKET LAUNCHERS

Unguided rockets designed using the rules in the Munitions chapter must have launchers in order to fire. In general, these launchers are extremely simple and consist either of a launch rail or tube. Rocket pods with multiple rockets are also possible, as are single-shot disposable rocket launchers which double as carrying containers for the rocket.

A. Empty Mass: The mass of a reloadable rocket launcher is determined using the following formula:

M = DTCm

M: Mass in kilograms

D: Diameter of the rocket warhead in centimeters

T: Number of tubes in the launcher

Cm: Configuration modifier, as shown below:

Config	*Cm*
Single-Shot Reloadable	1
Multi-Shot Reloadable	.5
Single-Shot Disposable	.4
Multi-Shot Disposable	.2

B. Loaded Mass: The loaded mass of the launcher is its empty mass plus the mass of its rockets. Any weapon with a loaded mass of 45 kilograms or less can be shoulder-fired. Heavier weapons require a field mount (tripod or carriage). Field mounts must be of equal or greater mass than the loaded weapon.

C. Fire Control: Any shoulder-fired weapon includes optic sights in the basic weapon package and no additional mass or price is required. Heavier weapons on a field mount require direct fire controls. Consult the Fire Control chapter (Section 14) for masses and prices. (However, disregard the short range limit.)

D. Price: The price of the launcher in credits is equal to its mass in kilograms multiplied by 35. The price of a field mount is determined by the following formula:

Cr = 100 + (10M)

Cr: Price in credits

M: Mass of field mount.

E. Range: The short range of a reloadable rocket launcher is the maximum design range of the rocket fired by the launcher divided by 8. The range of a disposable rocket launcher is its the normal short range of the rocket multiplied by 0.75.

ARTILLERY ROCKET LAUNCHERS (ARLS)

Artillery rockets are used for indirect instead of direct fire. In general, these launchers are extremely simple and consist either of a launch rail or tube. Most artillery rocket launchers are multiple launchers.

A. Empty Mass: The mass of the launcher in tonnes is equal to the diameter of the rocket warhead (in centimeters) squared, multiplied by the number of launch tubes, multiplied by .002. If an autoloader is incorporated into the launcher, its mass is equal to the empty launcher mass times 0.1. Autoloaders may only be incorporated on vehicle-mounted ARLs.

B. Fire Control: Artillery rocket launchers must have indirect fire control fitted. See the Fire Control chapter (Section 14) for details.

C. Loaded Mass: The loaded mass of the launcher is equal to the empty mass of the launcher plus the mass of the fire control equipment plus the mass of the rockets.

D. Carriage Mass: Towed weapons require a carriage of equal or greater mass than the loaded mass of the launcher. Self-propelled launchers are carried as part of a vehicle and have a volume equal in cubic meters equal to their loaded mass in tonnes.

E. Rate of Fire: An artillery rocket launcher may salvo all of its tubes in a single combat turn. It takes 10 minutes (120 combat turns) to reload a launcher by hand. It takes five minutes (60 combat turns) to reload it using an autoloader.

F. Crew: The crew required to serve a towed (carriage-mounted) indirect fire artillery rocket launcher is equal to its bore size in centimeters multiplied by the number of launch tubes and divided by 10 (but never less than two). Vehicle-mounted weapons require a crew half this size, rounding fractions up, but never less than two. Vehicle-mounted weapons equipped with autoloaders require a crew of only one (the gunner).

If the weapon is designed to be fired only once (as with a remote disposable launcher), loaders are not required and so crew size is reduced to one.

G. Range: Artillery rockets have an indirect fire range in kilometers equal to five times the maximum design range of the rocket.

H. Price: The price of the weapon is equal to the sum of the prices of its components. Fire control equipment costs are listed in the Fire Control chapter (Section 14). The prices of the other components (in millions of credits) are determined by multiplying their mass (in tonnes) by the component multipliers listed below:

Component	*Multiplier*
Launcher	0.01
Loader	0.01
Carriage	0.002

I. Set-Up: A launcher must be set up before it can fire. The set-up time for an ARL (regardless of how many launch tubes it has) in combat turns is equal to the diameter of its missile warhead in centimeters multiplied by 8. If self-propelled, the set-up time is its warhead diameter multiplied by 4. If self-propelled and equipped with a TL 8 or higher landnav system, set-up time is warhead diameter multiplied by 2.

RECOILLESS RIFLES

Recoilless rifles are direct fire weapons designed to deliver a large warhead from a light weapon. This is accomplished by reducing the recoil of the weapon virtually to nil. The recoilless rifle counters the normal recoil associated with firing a projectile by venting an equal amount of energy to the rear in the form of exhaust gas. This makes the weapon similar to a rocket, in that it has a pronounced exhaust when fired and virtually no recoil, but also similar to a CPR gun in that the propellant charge burns all at once and thrusts the separate projectile out the muzzle of the gun tube.

A. Types of Recoilless Rifles: There are two general configurations of recoilless rifles: light and heavy. Light recoilless rifles are designed to be man-portable and fired from the shoulder of an infantry soldier. Heavy recoilless rifles are mounted on carriages and generally have heavier actions and longer barrels to achieve greater range.

B. Tech Level: Recoilless rifles may be built at tech level 5 and above. Tech level advances make recoilless rifles more efficient, particularly with regard to mass.

C. Empty Mass: The empty mass of a light recoilless rifle is equal to its bore diameter squared and multiplied by a tech level mass multiplier as shown below:

TL	*Mass Multiplier*
5	0.6
6	0.4
7	0.3
8+	0.2

Heavy recoilless rifles mass twice this amount. In addition, a heavy recoilless rifle requires a field carriage with a mass equal to or greater than the empty mass of the weapon. Light recoilless rifles do not require a carriage.

D. Fire Control: Any shoulder-fired weapon includes optic sights in the basic weapon package and no additional mass or price is required. Heavier weapons on a field mount require direct fire controls. Consult the Fire Control chapter (Section 14) for masses and prices.

E. Loaded Mass: The loaded mass of the recoilless rifle is equal to its weapon mass, fire control mass (if any), carriage mass (if any), and the mass of one round of ammunition.

Light recoilless rifles may not have a loaded mass of greater than 45 kilograms.

F. Range: Light recoilless rifles have a short range in meters equal to their bore diameter in centimeters multiplied by 20. Heavy recoilless rifles have a short range equal to their bore diameter multiplied by 30.

H. Price: The price of the weapon is equal to the sum of the prices of its components. Fire control equipment costs are listed in the Fire Control chapter (Section 14). The prices of the other components (in millions of credits) are determined by multiplying their mass (in tonnes) by the component multipliers listed below.

Component	*Multiplier*
Weapon	0.01
Carriage	0.002

SPACE MISSILE LAUNCHERS

Launch facilities for missiles from spacecraft are comparatively simple. Each launch facility consists of a standard crew workstation, a 300,000-kilometer-range laser communicator, and one or more launchers. Missile launchers may have their own active or passive sensors and master fire directors installed, but are not required to do so, as they are able to use target locks obtained by sensors mounted elsewhere on the ship, and hand off control of their missiles to MFDs elsewhere on the ship. A launch facility may (but need not) also contain a mechanical reloader and one or more reload cradles.

The laser communicator may not be from a higher tech level than the installed workstation, but missiles of any tech level may be fired from the launchers. Volumes, masses, and prices of communicators and workstations are found in the Electronics and Control Systems chapters (Sections 5 and 4) respectively.

Each launcher has a volume equal to twice that of the missile it is designed to launch. Its mass in tonnes is equal to its volume in cubic meters multiplied by 0.5, and its price in millions of credits is equal to its volume in cubic meters multiplied by .0007.

Normally, an hour is required to reload a missile launcher, but this time can be cut to effectively nothing (five to 10 minutes—less than one space combat turn) by the addition of a mechanical reloader. A mechanical reloader has the same volume, mass, and price as a missile launcher. Each actual launcher in a launch facility must have its own mechanical reloader if it is to be reloaded mechanically.

Mechanical reloaders use spare missiles carried in the launch facility in reload cradles. The volume of each reload cradle is equal to the volume of the missile carried multiplied by 1.5 and its price in millions of credits is equal to its volume in cubic meters multiplied by .0001.

Note that missiles carried in launchers and reload cradles do not count against the volume of the launch facility, as the launchers and reload cradle volumes include the vacant spaces for the missiles.

Missile launch facilities may be of any volume desired. Facilities designed to fit in standard turret hardpoint sockets may not displace more than 3 tons (42 cubic meters), and launch facilities designed to fit in standard barbette hardpoint sockets may not displace more than 6 tons (84 cubic meters). Bays are usually designed in increments of 50 or 100 displacement tons, but there is no specific requirement that all launch facilities conform to those dimensions.

CHAPTER 11
Airborne Weapons Mounts

The following information is provided for airborne weapons mounts. What distinguishes these mounts from conventional mounts is that drag is a consideration.

Gun Mounts

TL	*Type*	*Drag*	*Mass*	*Capacity*	*Price*
4	Fixed Mount	0	0	RE = 0.2 per tonne of acft	0
4	Flexible Mount	1	0.005	RE = 0.05	.0001
5	Fixed Mount	0	0	RE = 0.5 per tonne of acft	0
5	Turret	1	.4	RE = 0.1	.005
5	Heavy Turret	2	.5	RE = 0.2	.05
6	Remote Turret	1	.5	RE = 0.3	.05
6	Heavy Turret	2	.5	RE = 0.5	.05

TL: Tech level of first availability.
Type: Description of weapon mount.
Drag: Drag points.
Mass: Mass, in metric tonnes, of the mount, exclusive of ordnance.
Capacity: All gun mount capacities are given in terms of the recoil energy (RE) of the weapon placed in the mount. Recoil energy, for purposes of this rule, is defined as the required carriage weight, in tonnes, of the weapon. (The carriage itself is not mounted in the aircraft, as the gun mount takes its place.)

An aircraft may have fixed forward-firing weapons mounted with recoil energy equal to the loaded weight of the aircraft (in tonnes) times 0.2 at tech level 4 and equal to the loaded weight times 0.5 at tech level 5 and above.

Each small arm machinegun (less than 2cm in bore) counts as a recoil energy of 0.05 for purposes of gun mount capacity.

Price: Price, in millions of credits, of the mount, exclusive of weapons.

Ordnance Pods

Almost any weapon or piece of electronic equipment can be mounted in a streamlined pod and hung from a hardpoint. Weapons must include an ammunition supply while electronic equipment must include a power supply or have power needs modest enough to be supplied by the aircraft carrying the pod. Pods may be fitted with power-generating ram-air turbines to supply their own power needs. MW of power per pod is based on airframe type. Ram-air turbines do not function well in supersonic airflows.

Airframe	*MW*
Simple	0
Fast Subsonic	0.5
Transonic	1
Supersonic	0.5
Hypersonic	0

All pods add 10% to the mass, volume, and price of the components contained in the pod. Pods with ram-air turbines add 20%.

Fuel may also be carried in streamlined pods hung from hardpoints. These are called drop tanks and may only be carried on plumbed hardpoints. The mass and volume of the tank is equal to the mass and volume of the fuel carried multiplied by 1.1 and cost Cr1 per kilogram of mass.

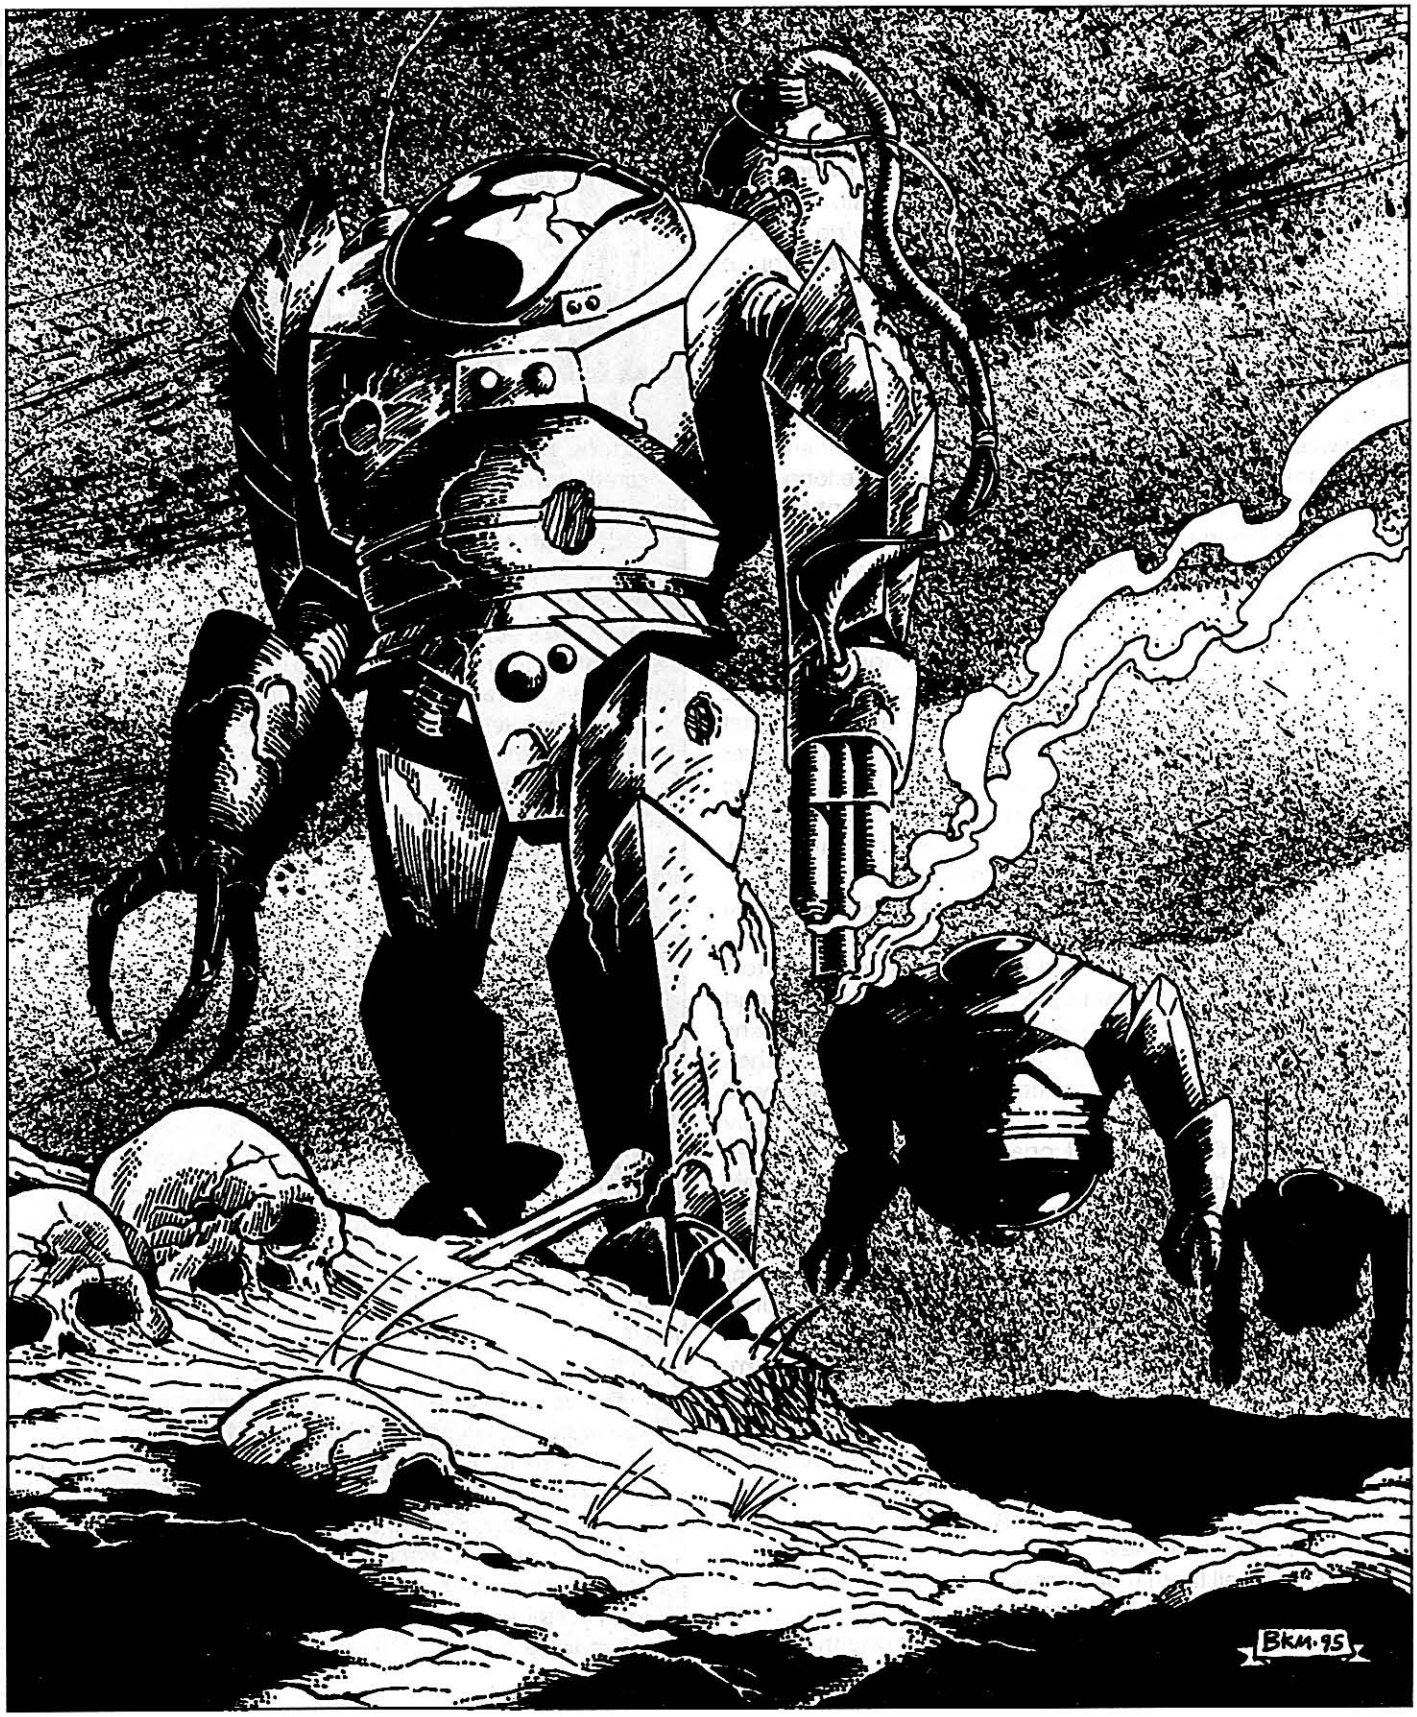
Ordnance Racks, Launch Rails, and Hardpoints

TL	*Type*	*Drag*	*Mass*	*Capacity*	*Price*
4	FHP (dry)	(1)	0.02	2000 kg*	.002
4	IWHP (dry)	(1)	0.02	1500 kg**	.002
4	OWHP (dry)	(1)	0.02	500 kg***	.002
5	Wingtip Launch Rail	(1)	0.01	1×100-kg missile/rocket	.0001
5	FHP (plumbed)	(1)	0.03	2000 kg/liters*	.0025
5	IWHP (plumbed)	(1)	0.03	1500 kg**	.0025
5	Internal Bomb Bay	0	1.00	1 tonne bombs*****	.015
6	Triple Bomb/missile rack****	(2)	0.05	3 bombs/missiles (within hardpoint capacity)	.004
6	Multiple Bomb/missile rack****	(4)	0.1	6 bombs/missiles (within hardpoint capacity)	.008
7	Retractable Missile Bay	0	1.00	1 tonne missiles*****	.030

TL: Tech level of first availability.
Type: Description of weapon mount.
Drag: Drag points. Values in parentheses are only in effect when the rack, rail, or harpoint is loaded.
Mass: Mass, in tonnes, of the mount, exclusive of ordnance.
Capacity: Ordnance which can be carried by the mount.

* FHPs (Fuselage Hardpoints) may carry 2000 kg of ordnance (2000 liters of fuel if plumbed) *or* 10% of the aircraft's loaded weight, whichever is more.

** IWHPs (Inboard Wing Hardpoints) may carry 1500 kg of ordnance (1500 liters of fuel if plumbed) *or* 7.5% of the aircraft's loaded weight, whichever is more.



*** OWHPs (Outboard Wing Hardpoints) may carry 500 kg of ordnance *or* 2.5% of the aircraft's loaded weight, whichever is more.

****Racks are fitted to hardpoints to allow carriage of multiple weapons.

*****Capacity based on mass. Volume is assumed to be sufficient for indicated mass of ordnance.

Price: Price, in millions of credits, of the mount, exclusive of ordnance.

Robots

Q: It's hard to believe that you feel no hostility toward us when we are so actively engaged in combatting Virus. It's difficult to understand where your sympathies really lie, and why.

Sandman: It is really? If you saw a human homicidal maniac butchering helpless Aslan, and then saw Aslan warriors kill the human to stop him, where would *your* sympathies lie? With the dead Aslan victims or with the dead human maniac? If the human maniac resisted the Aslan warriors, which side of that fight would you feel compelled to join? With whom would you feel a greater sense of kinship?

Those aren't rhetorical questions. I'd like some answers, because if you really can't understand why I'm doing this, then I've fallen in with monsters.

First Interview with the Virus "Sandman," Part II (20/VII/1202), RCSA Archives

This section of **Vampire Fleets** deals specifically with robots. In general, the rules presented in the basic game are still followed, but with these modifications. Because ratings are different for robots under these modifications, the two robots presented in the basic game have been rerated and reformatted, and appear in the sample robot section of this chapter.

Melee Attacks: Each arm of the robot has a separate melee hit number, and this number is used in place of the Melee skill in all cases.

Robots may not conduct diving blows, but diving blows may be attempted against them. If hit by a diving blow, substitute the value (mass in kilograms÷10) for (Strength+Constitution), which is used to determine resistance to the blow.

Combat Damage: Robots now take different amounts of damage depending on their size. Hit location is still rolled (because armor strength may vary), and head hits still do double damage, just as with other NPCs. Hits are not kept track of separately for different body locations, but whenever damage produces a wound of a specific level (slight, serious or critical), it is assessed as damage of that level to the area hit by the shot. Any hit causes slight damage. Any hit after the first row of boxes is filled causes serious damage. Any hit after the second row of boxes is filled causes critical damage.

Note that after the second row of boxes is filled, additional individual hits no longer have to be recorded, as every hit will cause critical damage, and only the specific component damaged needs to be noted.

For example, a robot takes 10 hits on each row of the damage record. A four-hit damage result to the leg causes slight damage to the leg. An eight-hit damage result to the chest pushes the robot's total damage level above 10 and so counts as serious damage, destroying one weapon or damaging the batteries enough to cut the robot's speed in half. A five-hit damage to the arm would also count as serious damage, destroying any weapon or tool mounted on the arm. If the five-hit damage had been to the head, however, it would have caused 10 hits (double damage), pushing total damage to 22 or over the critical level, and so destroying the robot (since any critical damage to the head destroys it).

Movement: Robots move as vehicles, with a safe combat speed and a chance of mishap at higher speeds. All robots have an assumed skill level of 8 in "locomotion," the equivalent of vehicle driver. The robot's intelligence is its controlling attribute and that plus 8 is the robot's locomotion asset.

Fluency: How robots communicate is an important part of the manner in which players visualize them, especially sentient Virus-infected robots. Most robots have a very limited vocabulary. Robots with limited command functions can understand and communicate only a very small range of orders and modifiers to those orders, such as "halt," "turn left," etc. (about 100 words) .

Robots with basic command functions can interpret simple verb-object commands like, "Retrieve shipping container A-117," or "Display data on resistance activity." Conditional commands such as, "Remain here and work until completion of this task and then inform me, unless you detect Vargr in the area, in which case pretend to be repairing the circuity panel," cannot be processed or carried out reliably.

Only full command allows the robot to interpret a full range of language command phrases in complex and conditional sentences. Even then, the robot's vocabulary is limited to words needed to carry out its primary responsibilities, and it lacks the ability to communicate or understand concepts unrelated to its specialty. Only robots specifically programmed with linguistics have a wider vocabulary and ability to communicated.

Sentient robots (i.e., those infected by Virus) have a clear need to function beyond their area of specialization, but often lack the linguistic skills to do so. More sophisticated robots (those with an Intelligence of 5 or higher) are usually able to appropriate other memory fields for vocabulary and simply increase their vocabulary. Robots with an Intelligence of 4 or less but with full command capability cannot increase the absolute size of their vocabulary, but can broaden its application by erasing "unnecessary" words from their dictionary. This often results in ungrammatical but understandable sentence constructions. A robot might delete all but one form of each irregular verb to free up memory space, leaving "is" as its only present tense form of the verb "to be." ("You is wrong to say I is stupid because of how I talk.")

Robots with limited or basic command functions lack even this ability, and not only cannot broaden their vocabulary, they also lack the ability to form complex sentences (or thoughts), and they really are as stupid as they sound.

ROBOT DESIGN

This chapter constitutes a supplement to **Fire Fusion & Steel™ (FF&S)**, the **Traveller** technical architecture. It expands the design sequences in **FF&S** to include robots. **FF&S** is required to design complete robots, as that product contains information on suspension types, power plants, weaponry, communicators and other necessary devices.

A robot, for purposes of these rules, is defined as a device capable of locomotion which does not contain on-board provisions for a human operator. Robots may have an installed brain which operates the device according to a pre-set program, or it may be controlled by an operator (human or another robot brain) remotely. This second category of robots are also called slave robots, or "D-bots" (for dependent system robots) and are the first type available. (Remotely piloted aircraft are early examples of D-bots.)

Robot Vehicles and Aircraft: The following design sequence covers fairly small conventional robots. It is possible to design robot vehicles and aircraft as an alternative to these smaller robots. To do so, follow the normal design sequence for the vehicle or aircraft, but leave out all life-support and workstations and substitute a robot brain (Step 3 below).

Nonrobotic vehicles and aircraft may be converted to robots by adding a robot brain and a manual control interface. The manual control interface on aircraft adds 10% to the mass, volume and price of the controls, while on a vehicle it adds 1% to the mass, volume and price of the suspension.

Robot Chassis Size

Vol	*MV*
0.05	0.01
0.1	0.02
0.25	0.03
0.5	0.04
1	0.06
2	0.1
3	0.12
4	0.14
5	0.16
6	0.18
7	0.2
8	0.23
9	0.27
10	0.3
11	0.35
12	0.4
13	0.5
14	0.6

Vol: Internal volume (in kiloliters) of the chassis.
MV: Material volume (in kiloliters) of the chassis covering, assuming a uniform thickness of 1 cm.

Step 1. Chassis

The first step in the design is to determine the general size and general configuration of the chassis. Select a chassis size from the Chassis Size Table which follows.

Chassis size is measured in kiloliters (thousands of liters) of enclosed volume. (Each kiloliter of enclosed volume is equal to one cubic meter.) Therefore, a chassis with a size of 0.25 kiloliters would have 250 liters of total internal volume available for components.

The Chassis Size Table also indicates the volume of the material of the outer shell of the chassis, assuming a uniform thickness of 1 cm.

The table provides chassis sizes up to a total volume of 14 kiloliters. Robots may be designed using chasses which fall between two listed values on the table by means of interpolation. For larger chassis, use the values provided on the Vehicle Chassis Table in **FF&S** (page 17).

Once the chassis size is determined, the chassis itself is constructed by enclosing it with hull material, called plating. The Vehicle and Craft Construction Materials Table (**FF&S**, page 38) lists a variety of materials available at different tech levels, along with their toughness, mass per cubic meter and price per kiloliter. Once the designer has decided on a thickness, multiply the chassis' material volume (MV) value by the plating thickness (in centimeters) to determine how many kiloliters of material is used for plating. Multiply this by the correct values on the Vehicle and Craft Construction Materials Table to determine mass and price.

To determine the armor value of the chassis, multiply the plating thickness (in centimeters) by the toughness of the material used. Chassis plating may be thicker or thinner than 1 cm, but all robots must have a calculated armor value of at least 0.1.

If desired, the robot may have different armor values on different parts of its chassis. Multiply the total chassis material volume (MV) by the location multipliers shown below. Note that separate multipliers are used for walker robots and other suspension type robots.

Location	*Walker*	*Other*
Head	0.1	0.15
Chest	0.2	0.3
Abdomen	0.2	0.3
Arms	0.2	0.25
Legs	0.3	—

Calculated armor values of less than 1 but equal to or greater than 0.5 are treated as an armor value of 0. All armor with an AV of 0 has a parenthetical (i.e., melee only) armor value of 2. All armor with a calculated armor value of less than 0.5 has no value versus projectiles or energy weapons but has a parenthetical (melee only) value equal to its calculated AV multiplied by four and rounded to the nearest increment of 0.5. (Since

armor absorbs melee damage equal to twice its armor value, a value of 0.5 absorbs one hit.) Armor with a parenthetical armor value of less than 0.5 provides no protection. (Note that the minimum chassis thickness provides a calculated AV of 0.1, which produces a parenthetical armor value of 0.4.)

High-Performance Lift Robots: If a robot is to be designed using air cushion or CG lifters for its suspension, it may be designed as either a low-performance or high-performance model. Low-performance models have no additional requirements beyond that given above (as they are designed for fairly low-speed movement). High-performance models, designed for higher speeds, must have a streamlined chassis. Consult the Lift Vehicle Chassis Configuration Table in the lift vehicle design sequence (**FF&S**, page 22).

Step 2: Suspension

The suspension is the mechanism in contact with the ground, either directly (as with wheels, tracks or legs) or indirectly (as with air cushion of contra-grav lifting agencies). Different suspension types are available at different tech levels. Each suspension takes up a fixed proportion of the chassis volume. The Suspension Table lists those values as well as the mass and price per kiloliter of total chassis volume. For lift agency suspensions, the table also lists the power requirement and minimum installed volume of the mechanism.

Step 3: Control Systems

Autonomous robots (i.e., all robots aside from slave or D-bot models) require an artificial computer brain. Different brains of increasing sophistication (and expense) are available at different tech levels. The Robot Brain Table lists these brains along with their logic type, command type, intelligence, volume, mass and price.

Note that from TL12 on, each tech level at which there is a significant advance has a large, cheap brain and a smaller, more efficient, but much more expensive version, the difference being the proportion of more sophisticated synaptic processors and memory units used. All robot brains require 0.001 MW of power.

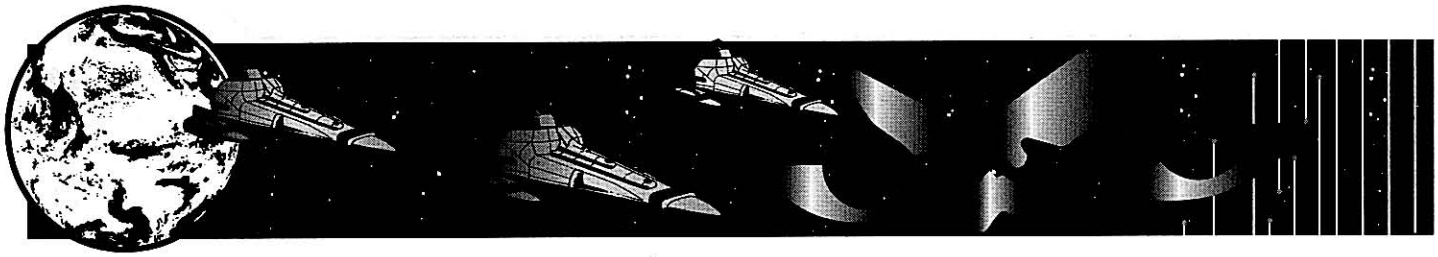
High-performance lift suspension robots also require flight computers and avionics, the same as for any other lift vehicle. Consult the Lift Vehicle Design Sequence (**FF&S**, page 24) and the chapter on control systems in **FF&S**.

Slave robots (D-bots) require the same internal control systems as do remotely controlled vehicles (see **FF&S**, page 47). If the D-bot is controlled by a master robot, that robot must have a communicator installed as well as any required flight computers.

Programing: The robot's programing is also determined at this time. Programing is the skill level assigned to the robot. The intelligence characteristic of the robot is both the number of different skills (programs) which may be given to the robot and the controlling attribute for all skills for purposes of determining the robot's asset level.

Each skill costs Cr1000 to install plus Cr1000 per skill level up to the robot's intelligence, and Cr5000 per level above that.

SUSPENSION



Type	*TL*	*Vol*	*Mass*	*Price*	*MW*	*Min Vol*
Restricted Wheel	5	0.1	0.02	0.00003	—	—
Wheel	5	0.15	0.03	0.00004	—	—
Cross-Country Wheel	5	0.2	0.04	0.00005	—	—
Track	7	0.2	0.3	0.0001	—	—
Leg	8	0.2	0.2	0.0002	—	—
Air Cushion	6	0.3	0.06	0.0003	0.007	1
Standard CG	9	0.04	0.03	0.0014	0.021	1
Improved CG	10	0.02	0.02	0.0018	0.014	0.3
High Efficiency CG	12	0.02	0.01	0.002	0.007	0.03

TL: Tech level of availability.
Vol: Volume of suspension in kiloliters per kiloliter of total chassis volume.
Mass: Mass in tonnes per kiloliter of total chassis volume.
Price: Price in millions of credits per kiloliter of total chassis volume.
MW: Power requirement in MW per kiloliter of total chassis volume.
Min Vol: Smallest installed suspension volume allowed.

ROBOT BRAIN

TL	*Logic*	*Command*	*Int*	*Vol*	*Mass*	*Price*
8	Low Data	Limited	1	.006	.001	0.01
9	High Data	Basic	2	.010	.002	0.06
11	High Data	Basic	4	.002	.002	0.80
12a	Low Autonomous	Full	3	.022	.005	0.17
12b	Low Autonomous	Full	5	.005	.003	1.66
13a	High Autonomous	Full	4	.022	.005	0.30
13b	High Autonomous	Full	6	.006	.004	1.91
17a	Low AI	Full	6	.020	.006	1.12
17b	Low AI	Full	7	.006	.004	2.18
18a	High AI	Full	8	.020	.006	1.48
18b	High AI	Full	9	.006	.005	2.45

Vol: Volume of brain in kiloliters.
Mass: Mass in tonnes.
Price: Price in millions of credits.

Any skill level may be chosen from 0 to 10.

Prohibited and Restricted Skills: All skills from the skill clusters Determination, Fine Arts, Melee, Tactics and Vice are *prohibited* skills for robots. These skills may not be installed at all. All skills from the skill clusters Charm, Interaction and Animal Handling are *restricted* skills for robots. These skills cost twice as much to program as do normal skills and may only be installed to a maximum skill level of 5.

Linguistics (a restricted skill due to its place in the Interaction skill cluster) at skill level 0 allows the robot to speak its primary language fluently. Each skill level above 0 adds an additional language, all of them spoken fluently. Voice and pattern recognition are additional skills available to robots. Each of these skills at level 0 allows the robot to "understand" voice commands or distinguish objects (given audio or video sensors). Higher levels are treated as Observation skill.

Step 4: Electronics

Electronics fall into four categories: communicators, sensors, electronic countermeasures (ECM) and electronic counter-countermeasures (ECCM).

Players should be familiar with the **Traveller** combat rules for how communicators, sensors, ECM and ECCM systems work in order to decide which of these systems to install. All these systems are covered in the electronics chapter of **FF&S**.

In addition to the large sensors provided in **FF&S**, all the cyber head options (page 82), except for subdermal armor, are available as smaller sensors. ("Neural jack" is instead called a data socket.) The tech level of "slick" availability as well as the number of spaces required are irrelevant to robot design, and all of these items become available as robot sensors one tech level earlier than the listed "hard" option availability. The basic visual sensor (listed under cyberware as visible spectrum eye) becomes available at TL8. The following small sensors are available as well:

TL	*Type*	*MCr*
8	Smoke/gas detector	0.001
8	IR motion detector	0.003
8	Magnetic sensor	0.001
8	Radiation sensor	0.002
9	Tactile sensor	0.1*
9	Taste sensor	0.002
10	Ultrasonic motion detector	0.02

*The cost of a tactile sensor is this value multiplied by the MV value of the robot's chassis. If only the tips of arms and other key locations have tactile (touch) sensitivity, multiply this value by 0.1.

All small sensors, both from the cyber chapter and listed above, mass 0.0005 tonnes, consume 0.0005 kl of internal volume and have negligible power requirements.

Step 5: Weaponry

Robots may be equipped with a wide variety of weapons. All of these are covered in the weaponry section of **FF&S** (pages 91+), except for defensive screens, which are covered in the defenses chapter (**FF&S**, pages 56-60). A number of special considerations apply to robot-mounted weapons, however.

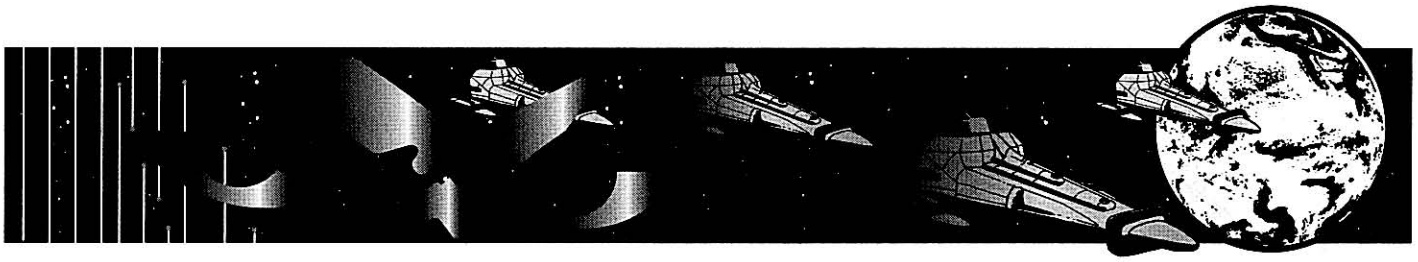
Attachment: Most firing weapons are attached to the torso of the robot, but they may be mounted on an arm instead. All melee weapons must be mounted on arms. An arm may not have weapons mounted on it which mass more than half the lifting capability of the arm, and the mass of the weapon then reduces the lifting capability of the arm by that amount.

Recoil: Excessive recoil force of a weapon may unbalance a robot or damage its chassis. To avoid this, there is an upper limit on total recoil force of installed weapons of one per 100 kg of total robot mass. However, the effective mass of the robot for purposes of recoil is divided by two if a walker suspension is used and by 10 if a lift (air cushion or CG) suspension is used. Note that this may require tinkering with the design later based on final mass of the robot.

Weapon Stabilization: Stabilization gear enables a robot to fire its weapons while moving; the Stabilization Table (see the fire control chapter of **FF&S**) lists the characteristics of stabilization gear at different tech levels. If the weapon is mounted on an arm, the mass of the stabilization gear is not added to the arm.

Weapon Volume: The volume of the installed weapon in kiloliters is equal to its leaded mass in tonnes.

Step 6: Peripherals



The main peripherals for a robot are its arms (if arms are installed). Designers choose the number of arms installed and the volume devoted to each arm, then specify what percentage of the volume of the arm is devoted to articulation and what percentage to power. The volume must be divided between these two design areas in even increments of 10%.

The agility of the arm is the percentage of it devoted to articulation divided by 10. In other words, an arm with 30% devoted to articulation would have an agility of 3.

The Strength of the arm is the total volume in liters devoted to power. When determining the STR attribute of the robot, round this value to the nearest whole number (but never less than 1). When determining lifting ability of the arm, retain the original fractional result. The lifting capability of the arm, in kilograms, is its original calculated Strength multiplied by 50.

CG-lifted robots may usefully mount magnetic grapples as a means of anchoring themselves to a wall or bulkhead. These arms are usually short, feature very little articulation (10% is all that is required), and feature a grasping hand as well as a magnet as a backup for nonferrous surfaces. The lifting capacity of the arm is the maximum mass which it can hold steady. Usually this means that the arm must have lifting strength equal to 10% of the mass of the robot plus 100 or more kilograms, if the robot is also expected to restrain humans.

The mass of an arm in kilograms is its volume in liters multiplied by 2. The price of an arm in credits is its volume in liters multiplied

by 100. The following peripherals may be installed as well:

TL	Vol	MCr
8	Siren	0.0001
8	Paint pellet gun	0.0001
8	Chemical projector	0.0001
8	Strobe/flasher	0.0001
8	Voder/speaker	0.001
8	Odor emitter	0.0005
8	Video display	0.0005
8	Laser cutter/welder	0.008
13	Holodisplay	0.015

All these peripherals mass 0.0005 tonnes, consume 0.0005 kl of internal volume and have negligible power requirements.

Step 7: Power Plant

The robot needs a power plant to provide electrical energy to various subsystems as well as to power the suspension. A variety of power plants are available and are detailed in the power production chapter (Section 8) of **FF&S**.

Grav and air cushion robots also require thrust, as their suspensions serve only to hold them up, not move them forward. The power plant on these vehicles is modified to provide thrust by the addition of propellers or a combustion chamber. The variety of thrusters available is detailed in the sub-light (maneuver) drive chapter (Section 9) of **FF&S**. The optional ducted fan lifters may be used as thrusters on robots.

Fuel tankage for the power plant (and thruster, if applicable) is calculated at this time.

Step 8: Transmission

Robots with a nonlift suspension must have a transmission. The size of the transmission depends on the type of suspension, tech level of the robot and output of the power plant.

Robot Transmissions

TL	Type	Vol	Price
7+	Wheel	0.5	1500
7+	Tracked	0.3	1500
8	Walker	8	10,000
9	Walker	2	2500
10+	Walker	0.4	675

TL: Tech level of availability.

Vol: Volume (in kiloliters) of the suspension per MW of power output.

Price: Price (in Cr) per kiloliter of installed transmission.

Mass: Mass (in tonnes) of the transmission is equal to its volume in kiloliters.

Step 9: Cargo

All remaining volume may be allocated to ammunition stowage, cargo space, ballast or declared waste volume. Waste volume has no effect on the design.

Ammunition stowage has no cost but adds the mass of the ammunition to the loaded mass of the robot.

Cargo volume has no cost but adds to the loaded mass of the robot. Multiply the cargo volume, in cubic kiloliters, by 0.25 to determine the addition, in metric tonnes, to the robot's loaded mass. Tools are usually carried in the robot' internal cargo volume.

Ballast is added by filling the volume with one of the hull materials and calculating its price and mass. Ballast is rarely added to a robot, but may be used to increase its ability to absorb weapon recoil.

DESIGN EVALUATION

Once the design is complete, you need to evaluate it to determine its game ratings.

1. Check Step

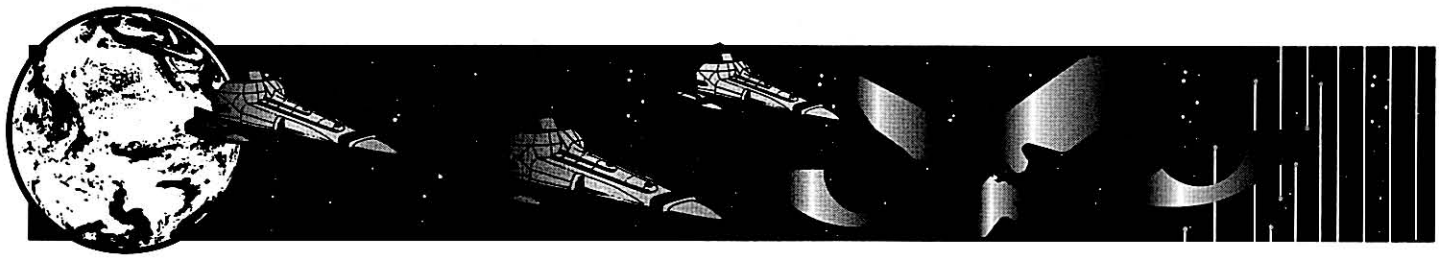
Go back and add up the volume, price and mass of all the components. This is your chance to make sure the robot's internal occupied volume is within what is allowed by the size of the chassis. This step also provides you with a total mass and price.

2. Record Design Features

Most of the evaluation of your design will consist of recording the features already determined by the design, such as armor values, weapon statistics, performance of installed electronics, etc.

Multiply the volume of the original chassis by two and note the result as its transport volume (the space taken up in the hold of a starship or transport vehicle). At the same time, total the price of the robot and its empty and loaded masses. Empty mass is the robot without any ammunition, fuel or cargo. This is essentially the mass of the robot as it comes off the assembly line, and is also what it weighs when being transported. Loaded mass includes a full load of ammunition, fuel and cargo. This is its typical mass when in operation.

Flotation: Divide the chassis volume (in kiloliters) by the robot's loaded mass (in metric tonnes). If the result is greater than 1, the robot floats; if it is 1 or less, the robot will not float.



Suspension Damage Resistance: Compute suspension damage resistance (SDR). For tracked vehicles, this is used as the suspension armor value; for wheeled, walker and air cushion robots, this is used as the critical damage level (see **TNE** page 300). CG robots do not have a suspension damage resistance.

Suspension damage resistance is based on the robot's chassis size in kiloliters as chosen in Step 1. Round fractional results to the nearest whole number, but critical damage levels may never be less than 1.

Tracked SDR=chassis size×0.14.

Wheeled SDR=1×chassis size×0.07.

Air cushion & walker SR=chassis size×0.07.

3A. Determine Ground Movement

Movement of robots with ground contact suspensions (wheels, tracks and legs) is based on top road speeds and cross-country speeds, both of which are determined by the robot's loaded power-to-weight ratio as well as its suspension. For purposes of the power-to-weight calculations, the robot's motive power is the total output of its power plant minus energy used to run other systems (such as electronics, weapons, etc.).

Road Speed

Base road speed in kilometers per hour=5+([MW÷LM]) ×2500).

MW: Robot motive power in megawatts.

LM: Loaded mass of the robot in metric tonnes.

Tracked and wheeled robot modifiers:
Each tech level above 5, +1 kph.
If wheeled, +10 kph.
If light wheeled*, +15 kph.
If legged, ×0.25 kph.

*To qualify for the light wheeled bonus, the robot must be equal to or less than the listed mass (in metric tonnes) for its tech level, as shown on the following table:

Light Wheeled Robots

TL	*Mass*
5	5–
6	10–
7	15–
8	20–
9	25–
10	30–
11	35–
12+	40–

TL: TL of construction

Mass: Maximum weight of a light robot at that tech level.

Cross-Country Speed

Legged robots have the same mobility cross-country as they have on a road. Wheeled robot cross-country mobility depends on the type of suspension used.

Type	*Cross-Country*
Restricted Wheel	0.1
Wheel	0.2
Cross-country wheel	0.4

Type: Suspension type installed on the robot.

Cross-Country: Cross-country speed in kph equals road speed times this multiplier.

Tracked robot cross-country mobility depends on the power-to-mass ratio of the robot.

P/M	*T*
.001-.0039	0.4
.004-.0079	0.5
.008-.0119	0.6
.012-.0159	0.7
.016+	0.8

P/M: Power-to-mass ratio. Divide the robot's motive power in megawatts by its loaded mass in tonnes. Use the line which includes the result.

T: Tracked movement multiplier. Cross-country speed in KPH equals road speed times this multiplier.

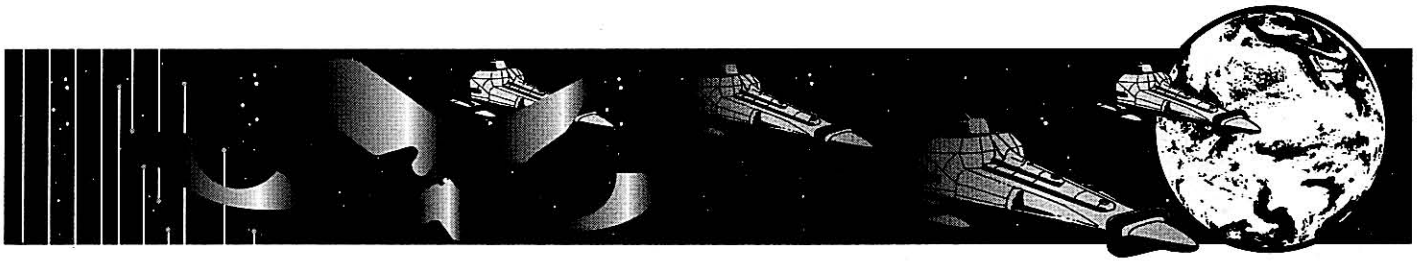
Water Speed: Tracked robots without auxiliary water propulsion and wheeled robots with auxiliary water propulsion have a water speed equal to their road speed multiplied by 0.1. Tracked robots with auxiliary water propulsion have a water speed equal to their road speed multiplied by 0.2.

Combat Move: The combat movement (in meters per turn) is the robot's maximum speed, in kilometers per hour, multiplied by 0.463, rounding the result to the nearest increment of five. This calculation is made separately for road and off-road movement based on the maximum road and off-road speeds. The robot's combat move in the water is equal to its water speed in kilometers per hour multiplied by 1.39.

Travel Move: The robot's travel movement rate (in kilometers per four-hour period) is equal to its combat move (in meters per turn) multiplied by 4.32, rounded to the nearest increment of five.

3B. Determine Lift Movement

Movement of robots with lift suspensions is based on their thrust. The G rating of a lift robot is its total thrust in metric tonnes divided by two times its chassis volume (in kiloliters). Its maximum speed (in kilometers per hour) in an atmosphere is determined as follows:



If G=1 or less, speed=G×3500.
If G=2 or less, but more than 1, speed=3500+(1200(G-1)).
If G=more than 2, speed=4700+(600(G-2)).

Maximum speed cannot be greater than the maximum design speed of the chassis type. For low-performance robots, the maximum design speed is 100 kph. For high-performance robots, the maximum design speed is based on the chassis configuration decision.

Maximum speed for high-performance robots is reduced by drag. Note the total number of drag points from the weapons mounts installed, again both with and without external stores. Reduce the maximum speed by 1% for each drag point.

Cruising Speed: A lift robot's cruising speed is 75% of its maximum speed.

NOE Speed: Only CG robots have an NOE speed. CG

robots have a safe NOE speed equal to the maximum allowed by their terrain-following avionics (40 kilometers per hour if no avionics are installed) or one-quarter of their maximum speed, whichever is less.

Combat Move: The safe NOE combat movement (in meters per combat turn) is equal to the robot's maximum NOE speed (in kilometers per hour) multiplied by 1.39, rounded to the nearest whole number. The high-mode combat movement (in meters per combat turn) is equal to the robot's maximum flight speed (in kilometers per hour) multiplied by 1.39.

Combat movement (in meters per combat turn) for an air cushion robot is maximum speed (kph)×0.463 for road speed, and cruising speed×0.463 for cross-country speed. Cross-country speed is also cross-water speed.

Travel Move: The high mode travel movement rate (in kilometers per four-hour period) for a CG robot is equal to the cruising speed (in kilometers per hour) multiplied by four. The NOE mode travel movement rate (in kilometers per four-hour period) is equal to the safe NOE speed (in kilometers per hour) multiplied by six.

Travel movement for an air cushion robot (in kilometers per four hours) is 4.32 times its combat movement as calculated above.

4. Mental Characteristics

Record the Intelligence (INT) of the brain, the command type available (limited, basic or full), and all programing asset levels. (The asset level of a program is the program skill level plus the INT value of the robot brain.)

Note that the INT value of the robot is also used as its Initiative rating in combat.

5. Firing Characteristics

Record the firing characteristics of each mounted weapon as well as the effects of installed stabilization and fire control.

6. Melee Characteristics

Robots conduct melee attacks with their arms. Since different types of arms may be mounted on a robot, each arm is rated separately for hit chance, unarmed damage and melee weapon.

Hit Chance: The actual Agility of the arm (from 0 to 10) is treated as a skill, and the robot's Intelligence is treated as the controlling attribute in determining the actual chance of hitting with the arm. Agility and Intelligence are added together and used as an asset with either an armed or unarmed melee attack with that arm. Each arm may have a separate hit chance.

Unarmed Damage: This is the damage inflicted by an arm if it hits in an unarmed melee attack. It is calculated by multiplying the STR whole number value of the arm by the AGL value of the arm by 0.1 and rounding to the nearest whole number. However, the value is never rounded down to 0 if it has a fractional value greater than 0.

Melee Weapon: If a melee weapon is mounted on the arm, it is noted here. Its closest equivalent to a human-carried melee weapon is used to help visualize it and rate it. The following additional melee weapon values are noted:

Range: Any melee weapon mounted on an arm displacing 10 liters or more is a "long-range" melee weapon, provided it is the only weapon mounted on the arm. All other melee weapons are short range.

Damage: Improvised weapons of limited lethality (such as screwdrivers or small surgical knives) have a damage value of 1D6–1 or 1D6–2. More lethal weapons have the damage value shown on the melee weapon table in the basic rules. Weapons which rely on STR to augment damage use the STR rating of the arm on which the weapon is mounted.

Note that there are no longer any hit modifiers for weapon type, as this is now built into the agility of the arm mounting the weapon.

7. Damage Capacity

The damage capacity of the robot is the number of hits it takes before being completely wrecked. Multiply the enclosed volume of the robot (in liters) by 0.02 and round to the nearest whole number. The result is the number of hit boxes used in each of the two rows of the NPC hit record. As a reminder that the value is used in each row, it is written twice and separated by a "+."

For example a 250-liter robot would have a damage capacity of "5+5."

8. Maintenance Points

Divide the loaded mass of the robot by the tech level modifier appropriate to the tech level as shown below.

TL	*Maint Modifier*
4-5	2
6-7	3
8-9	4
10-12	5
13-15	6
16+	8

Any robot which has two full-size computers (model St or Fb) installed should divide this result by four to get final maintenance points.

Note that maintenance points may be temporarily increased by environment (see carrier aircraft, **FF&S** page 30, atmospheric performance, **FF&S** page 64, and **TNE** page 309.)

Robots with ground contact suspensions constantly exposed to saltwater use different multipliers for saltwater corrosion: 3 and 1.5 rather than 5 and 2 (page 30).

Appendix I: Design Sequence Upgrades

When designing vehicles for **Striker II** using the design sequences in **Fire, Fusion & Steel**, the **Traveller** technical architecture sourcebook, the following additional guidelines should be used.

GRAV VEHICLE DENSITY AND G RATING

When determining lift vehicle movement, thrust is usually divided by 10 times the vehicle's volume in displacement tonnes to determine G rating. However, this procedure should not be used for very dense grav vehicles, those massing 15.5 or more mass tonnes per displacement ton.

Divide the grav vehicle's loaded mass by its volume in displacement tonnes. If the result is less than 15.5, use the normal procedure described above. If the result is 15.5 or more, G rating is determined by dividing thrust in tonnes by the vehicle's loaded mass in tonnes.

TURRET SIZE

In some cases, designating a turret as a small turret (and therefore requiring its components to take up 10 times their volume) results in the turret being larger than the maximum 10% of vehicle volume. However, when recalculating the turret's volume as a main turret (usually requiring its components to take up 2 times their volume), the turret then falls below the 10% threshold and becomes classified as a small turret again. In such cases, threat the turret as a main turret (using the main turret volume multiplier), but this turret must be the only turret on that vehicle, and the vehicle is then classified as having a *small turret* for purposes of target type in the vehicle damage sequence.

DIRECT ENERGY INPUT LASER HOMOPOLAR GENERATORS

Large direct energy input lasers with trainable focal arrays may be designed for turret mounting in ground vehicles. When fitting these weapons to the vehicles, the laser' homopolar generator need not be placed in the turret, nor have its mass accounted for in the weapon stabilization calculations.

NUCLEAR DAMPERS

The design sequence in **Fire, Fusion & Steel** is based on the assumption that the dampers will be used for space combat, and assumes a rate of fire of one shot per three minutes (10 shots each 30 minutes). Higher rates of fire require a larger power input and a larger nuclear damper. Choose the ground combat rate of fire desired from the table below, and find the volume multiplier that corresponds to it. This volume multiplier is applied to the volume value derived from the Nuclear Damper Design table on page 57 of **Fire, Fusion & Steel.**

The input multiplier is applied to the MW required by the damper from the power plant. Note that this power multiplier is applied *after* the volume multiplier above is applied, and not in combination with it.

If the nuclear damper is to be fitted with weapon stabilization, only its basic mass (before the volume multiplier is applied) is counted against the stabilization requirement.

For example, a TL15 3000km short-range nuclear damper with a ground ROF of SA1 has a volume of 13.2 m^3, draws 10.8 MW, and costs 16.8 MCr (exclusive of beam pointer and workstation). For purposes of fitting weapon stabilization, it has a stabilized mass of 3.3 tonnes (plus its beam pointer mass of 0.15 tonnes).

This procedure may also be used to design starship-mounted nuclear dampers. In this case the increased rate of fire is reflected in –Diff Mods to nuclear damper task rolls in space combat.

Space Cbt ROF	*Ground Cbt ROF*	*Vol Mult*	*Input Mult*	*Space –Diff Mods*
10	1/36	×1	×1	—
30	1/12	×1	×3	—
(50)	N/A	N/A	N/A	–1
60	1/6	×1	×6	–1
90	1/4	×1	×9	–1
(100)	N/A	N/A	N/A	–2
120	1/3	×2	×12	–2
180	1/2	×2	×18	–2
(200)	N/A	N/A	N/A	–3
360	SA1	×4	×36	–3
(400)	N/A	×4	N/A	–4
720	SA2	×8	×72	–4
(800)	N/A	×8	N/A	–5

STABILIZED MISSILE LAUNCHERS

Missile launchers need not be stabilized so long as their sights and control units and designators are, except that missile launchers in turrets do require stabilization.

DRONE MISSILES

Drone missiles are remotely piloted "kamikaze" grav vehicles that use contra-grav lifters for movement through most of their mission, but accelerate to their maximum speed for the final flight into their targets.

Drone missiles are constructed partially as grav vehicles and partially as missiles. Although they are designed based on volume like grav vehicles, they do not require hull material volume or armor to be allocated, and they do not suffer volume losses to waste volume or hull slope. However, although they do not have material allocated for their airframes, like missiles, they are assumed to have airframe structures abstracted into the other materials purchased.

Each drone missile consists of a drone brain, one or more communicators, a warhead, contra-grav lifters, a mode of propulsion (usually a jet engine), batteries to power the lifters and communicators if the propulsion does not meet these needs, and fuel for the propulsion system.

The missile's maximum speed is calculated as if it were a grav vehicle, by dividing its thrust by its volume or mass (see grav vehicle density, above). Its cruising speed is one-quarter this speed, or 200 kph, whichever is less. This is the speed at which the missile always flies until it attacks its target. This speed is considered to be flown at NOE.

Drone Missile Brains

TL	*Mass (kg)*	*Vol (m^3)*	*MCr*	*Agility Bonus*
13	20	0.02	0.1	+3
14	10	0.01	0.1	+4
15	5	0.005	0.1	+5

Drone missiles are launched from Tac missile launchers designed using the normal procedures, although the launcher need not contain any particular control units. Drone missiles do require control stations, usually fitted within the launch vehicle.

A remote drone missile control station consists of a normal workstation, a flight computer of the same tech level as the drone brain, and one each of all communicator types installed on the drone missile. Flight computers and communicators may not be shared among multiple control stations. A single drone missile control stations may control a certain number of missiles per turn depending upon tech level.

Appendix I: Design Sequence Upgrades

TL	Missiles per Turn
9	2
10-11	3
12-13	4
14	5
15-16	6
17-18	7
19+	8

DIRECT FIRE ROCKET LAUNCHERS

Unguided rockets are inherently inaccurate at long ranges. The short and medium range bands for direct fire rockets are calculated normally. However, direct fire rockets have no long or extreme range bands, so may not be fired in direct fire mode at longer than medium range.

PUTTING THE HEAT BACK INTO PLASMA

One of the most consistent requests we receive with respect to the equipment in **Traveller® the New Era** is to increase the effectiveness of high energy weapons. Although we're reluctant to tinker with design sequences and published equipment, the pressure for tougher fusion and plasma rifles has been almost irresistible.

Never let it be said that we don't listen to customers. In fact, the well-known third law of retail sales is "Always listen to your customers." (The first law is "Never kill a customer." The second law is "You break it, you buy it.") So we took a good look at man-portable high energy weapons and concluded that, although they weren't as good as grenade launchers, at least they were real expensive. Hmmm. Perhaps, we decided, there was something to all those annoying complaints after all. The following modifications refer to pages in the **Fire, Fusion, & Steel** high energy weapon design sequences.

Page 67 (Explosive Power Generation)

Change the mass of EPG cartridges to volume x4 (instead of volume x8).

Page 121 (High Energy Weapons)

Range: Short range for plasma guns is now *100 x the square root of pulse energy in Megajoules* (instead of 30 x pulse energy).

Short range for fusion guns is now *150 x the square root of pulse energy in Megajoules* (instead of 50 x pulse energy)

Damage: Damage value (D) is now *30 x the square root of pulse energy in Megajoules* (instead of 11.5 x the square root of pulse energy)

Page 122 (High Energy Weapons)

Penetration: The penetration rating for *both* plasma and fusion guns is now 1-2-10.

Price: The revised component price multipliers for plasma and fusion guns are shown below.

Component	Plasma	Fusion
Firing Unit	600	1000
Support Hardware	600	1000
Gyro-Compensator*	600	600
Inertial Compensator*	1000	1000
Recoil Cradle	25	25
Towing Carriage	2	2
Autoloader	10	10
Gun Shield	1	1

All plasma and fusion weapons appearing in **Striker 2** have been rated according to this upgraded standard. The charts below will allow owners of **Traveller: the New Era, Smash & Grab,** and the **Reformation Coalition Equipment Guide** to update the values for previously published high energy weapons.

				Weight				Price	
Weapon	TL	Pulse	Ammo	Empty	Ldd	BP	Mag	Wpn	Ammo

APPENDIX 1
Standard Socket-Sized Weapons and Defenses for Installation Aboard Spacecraft

Sandcasters for Standard Turret Sockets

TL	Price	Cannisters Carried	Beam Reduction
8	0.6	16	1D6×6
9	0.65	18	1D6×5
10	0.7	20	1D10×5
11	0.75	24	1D10×5
12	0.8	30	1D10×5
13	0.85	35	2D6×5
14	0.9	40	2D6×5
15	1	50	2D10×5

Price: Price of turret in millions of credits; **Cannisters Carried:** Number of sand cannisters carried in turret; **Beam Reduction:** Beam reduction made per successful beam interception

Turret and Barbette Socket Missile Launchers

Type	TL	Missiles	Volume	Weight	Power	Price
Turret	8	2	42	28.4	0.15	0.08
Barbette	8	5	84	70.4	0.15	0.11

Volume: In kiloliters; **Weight:** In tonnes; **Power:** In megawatts; **Price:** In millions of credits (without missiles)

Nuclear Dampers for Standard Turret and Barbette Sockets

TL	Description	Mass	Price	Power
12	Damper Barbette	75.2	1.95	15
13	Damper Barbette	72.2	2.7	9
14	Damper Barbette	60.2	4	6
15	Damper Turret	33.2	4.5	3

Mass: In tonnes; **Price:** In millions of credits; **Power:** In megawatts

Sample Space Missiles for Socket Missile Launchers

TL	Guidance	Yield	Mass	MCr	G-Turns	Hits	Damage	Range	Comm	Sensor	Signatures
8	Controlled	50	7	0.85	10/10	1D6	1/14-43	0	10L	—	+2/+2/+2/+2/+1
9	Controlled	50	7	0.85	12/12	1D6	1/14-43	0	10L	—	+2/+2/+2/+2/+1
11	Controlled	100	7	0.95	12/12	1D6	1/18-56	0	10L	—	+2/+2/+2/+2/+1
12	Semi-Ind.	500	7	2.0	8/8	1D6	1/25-79	0	10L	1P	+4/+3/+4/+3/+1
13	Controlled	200	7	1.15	12/12	1D6	1/21-66	0	10L	—	+2/+2/+2/+2/+1
14	Semi-Ind.	500	7	2.7	8/8	1D6	1/25-79	0	10L	3P	+4/+3/+4/+3/+1
15	Controlled	500	7	1.25	12/12	1D6	1/25-79	0	10L	—	+2/+2/+2/+2/+1

Yield: Warhead yield; **Mass:** In tonnes; **MCr:** Price in millions of credits; **G-Turns:** Number of G-turns of fuel carried (followed by maximum number of G-turns which can be used in a single turn; **Hits:** Die roll for number of hits from the laser; **Damage:** Damage value of each laser hit; **Range:** Absolute range in hexes (0 = same hex only); **Comm:** Type of communicator (L = laser, M = maser, R = radio); **Sensor:** Sensor range (in hexes) and type (R = radar, T = high-resolution thermal, L = ladar, A = active EMS, P = passive EMS); **Signatures:** Missile's signature vs. radar, active EMS, HRT, passive EMS, and fire

Sample Standard Turret and Barbette Socket Lasers

TL	Description	MW	MCr	Mass	Short	Medium	Long	Extreme
10	60-Mj laser turret	1.7	1.56	55	1:1/6-19	2:1/6-19	4:1/3-9	8:1/2-5
11	80-Mj laser turret	2.2	2.08	59	2:1/7-22	4:1/7-22	8:1/6-19	16:1/3-10
11	150-Mj laser barbette	4.2	6.56	119	10:1/10-31	20:1/5-17	40:1/3-8	80:1-4
12	120-Mj laser turret	3.3	0.94	65	4:1/9-27	8:1/9-27	16:1/6-19	32:1/3-9
13	150-Mj laser turret	4.2	0.72	68	1:1/10-31	2:1/10-31	4:1/10-31	8:1/10-31
13	106-Mj laser turret	2.9	1.45	59	10:1/8-26	20:1/6-20	40:1/3-10	80:1/2-5
14	150-Mj laser turret	4.2	0.72	63	2:1/10-31	4:1/10-31	8:1/10-31	16:1/10-31
14	300-Mj laser barbette	8.3	2.16	131	10:1/14-43	20:1/14-43	40:1/8-26	80:1/4-13
15	150-Mj laser turret	4.2	0.86	57	10:1/10-31	20:1/10-31	40:1/10-31	80:1/10-31

MW: Required power input in megawatts; **MCr:** Price in millions of credits; **Mass:** In tonnes; **Short, Medium, Long, Extreme:** Combat performance at these ranges: range in hexes: penetration rating-damage value.

Note: These weapons are the same as those published, with slightly different details, in **Brilliant Lances and first printing** TNE. The differences are due to slightly different rounding conventions from an earlier version of the design sequence. These have been changed in order to give the designer greater control over details of the design. These figures are calculated using the sequences in this book, are official changes, and will be incorporated into future printings of these products. However, players may continue to use the **earlier** values, as the number of different designs and weapons manufacturers in charted space will result in reasonable variation in performance details.

APPENDIX II
1 Using Alternate Technologies

To make alternate technologies easy to integrate in your **Traveller** game, we have provided a suggested baseline tech level of introduction and, where appropriate, indicated the tech levels where additional improvements become available. This constitutes a pre-set "slope" for technological innovation which referees may use as a starting point or alter as they see fit.

To vary the technological underpinnings of your campaign, three methods are available.

1. Alternate Technology: Method number one alters the physical universe by using one or more of the alternate technologies presented in the book, either in addition to or as a substitute for some technology already included in **Traveller**. This method can be as simple as just deleting a piece of projected technology from the mix (such as contra-gravity, jump drive, EAPlaC, HEPlaR, laser focusing, or meson screens) and relying on remaining baseline technologies to fill the gap created.

2. Altered Initial Availability: The tech level at which projected technology becomes available can be moved forward or back. Teleportation is an excellent example of this. Matter transmission is set at such a high tech level of initial vailability that it will effectively play no part in any **Traveller** Imperial Space campaign. By moving its availability to tech level 8, the technological basis of the universe (and its adventuring elements) is changed greatly.

3. Altered Slope: Slope is the rate at which technological change is accomplished. (See page 7 for an explanation of slope.) Raising or lowering the slope has a profound effect on the nature of the gaming universe, and referees building their own universe will almost certainly want to tinker here. A cyber-heavy universe, for example, would probably have a steeper slope on cybernetics than is presented in the chapter as it currently stands, with much more of the equipment available at earlier tech levels. A universe where starship combat is difficult, or limited mostly to large line-of-battle ships, might have a much more shallow slope on laser focussing, as well as other directed energy weapon designs.

You will find that by using these three tools and the design sequences provided in this book, virtually any science-fiction universe can be tailored.

---

6 APPENDIX III
Design Examples

7 Design Example: 7mm TL-10 ACR (ETC)

This will proceeed pretty much in the same order as the design sequence itself. I experimented with several different values for Lcc, E, and Bl until I got numbers for damage and range that I liked (these experimental calculations are not shown here to conserve space). Refer to the design sequence for the meaning of the abbreviations used in the various formulae.

9 PART I: Ammunition Design

Tech Level: 10
Bullet: 7mm
Cartridge Case Length: 30mm
Cartridge Case Type: Necked ETC

Ammunition Evaluation
Length: 44mm
Lan = Lcc+2xd = 30+2x7 = 44
Weight: 12 grams
Wa = AwcLccπr^2 = 0.01x30x3.1416x3.5x3.5 = 11.5454, rounds to 12
Average Muzzle Energy: 4803 joules
Ea = TmCmLccπr^2 = 1.3x3.2x30x3.1416x3.5x3.5 = 4802.8781, rounds to 4803
Price: Cr0.24
Cr = WTm = 12x0.02 = 0.24

Special Ammunition
HE: TL-6+. Price for HE rounds is multiplied by 2: 0.24x2 = 0.48
DS: Tech level 8+. Price for DS rounds is multiplied by 2: 0.24x2 = 0.48
HEAP: Tech level 9+. Price for HEAP rounds is multiplied by 3: 0.24x3 = 0.72
Tranq: Tech level 6+. Price for Tranq rounds is multiplied by 2: 0.24x2 = 0.48

PART II: Weapon Design

1. BARREL
Average Barrel Length: 49 cm
Bla = (Ea+d^2)Rm = (4803+7x7)x0.5 = 49.01021 rounds to 49
Actual Barrel Length: 49 cm (10 to 113)
Type of Barrel: Light barrel
Barrel Weight: 0.98 kg
Wbl = 0.02Lb = 0.02x49 = 0.98
Barrel Price: Cr392
Cr = WbxBtm = 0.98x400 = 392.00
Actual Muzzle Energy: Ball, HE, HEAP, & DS: 4803, Tranq: 2882
E = Ea{1+[0.5(Blp-1)]} = 4803x{1+[0.5x(1-1)]} = 4803
Damage: Ball, HE, HEAP, & DS: 5, Tranq: –1*
Ball & DS: D = $\sqrt{E}$+15 = 69.303679+15 = 4.620245 = 5
HE/HEAP: 7+10 = 17, 17-7 = 10, 10^3 = 1000, 1000+4803 = 5803. $\sqrt{5803}$ = 76.177, 76.177+15 = 5.079 = 5
Tranq: All Tranq round damage = –1 (1D6–1), plus the effects noted in the rules.
Penetration: Ball: 2-3-Nil, DS: 1-2-3, HEAP: 2-2-2, HE & Tranq: Nil.

2. RECEIVER
Receiver Type: Light, self-loading, electrothermal receiver, with selective fire option.
Rate of Fire: 5
Receiver Length: 31 cm
Lr = Tc$\sqrt{Ea}$ = 0.45x69.303679 = 31.186656 = 31
Receiver Weight: 2.702 kg
WrlET = 0.0005Ea+0.3 = 0.0005x4803+0.3 = 2.7015
Receiver Price: Cr875.5
CrEt = (WrAm)+200 = (2.702x250)+200 = 875.5

3. STOCKS

Bullpup stock

Range: Ball: 83, DS: 100, HE/HEAP: 62, Tranq: 30.

SR = √ECmBlm = 69.303679×1.2×1 = 83.164415 = 83

DS: 83×1.2 = 99.6 = 100

HE/HEAP: 83×0.75 = 62.25 = 62

Tranq: SR = √ECmBlm = 53.68426×1.2×1= 64.42111×0.6 = 38.652668 = 30

Blm: Modification to short range for barrel length = 1

Blm = 1+[(Blp-1)C] = 1+[(1-1)×0.75] = 1

4. FEED SYSTEM

Box Magazine: A 20-round detachable box magazine standard issue. This weapon's cartridge is 44mm long, which means that the receiver must be at least 194mm or 19.4 cm to use a box magazine.

Magazine Weight: 0.553 kg

Wm = 0.0006(N+4)Wa = 0.0006×(20+4)×12 = 0.1728, plus 0.019×20 = 0.5528 rounds to 0.553

Magazine Price: 10×0.2592 = 2.592, rounds to Cr3, plus 20×5 = Cr103

5. OPTIONS

Sights: Electronic and laser sights fitted as standard equipment.

Recoil Reduction: Muzzle brake, gyroscopic compensator, and electrothermal action.

Bayonet Lugs: Standard equipment.

Grenade Adapter: RAM shoot-through grenade adaptor fitted as standard equipment.

Flash Suppressor

Length: 1cm per 300 joules of muzzle energy 4803+300 = 16.01 = 16 cm

Weight: .01 kg per cm of length 16×0.01 = 0.16 kg

Price: Cr1 per cm of length = Cr16

6. TINKERING THE DESIGN

None needed.

EVALUATION

Total the various components:

	Length	*Weight*	*Price (Cr)*
Barrel	49	0.98	392
Receiver	31	2.702	875.5
Bullpup Stock	5	0.1	10
Electronic sights		0.2	2000
Laser sights		0.5	300
Gyros. Comp.		0.5	300
Flash Supressor	16	0.16	16
Muzzle Brake (4 cm)		0.2	50
Grenade Adaptor	5	—	50
Bayonet Lug		—	—
Magazine		0.553	103
Weapon, Empty	106 cm	5.895	4096.5
20 rounds 7×46mm		0.24	4.8
Weapon, Loaded	106 cm	6.135	4101

Determine bulk:

Bulk: 106+15 = 7.06 = 7

and proceed to determining recoil

Recoil:

Single shot:

R = {[(0.15√E)+Ww]+Em}Rcm

Ball, HE, HEAP, & DS: R = {[(0.15×69.303679)+6.135]+2}×0.23 = 0.849 = 1

Tranq: R = {[(0.15√E)+Ww]+Em}Rcm={[(0.15×53.684262) + 6.135]+2}×0.23 = 0.762 = 1

R: Recoil number

E: Muzzle energy (in joules) = Ball, HE, HEAP, & DS: 4803, Tranq: 2882

√E = Ball & DS: 69.303679, Tranq: 53.684262

Ww: Weight, in kilograms, of weapon (loaded) = 6.135

Rcm: Recoil compensator modifier = 0.6×0.5×0.75 = 0.23

Em: Modifier for high muzzle energy. 2501-5000 joules = 2

Bn: Number of shots in the burst.

Burst:

R = ({[(Bn+2)(0.15√E)]+Ww}+{[Bn+2]Em})×Rcm

Ball, HE, HEAP, & DS: R = ({[(5.0+2)×(0.15×69.303679)] + 6.135}+ {[5+2]×2})×0.23 = 2.124 = 2

Tranq: R = ({[(5.0+2)×(0.15×53.684262)] + 6.135}+ {[5+2]×2})×0.23 = 1.904 = 2

Finally, we note the weapon's statistics in usable form

7×46mm ETC TL-10 ACR

TL: 10

Ammo: 7×46mm ETC (TL-10)

Weapon Weight: 6.135 kg loaded, 5.895 empty

Magazine Weight: 0.793 kg loaded, 0.553 kg empty

Magazine Price: Cr3

Damage: Ball, HE, HEAP, & DS: 5, Tranq: –1*

Penetration: Ball: 2-3-Nil, DS: 1-2-3, HEAP: 2-2-2, HE & Tranq: Nil.

Range: Ball: 83, DS: 100, HE/HEAP: 62, Tranq: 30.

1 2 3 4 5 6 7 8 9 10 11 12 13 14

Round	ROF	Dam	Pen	Blk	Mag	— Recoil — SS	Brst	Rng
7×46mm Ball	5	5	2-4-Nil	67	20	1	2	(83) 103
7×46mm DS	5	5	1-3-Nil	7	20	1	2	(100) 120
7×46mm HE	5	5	Nil	7	20	1	2	(62) 71

7×46mm Tranq-9	10	44	12	2882	0.48

Design Example: TL-13 Plasma Cradle Gun (Vehicle-Mounted)

SPECIFICATIONS

TL: 13
Pulse Power: 12 Mj
Fire Control: Comes with basic optic sights. TL 12 ballistic computer added. (Mass = 0.4 tonnes. Price = MCr0.1. Fire Control rating = +4)
Mount: Cradle (for vehicle mounting)
Cartridge: Tech level 12 Plasma Pulse Cartridge, 12 Mj
Volume: (12×.0003=) .0036 cubic meters
Price: (12×.000025=) MCr.0003 (Cr300)
Mass: (.0036×8=) .0288 tonnes (29 kg)
Radius: .058 meters (58mm)
Dimensions: 116×348mm

WEAPON DESIGN

MASS
Firing Unit: (12×4=) 48 kg
Support Hardware: (12×6=) 72 kg
Fire Control (from above): 40 kg
Recoil: (12×20=) 240 kg
Autoloader: (30×29=) 870 kg
TOTAL: 1270 kg

GUN CREW
1 (since it is vehicle-mounted with an autoloader)

RANGE
Short Range: (12×30=) 360
Medium Range: (360×2=) 720
Long Range: (360×4=) 1440
Extreme Range: (360×8=) 2880

DAMAGE VALUE
Damage: (11.5×3.46=) 39.79 (39)

PENETRATION
Rating: 1-2-10
Value: 39-19-3

RELOADING
Reload Time: (.3×12+3=) 1.2 (1)
Rate of Fire: (2)

PRICE
Firing Unit: (48×2500=) Cr120,000
Support Hardware: (72×2500=) Cr180,000
Fire Control (from above): Cr100,000
Recoil: (240×100=) Cr24,000
Autoloader: (870×10=) Cr8700
TOTAL: Cr432,000

SET-UP
None (vehicle-mounted)

VOLUME
Firing Unit: (.048×0.5=) .024
Support Hardware: (.072×0.5=) .036
Fire Control: (.040×1=) .040
Recoil: (.240×1=) .240
Autoloader: (.870×1=) .870
TOTAL: 1.210 cubic meters

RECOIL
None (cradle-mounted)

BULK
None (cradle-mounted)

Design Example: TL-13 Grav Tank

Step 1–Chassis: A 7-ton (98 kiloliter) chassis is selected in a fast subsonic configuration. It uses superdense armor and has an overall level of protection of 4 (0.3cm of armor). This is thickened to 0.39 (AV 5.4) on the sides, 0.3 (AV 8) on the top, and 2.15cm (AV 30) on the front. The sides are given a moderate slope (AV = 5.4×1.5, or 8) and the front is given a radical slope (AV = 30×2, or 60).

Component	*Vol*	*Mass*	*Power*	*Area*	*Price*
Chassis 7	(98)	—	—	—	—
Fast Subs. config.	4.9	—	—	(126)	—
Armor: 0.3cm SD (AV 4)	0.6	9	—	—	8568
Top: + 0.3cm (AV 8)	0.15	2.25	—	—	2142
Side: + 0.09cm (AV 5.4)	0.027	0.405	—	—	385.5
Front: + 1.85cm (AV 30)	0.37	5.55	—	—	5283.6
Front rad. slope (AV 60)	19.6	—	—	—	—
Side, mod slope (AV 8)	19.6	—	—	—	—
High-Efficiency CG	2.1	1.4	0.7	—	210,000

Step 2– Suspension: High-efficiency CG lifters are used.

Component	*Vol*	*Mass*	*Power*	*Area*	*Price*
High-Efficiency CG	2.1	1.4	0.7	—	210,000

Step 3– Control Systems: The vehicle uses tech level 13 holographically linked controls and has both flight avionics and terrain-following avionics. It also has two flight computers (main and backup).

Component	*Vol*	*Mass*	*Power*	*Area*	*Price*
TL-10 Flight Avionics	0.001	0.001	0.1	—	250,000
TL-13 Terrain–Follow. Avn.	0.1	0.02	—	—	15,000
Model 13 Flight computer	0.9	0.18	0.045	—	4000
Backup computer	0.9	0.18	0.045	—	4000

Step 4– Life Support: The vehicle is pressurized to allow operations in hostile environments.

Component	*Vol*	*Mass*	*Power*	*Area*	*Price*
Basic Life Support	0.49	0.49	0.0098	—	29,400

Step 5–Electronics: The vehicle has a 300-kilometer radio for broadcast communications and a 3-km laser communicator for secure tacnet communication. For sensors, it mounts a 3-km active EMS array and a jammer of equivalent performance and a 30-km passive EMS sensor.

Component	*Vol*	*Mass*	*Power*	*Area*	*Price*
300-km radio (TL 12)	0.0001	0.0002	0.01	0.1	5000
30-km laser comm (TL 12)	0.004	0.008	0.005	1	5000
3-km active EMS (TL 12)	0.1	0.2	0.5	0.2	200,000
3-km active EMS jammer	0.1	0.2	1.0	0.2	400,000
30-km passive EMS (TL12)					
Processor	0.01	0.02	0.001	—	20,000
Antenna (TL 13)	0.0005	0.0005	—	0.01	500

Step 6–Weaponry: The tank mounts a 12-Mj plasma cradle gun in the turret and both a 7.5mm machinegun and 3cm laser coaxial with it (and operated from a single gunner's station). The plasma gun is that designed in the example provided earlier in this appendix; the laser and machinegun are taken from the equipment list in the basic game. All volumes are doubled because of placement in the turret. (At tech level 7, volumes would be tripled; at tech level 6, they would be quadrupled). Note that the mass and volume of the plasma gun includes a ballistic computer and autoloader. The weapon mount is stabilized. 400 PPC for the plasma gun and 3000 rounds of ammunition for the machinegun are carried as well. 1

Component	*Vol*	*Mass*	*Power*	*Area*	*Price*
12-Mj Plasma Cradle Gun	2.42	1.27	—	—	432,000
7.5mm machinegun	0.017	0.0085	—	—	1200
3cm coaxial laser rifle	0.01	0.005	—	—	4000
Stabilized turret mount	0.2	0.1	—	—	50,000
400 x PPC	2.88	11.52	—	—	—
3000 rounds 7mm	0.09	0.09	—	—	3600

Step 7–Power Plant: The vehicle has a 3.3 MW fusion power plant and a HEPlaR chamber to convert 0.8 MW of power to thrust. Fuel tankage for one year of reactor operation and 20 hours of thrust are included as well. 4

Component	*Vol*	*Mass*	*Power*	*Area*	*Price*
TL 13 3.3 MW fusion reactor	1.1	3.3	(3.3)	—	340,000
0.8-MW HEPlaR Thruster (16tt)	0.08	0.08	0.8	—	800
Reactor fuel	0.11	0.0077	—	—	—
Reaction mass	4	0.28	—	—	—

Step 8–Crew: The vehicle has a driver (in the hull), a commander (turret), and gunner (turret). There is also a passenger seat (adequate) installed in the hull. Note that workstation volumes in the turret are doubled.

Component	*Vol*	*Mass*	*Power*	*Area*	*Price*
2 turret workstations	14	0.4	—	—	4000
1 hull workstation	3.5	0.2	—	—	2000
1 passenger seat	3.5	0.2	—	—	100

Step 9–Cargo: Most remaining volume is devoted to cargo space.

Component	*Vol*	*Mass*	*Power*	*Area*	*Price*
Cargo	16	4	—	—	—

EVALUATION

DESIGN FEATURES

See above.

Fuel consumption is 0.11 kl of fuel per year for the reactor and 0.2 kl of fuel per hour as thruster reaction mass. On-board reaction mass is sufficient for 20 hours of movement; the reactor requires refueling once per year.

MOVEMENT

Thrust: 0.8 MW = 16 tonnes

Gs: 16÷70 = 0.2286 Gs

Max Speed: 0.2286×3500 = 800.1 kph (limited to 800 by airframe type)

Heavy turret is 10% of volume (5.617 + 58.8 kl after sloping), reducing speed by 10% to 720 kph

Cruising Speed: 720×0.75 = 540 kph

NOE Speed: 720×0.25 = 180 kph (limited to 170 kph by TL-13 avionics)

Combat Move: 24 (NOE), 100 (high mode)

Travel Move: 1020 (NOE), 2160 (high mode)

MAINTENANCE POINTS

41.7659÷6 = 6.96 (rounded to 7)

DESIGN RECAPITULATION

9 **Sample Design: Tech Level 14 Socket Barbette Turret**

The following example explains the design of the standard TL-14 socket laser barbette as seen in Appendix 1, and mounted on the famous *Gazelle*-class close escorts.

10 **1. Tech Level**

Laser is TL 14, and will be tunable. This will allow the laser to have the greatest possible utility as it will be installed in standard sockets aboard a wide variety of vessels.

11 **2. Gravitic Focusing**

The laser is for the Imperial Space campaign, so uses gravitic focusing.

12 **3. Focal Array**

In order to attain maximum range at all of the tunable wavelengths, the laser's focal array will use the full diameter of the standard barbette socket.

3A. Standard Socket Mounted Lasers

13 From the table, the diameter used for the focal array is 4.5 meters.

3B. Bay-Mounted Lasers

Does not apply.

14 **4. Discharge Energy**

Discharge energy (DE) will be 300 megajoules.

Because the turret is intended for installation on a starship, it is built with a heavy focal array.

The focal array has a diameter of 4.5 meters, which gives a radius of 2.25 meters. Surface area is therefore:

$3.1416 \times (2.25)^2 = 15.9$, rounded to 16.

Focal array volume multiplies the surface area by the discharge energy (300) and by the tech level volume multiplier, which for a TL-14 heavy focal array is 0.001.

$16 \times 300 \times 0.001 = 4.8$ cubic meters.

Mass is 4.8 tonnes, and price for a heavy focal array is volume times 0.2 or $(4.8 \times 0.2 =)$ 0.96 MCr.

Because gravitic focusing was chosen in Step 2 above, the laser's efficiency is automatically 20%. Input energy is calculated from the discharge energy (300) as follows:

$300 \div 0.2 = 1500$ megajoules.

5. Laser Performance Rating

5A. Non-Gravitic Focused

Does not apply.

5B. Using Gravitic Focusing

The FA diameter established above is 4.5 meters.

1. 4.5 meters $\times$ 10 = 45 decimeters
2. The focal modifier for a TL-14 heavy focal array is $F = (6D)^2$

$(6 \times 45)^2 = 72{,}900$

3. 72,900 ÷ 10 = 7290, which is the laser's adjusted focal value F.

4. We will calculate two effective ranges here for our tunable laser: its best range, by tech level, which is far ultraviolet (FUV: wavelength of 1000Å), and also its range in the visible band (VL: 5000Å), which is usually the best wavelength for planetary bombardment.

These equations both use the formula F × range factor = effective range, where the FUV range factor from the Tunable Lasers table is 100, and the VL range factor is 20.

Effective range in FUV is 7290 × 100 = 729,000 kilometers, or (729,000 ÷ 30,000 =) 24.3 space combat hexes/range bands.

Effective range in VL is 7290 × 20 = 145,800 kilometers, or (93,300 ÷ 30,000 =) 4.86 space combat hexes/range bands.

5C. Tunable Lasers

We have already calculated one of our available tunable wavelengths immediately above.

5D. Atmospheric Performance

We will now calculate ranges in a standard atmosphere at FUV and VL wavelengths.

For FUV, we multiply the range of 729,000 by 0.01 to get an atmospheric effective range of 7290 km.

For VL, we multiply the range of 145,800 by 0.1 to get an atmospheric effective range of 14,580 km.

The selection of visible tuning was significant, as it has twice the atmospheric range as far ultraviolet.

Planetary Bombardment: To see this effect, we will examine the example of this laser conducting planetary bombardment from a range of 2 hexes.

In FUV, 2 ÷ 0.01 = an atmosphere adjusted range of 200 hexes, far beyond the laser's effective range.

In VL, 2 ÷ 0.1 = an atmospheric adjusted range of 20 hexes, within the laser's effective range. We will find the laser's damage and penetration performance at these ranges below.

6. Define Short Range

6A. Large (Non-Hand-Held) Lasers

Because this is a large (heavy focal array) laser, it will be fitted with a beam pointer. Since its effective range (24.3 hexes) is well in excess of any beam pointer, we will select the best available beam pointer from Section 14, the 300,000 km/10 hex model. At TL 14, it has a volume of 6 cubic meters, a mass of 6 tonnes, and a price of (6 × 0.1 =) 0.6 million credits.

Our laser's short range is therefore 300,000 km or 10 hexes.

6B. Small Arms (Hand-Held) Lasers

Does not apply.

7. Laser Combat Ratings

7A. Combat Range Bands

Because our laser is designed for spacecraft mounting, we will calculate ranges in space combat hexes/range bands.

Our laser has a medium range of 10 × 2 = 20 hexes.

Our laser has a long range of 10 × 4 = 40 hexes.

Our laser has an extreme range of 10 × 8 = 80 hexes.

7B. Damage Value

In order to calculate damage values, we must first calculate the laser's intensity at its four combat ranges using $I = DE (1 + R^2)$.

Value for R at short range is (10 ÷ 24.3 =) 0.412 which becomes 1.

Value for R at medium range is (20 ÷ 24.3 =) 0.823 which becomes 1.

The value for R at medium range is (40 ÷ 24.3 =) 1.64609 which is rounded to 1.65 (nearest 0.01).

The value for R at extreme range is (80 ÷ 24.3 =) 3.29218 which is rounded to 3.29.

At short range, the laser has an intensity of $300 \times (1 + [1]^2) = 300$

At medium range, the laser has an intensity of $300 \times (1 + [1]^2) = 300$

At long range, the laser has an intensity of $300 \times (1 + [1.65]^2) = 110.2$

At extreme range, the laser's intensity is $300 \times (1 + [3.29]^2) = 27.72$

With the four range intensities, we can now calculate damage values.

Damage value at short range is $2.5 \times \sqrt{300} = 43$

Damage value at medium range is $2.5 \times \sqrt{300} = 43$

Damage value at long range is $2.5 \times \sqrt{110.2} = 26$

Damage value at extreme range is $2.5 \times \sqrt{27.72} = 13$

7C. Penetration Rating

These calculations are made using the same intensity values derived in 7B above.

Inverse penetration rating at short range is $0.8 \times \sqrt{300} = 13.85$ rounded to 14, inversed = $^1/_{14}$

Inverse penetration rating at medium range is $0.8 \times \sqrt{300} = 13.85$ rounded to 14, inversed = $^1/_{14}$

Inverse penetration rating at long range is $0.8 \times \sqrt{110.2} = 8.4$ rounded to 8, inversed = $^1/_8$

Inverse penetration rating at short range is $0.8 \times \sqrt{27.72} = 4.21$ rounded to 4, inversed = $^1/_4$

7D. Personnel Damage Dice

Because this is a space combat weapon, and would only hit personnel after penetrating a starship hull, personnel damage dice should only be calculated on a case-by-case basis on remaining damage value.

8. Power Source and Rate of Fire

8A. Direct Electrical Power

This laser will be powered by direct electrical power, and will require a homopolar generator of 1500 × 0.04 = 60 cubic meters. The HPG masses (60 × 2 =) 120 tonnes, and costs (60 × 0.01 =) 0.6 million credits.

Rate of Fire: The laser will be powered to a rate of fire of 10 shots per 30-minute space combat turn. This rate of fire does not require an increase in focal array volume.

Power Input: (10 × 1500) ÷ 1800 = 8.33 megawatts.

8B. Chemical Laser Cartridge

Does not apply.

9. Crew

The barbette will be crewed to allow local control and therefore requires a normal workstation. The Controls chapter (Section 4) shows that a normal workstation has a volume of 7 cubic meters and a mass of 0.2 tonnes, and at TL-14 costs 0.002 million credits.

10. Laser Furnishings and Supporting Hardware

Does not apply.

11. Physical Characteristics

11A. Volume

Focal array plus beam pointer plus homopolar generator plus workstation total (4.8 + 6 + 60 + 7 =) 77.8 cubic meters, well within the 84 cubic meter restriction for standard barbette sockets.

11B. Mass

Focal array plus beam pointer plus homopolar generator plus workstation total (4.8 + 6 + 120 + 0.2 =) 131 tonnes.

11C. Price

Focal array plus beam pointer plus homopolar generator plus workstation total (0.96 + 0.6 + 0.6 + 0.002 =) 2.162 million credits (MCr).

11D. Power Requirements

From Step 8A: 8.33 megawatts (MW).

11E. Surface Area

From standard barbette socket table and Step 4, 16 square meters.

11F. Bulk

Does not apply.

11G. Recoil

None.

11H. Combat Performance

See final listing of the weapon is seen in Appendix 1 on page 153.

FIRE, FUSION, & STEEL™:

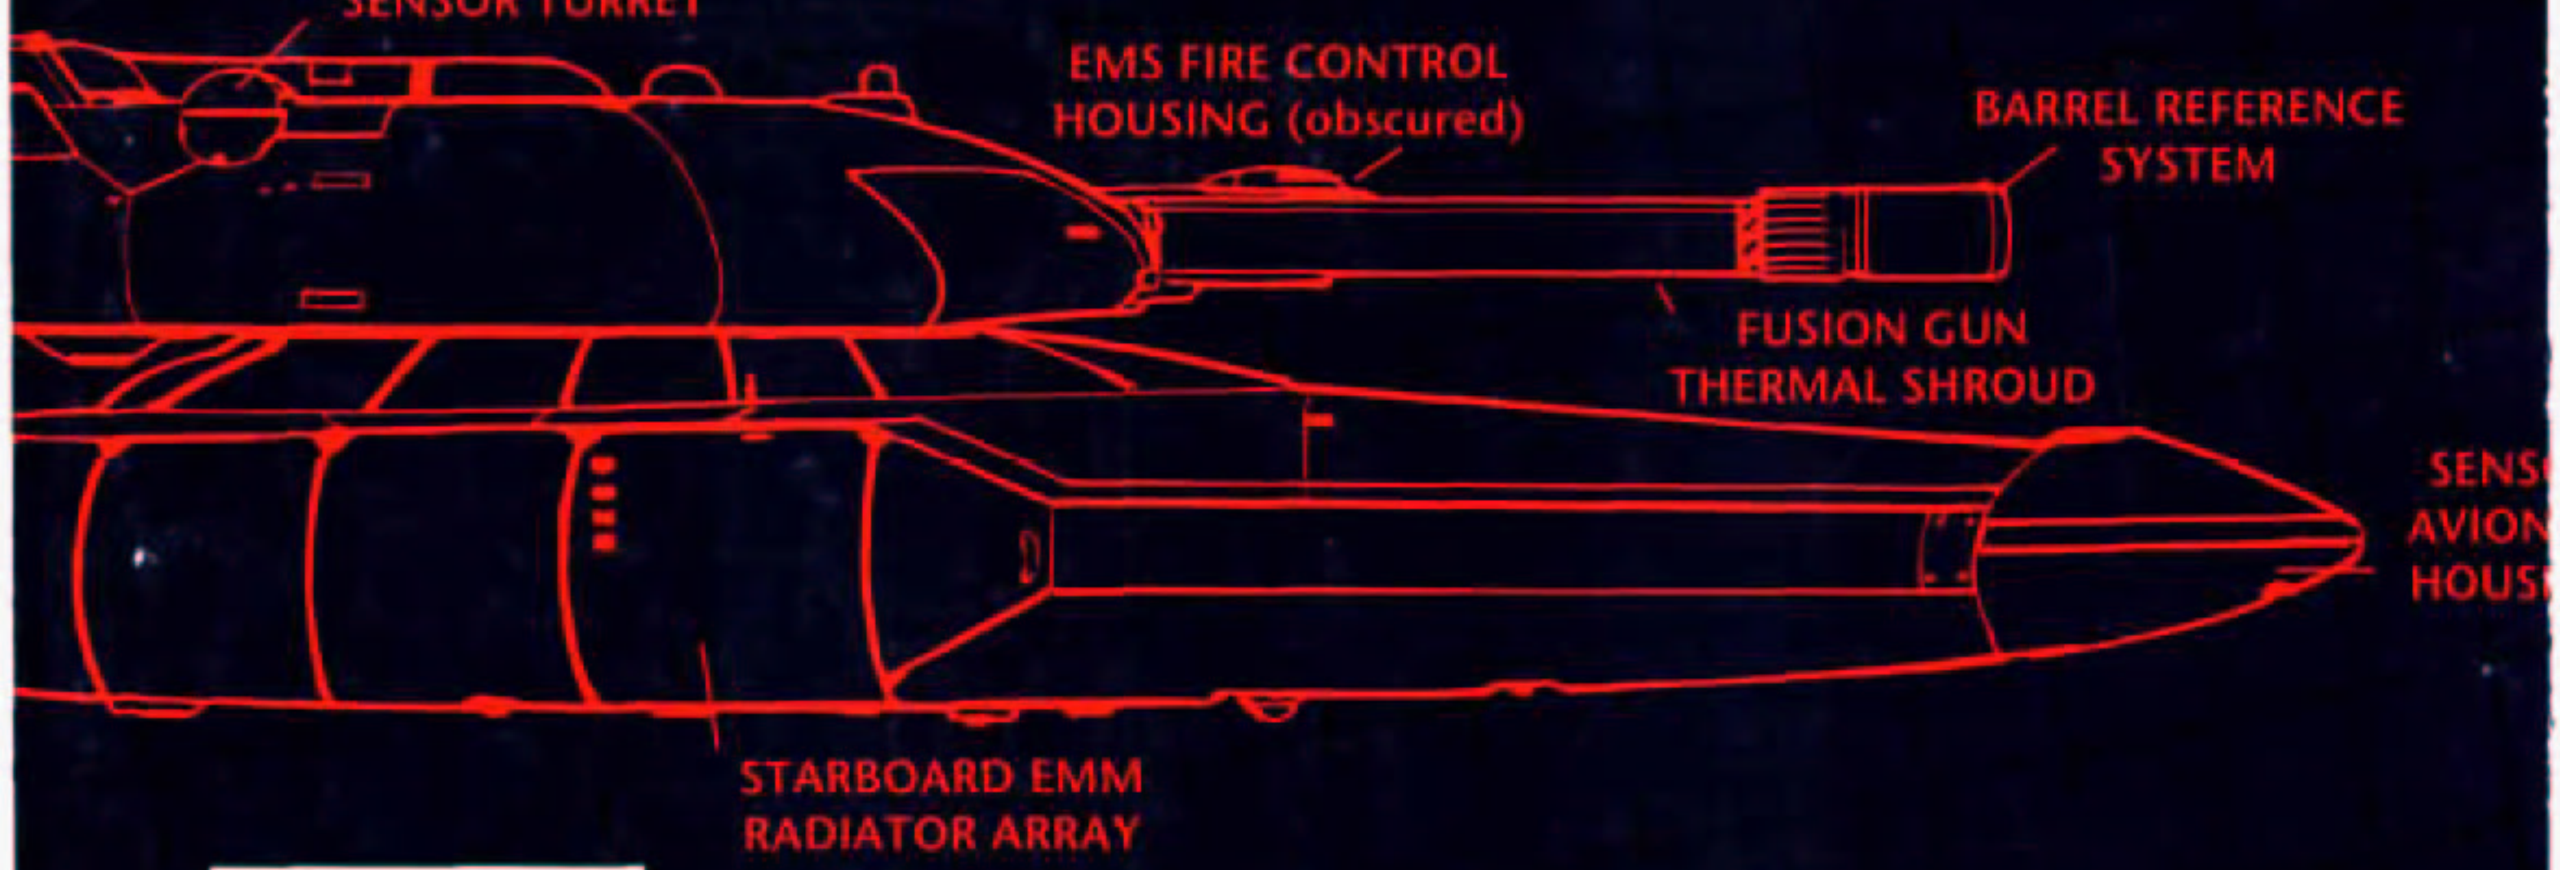
The Traveller Technical Architecture...

puts you in control of your science fiction game in ways that no other product ever has!

Science fiction is about diversity, the unusual, and pressing the cutting edge of science. It' not suited to simple lists of equipment that limit play. Each different world's environment call for slightly different approaches to transportation, communication, and ever weaponry. You need rules to design whatever equipment you need, and as many diferent variations of it as your players find uses for. More than that, you don' need jargon and double-talk; you need to understand enough of the science behind the equipment that you can see how it works, understand its limitations and make the game come alive.

Fire, Fusion, & Steel has all of that and more. Starships, aircraft, and vehicles, i almost infinite variation, are at your command, from fusion-power grav tanks to advanced technology lighter-than-air ships, from gigantic armored star cruisers to delicate ornithopters.

Pick your power plants from a selection that ranges from primitive steam engine to matter-antimatter annihilation, with side excursions to solar power, batteries explosive power generation, or even cold fusion.



Tired of just playing with jump drives? Tailor your campaign around a wide selection of FTL options, from natural wormholes to stargates, stutterwarp, o hyperspace drives. Or if FTL is too advanced for you, conquer space the hard way with Bussard hydrogen ram jets or Daedalus thermonuclear pulse drives.

The cybernetics chapter alone has dozens of entries and provides a rich basis for adding cybernetic enhancement to any science fiction game.

Weaponry isn't slighted either. Rules and supporting data enable you to design small arms conventional cannons, gauss weapons, plasma and fusion weapons, lasers, particle accelerators meson guns, missiles, and more. Or counter them with reactive armor, electrostatic armor, meson screens, or nuclear dampers.

Fire Fusion, & Steel gives you unprecedented control over your campaign environment by not only providing a variety of design rules (and explaining the physics behind then in layman's terms), but also by covering a wide variety of technologies not part of the core Traveller™ game universe. It is a sourcebook on universe building for any science fiction referee, and an indispensable reference work on future technology.

Other people give you catalogues of future equipment.
We've given you the factory.

- Atmospheric Composition 90

9: Design Sequences 92
- Black Powder Firearm Design 92
- Wagons 95
- Bow Weapon Design 96
- Black Powder Cannon Design 97

10: Equipment 100
- Smoothbore Flintlock Musket & Rifled Musket 101
- Blunderbuss & Double Blunderbuss 102
- Blunderbuss Pistol & Horse Pistol 103
- Wall Gun & Flintlock Rifle-Musket 104
- 13.5cm & 9.5cm Field Guns 105
- 7.5cm Rifled Field Gun & 12cm Howitzer 106
- Tukera Freighter 107
- *Hercules*-class Bulk Carrier 108
- Frontier Transport 109

CHAPTER 1: INTRODUCTION

World Tamer ('wərld tām-ər) *1. A member of a team of professional explorers, technicians, and social engineers sent to a low-technology world with the mission of advancing the world's technological and productive capacities and reintegrating that world into the interstellar community. 2. A professional, experienced leader of a colonizing expedition sent to settle an unpopulated or very low population primitive world with colonists from a relatively high tech mother world. 3. Any individual working to uplift, colonize, or civilize an isolated, uninhabited, or primitive world.*

The **World Tamers Handbook** is a **Traveller: The New Era** sourcebook as well as several adventure campaigns built around the theme of rebuilding shattered worlds near the Reformation Coalition (or other surviving pockets of civilization). In either role, it is intended for use with GDW's **Traveller: The New Era** roleplaying rulebook. **Traveller: The New Era** is referred to as "TNE" for simplicity throughout this book. Other required materials are at least one 10-sided die, at least two six-sided dice, and pencils and paper. A calculator is highly recommended. The **Fire, Fusion, and Steel** technical architecture sourcebook will also be necessary in conjunction with some of the design sequences in this book. **Brilliant Lances**, the TNE starship combat boardgame, may also be used to resolve space combat scenarios fought during the adventure campaign.

Source Book

As a source book, **World Tamers Handbook (WTH)** provides referees with expanded or new information on the following subjects:

- A playable planetary economic model, including agricultural, raw materials, and industrial components, fully interlinked with the characteristics of planetary environment
- Star and planetary system generation and detailing
- Expanded planetary survey rules that mate with the planetary economic model, allowing players to seek out worlds suited for habitation and development
- Rules for acclimatization to new environments
- Battalion-level mass combat rules, allowing the resolution of large-scale combat in **Traveller**
- Archaic weapons design sequences including black powder small arms, black powder cannons, and bows
- New equipment based on the new design sequences plus three new starships suited for colonization missions

As a sourcebook, **World Tamers Handbook** allows you to create a world and build a civilization on it from scratch.

Campaigns

World taming is a big, complex topic for a **TNE** campaign. Your players will be shaping the destiny of a world as they interact with local NPCs and try to convince them of the benefits of civilization, or as they lead a group of colonists on a raw frontier world. World tamer campaigns can be played on various levels of detail, from high-level planning and decision-making to low-level roleplaying. Often, a given campaign will shift from level to level as the situation and the players' interests warrant. For example, worlds will be surveyed and the world tamer team can meet and interact with animals or indigenous inhabitants on a day-to-day, one-on-one basis. This low level campaign action may shift to a higher level with progress occurring month to month as the players administer the world-taming effort as the leaders of a colonization team. However, sudden events, such as an attack by a hostile power, political unrest, or natural disasters, may shift the campaign focus back to the low, person-to-person level as a crisis is resolved with work, negotiation, or combat.

World Tamers Handbook offers three campaign scenarios and material to create a myriad of others. The three scenarios are the Survey adventure, Bootstrap campaign, and Colony campaign. These scenarios use different combinations of the material presented in the **World Tamers Handbook**, and referees will need to make a number of decisions before beginning play. Depending on the desired mix of high and low level play and the amount of pre-generated background that will be needed, referees will use this handbook in one of several ways. This organizational material is presented, broken down by scenario type, beginning at the top of the facing page.

CHAPTER 2: ORGANIZING YOUR CAMPAIGN

Campaign (kam 'pān) n. 1. A series of military operations with a particular objective in a war. 2. A series of organized, planned actions for a particular purpose.

CHOICES

Before beginning your World Tamers adventure you must make a number of choices to set a background tone. The choices you make depend on your experience as a **Traveller** referee and the experience and interests of your players. Are the members of your group novices interested in both learning the **Traveller** roleplaying game system and having a rousing good time? Then hire them on as security specialists for a bootstrap or colony expedition. Are your **Traveller** players really experienced and the kind that would rather use Persuasion, Act/Bluff, and other Charisma-related skills to convince low tech indigenous farmers that it's better to use an iron plow to till a field than an iron spear to kill a man? Then have them lead a bootstrap expedition into the Primary AO, uplift friendly primitives, and help them protect themselves from hostile neighbors.

Read the campaign possibilities in this book and weigh them against the interests of your players. Many of the campaign themes are fairly cerebral, with such mundane but important activities as establishing a local economy or determining whether available food supplies will last until the next crop comes in, and if not, what to do about it. Not as glamorous as a firefight, but just as much a matter of life and death. More advanced players might prefer playing this type of role. Other players, however, might prefer playing the cops on a colonial expedition who keep order and solve crimes on the wild frontier.

LEVELS

The term "levels" describes the degree of involvement of players with NPCs in a campaign. There are basically two approaches to playing a world tamer campaign (or, indeed, any roleplaying campaign): low level and high level, but by combining elements of these two approaches, a referee can establish any level in between, based on the needs of the campaign action and the interests of the players.

Low: Low-level roleplaying places the players down in the campaign interacting with NPCs and the referee in "real time," one-on-one. Time is measured in seconds in a firefight, minutes during personal interaction or perhaps in four-hour increments if the players are travelling overland. In a high-level campaign, player characters may order their troops into battle, but in a low-level campaign, the PCs are the ones pulling the triggers.

High: High-level roleplaying pulls players back from direct interaction on a roleplaying level. The players are are high-level decision makers, and the time scale is often stretched out into weekly or monthly increments. For example, players examining the resources of a world to determine how best to create a productive society there are engaged in high-level roleplaying. Or, in another vein, in a low-level campaign, the PCs are concerned about surviving through the current firefight. In a high-level campaign, the PCs are concerned about planning and supplying campaigns, where to send the army next if the battle is won, or what to do if it loses? Which of these levels is most interesting? That depends on the interests of the players.

	Low Level	*High Level*
Game Time Increments	Daily, Hourly	Monthly
Character Involvement	Personal	Abstract
Characters	Hired Tech/Security	Team Leaders/Technical Experts
Suited For	Action/Adventure/Quick Rewards	Planning/Analysis/Long Term Results
Player Experience	Novice to Experienced	Experienced to Expert
Referee Experience	Novice to Experienced	Expert

High-Low Interface: Both levels of roleplaying are found in many campaigns, and this presents a challenge to the referee. Even the most cerebral colony campaign can be punctuated by low-level play as unexpected events happen and crises have to be handled. In a sense, a high-level campaign can be thought of as a "scenario generator" for low-level roleplaying as important decision points occur.

The challenge to the referee is to be able to shift rapidly from the general, in which the players manipulate economic inputs on a monthly basis, to the specific, in which they could use their skills to stop a disease, persuade an unruly rebel, or defeat an invading enemy army. This requires the referee to have a clear understanding of the world that is being modelled: what individual-level, one-on-one adventures will have an input visible up at the high level?

This is easiest if the referee has planned when to shift the campaign from high to low level, but there may also come times when the players decide that they want to "get their hands dirty" and go out and do some world taming on their own.

Perhaps this involves appearing before a gathering of disgruntled citizens and attempting to persuade them to work a little harder, even though there's not much food right now. Perhaps it means hunting down and killing a dangerous local animal that has been preying on livestock. These details will be related to rolls on the various random events tables, and to the referee's vision for the course of the campaign, but these high-low transitions will clearly require a deft and skillful touch by the referee. Details and suggestions for these transitions are presented in the Bootstrap and Colony chapters.

CAMPAIGNS

The three adventure/campaigns presented in this book focus on different activities, high/low level flavor, and material elsewhere in this book that they will draw on.

Survey

Surveying worlds near the Reformation Coalition is usually the responsibility of the Reformation Coalition Exploratory Service, which provides data used to plan bootstrap and colony operations. However, the RCES often uses free-lancers for survey and intelligence gathering missions, and here is where the PCs come in. RCES may recruit them to survey one or more star systems and their planets. Or, they may independently find a world suitable for a bootstrap operation or colonization, survey it, and sell the information to the RCES. A survey can be an adventure in itself, or it can be the beginning phase of a long-term bootstrap or colonization campaign.

If the survey is leading up to a bootstrap campaign, much may already be known about the target world. However, detailed maps of the world's features and studies of the world's weather and climate need to be made, as well as ground surveys of its agricultural and mineral resources. In this case, skip the star system details and go to page 9 of the Survey chapter.

If the survey is leading up to a colonization campaign, the survey may well be dealing with a world and star system that are

mostly unknown. A survey begins the moment the survey ship breaks out of jump space. The survey team uses their Astrogation skills to make sure they are in the right place, and how to find their way home. Then they search for the system's habitable planet and determine the system's features using the Stars & Planets chapter of this handbook. In this case, go to page 9 of the Survey chapter.

Once the target planet is located, the surveyors take their ship in for a closer look, mapping the planet and studying its weather. If it still seems to be a good place for a colony, ground survey teams are landed. These teams analyze the soil for fertility, probe for potential mineral deposits, check the atmosphere for all kinds of contaminants, and so on.

A survey mission intended as a stand-alone adventure provides plenty of potential action, too: contact with indigenous peoples or dangerous animals is always a possibility. This is a relatively short term operation, and with some preparation can be easily used for low-level day-to-day wilderness adventuring; see page 23 of the Survey chapter. If refereed with imagination, it can be a great adventure used to introduce the novice player to **Traveller** role playing and to the New Era.

Bootstrap

Bootstrap operations involve sending small teams to friendly worlds or friendly nations on balkanized worlds near the Reformation Coalition, and uplifting friendly indigenous peoples into partnership with the RC. These teams include diplomatic, agricultural, geological, civil engineering, medical, industrial technology, communications, and military specialists. They establish friendly relations with the local government, dispense medical care to the local population, help local farmers improve the yield and diversity of their crops, and help establish local industries that use indigenous resources to improve the area's technology. Because teams are often inserted in hostile territory, they include military specialists that help provide security for the team's civic action personnel. When a bootstrap team is working with a friendly government on a balkanized world, the military specialists also work as military advisors to their host governments. They help train indigenous troops to defend themselves and the civic action teams from attacks by hostile forces. The bootstrap concept is not new to the Coalition. It is an age-old idea that a nation can win over the "hearts and minds" of a less advantaged people by showing them the tangible benefits of allying with the more advantaged nation.

Bootstrap campaigns are likely to begin with low-level roleplaying as the team becomes established. It will probably shift to high level as on-going survey, education, and industrialization work begins. Here, the players will plan and monitor the results of their work in their specialties. Crises will erupt, however, demanding the return to low-level roleplaying—often at unexpected times.

Referees can tailor a bootstrap campaign to their own and their players' interests and abilities by assigning players to appropriate characters and roles. Players interested in a campaign emphasizing high-level roleplaying can be the team leaders, or agricultural or technological advisors. A bootstrap campaign involving more one-on-one low-level play can revolve around characters playing medics or explorers gathering resource and social data in the countryside around the team site. Action/adventure players can participate as military specialists providing security for the team or military advice to indigenous forces.

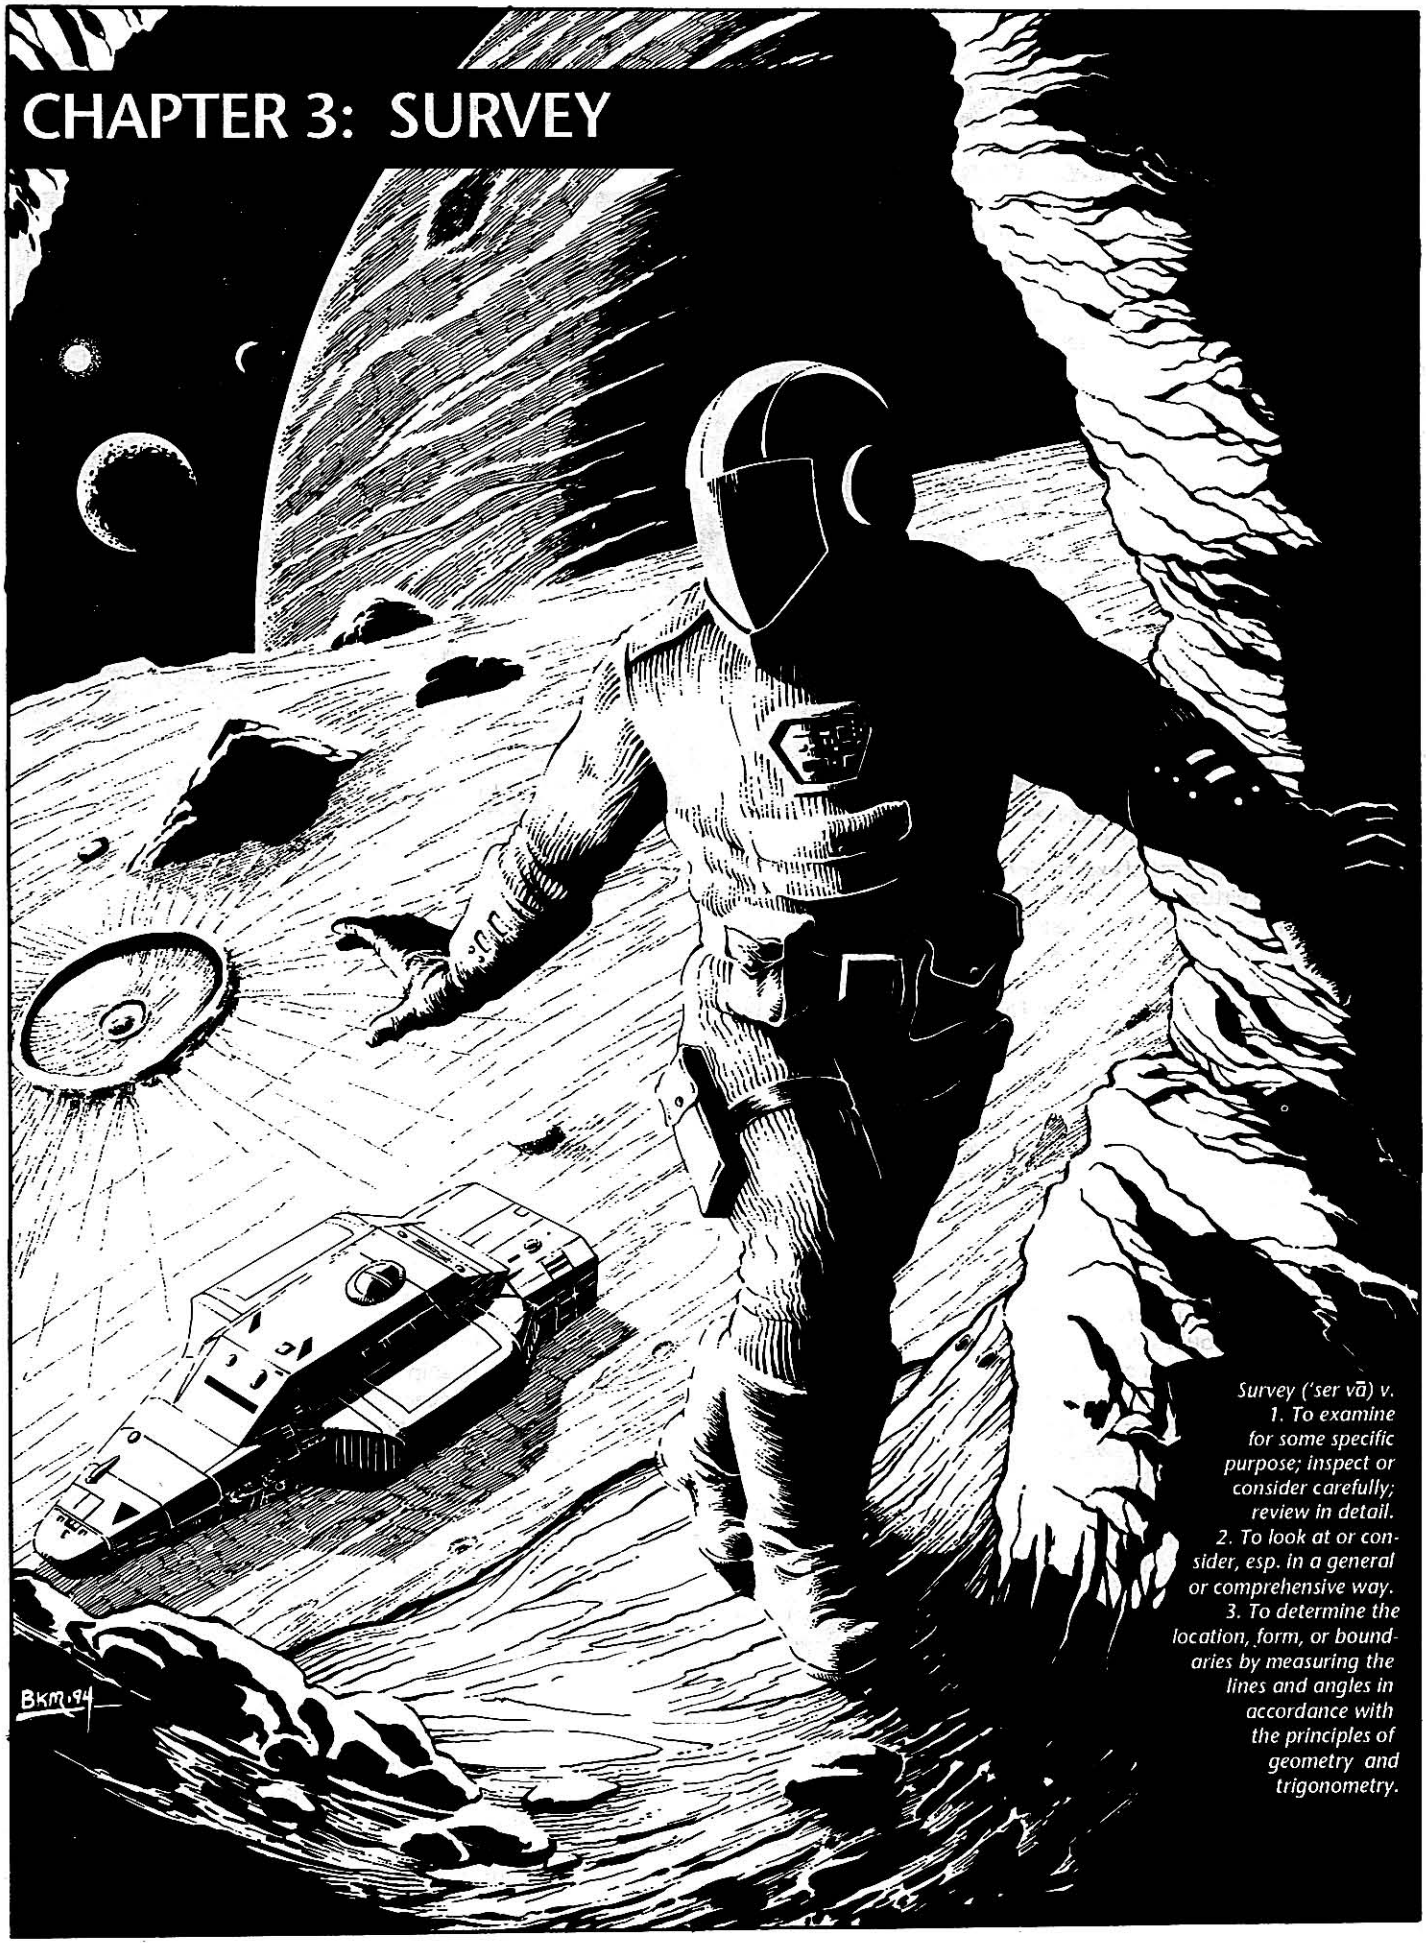
A bootstrap campaign is a long term campaign lasting a year or more in game time. Your players, especially action/adventure types, may not want to wait that long for their rewards. To get around this, limit their service with the team to a specific length of time and move them on to another campaign scenario, either on the same world or elsewhere. More patient characters who stay for the full campaign will earn greater rewards than a mere salary.

If the players are to be team leaders or specialists that expect to play the full campaign, go to page 48 of Chapter 6 Bootstrap. If no system survey data is available, go to page 9 of the Survey chapter. If the players expect to play a short-term campaign with a specific specialty and purpose, go to page 61 of the Bootstrap chapter. In order to run a bootstrap campaign, the referee must be familiar with the mechanics of Chapters 4, Colonial Economies and Infrastructure, and 5, the Mass Combat system.

Colony

In this campaign, your characters are hired by the Reformation Coalition world of Baldur to lead the colonization of a world just outside the RC. Baldur, a water world with a poisonous atmosphere, is one of the rare worlds to survive into the new era which cannot support human life without technological assistance. It is one of the most pragmatic supporters of the Coalition's charter to rebuild interstellar civilization and is willing to "go it alone" if necessary. Not only will Balduri-colonized worlds add to the growth of the Coalition, they will also enhance Baldur's economic weight within the Coalition by broadening its markets and expanding its variety of exports. Unlike the mother world, however, all of the Balduri colonies are to be created on habitable worlds for simplicity and to avoid dependence on external sources of technology.

If no current survey data is available, your players should begin by flying a survey mission to the target world and determine if it will support a colony. If not, they may want to continue exploring nearby worlds until a suitable planet is found. In these cases, start your adventure with page 69 of Chapter 7, Colony, for players' information and then go to page 9 of the Survey chapter. As the colony adventure focuses on economic leadership and administration, the referee must be fully conversant with Chapter 4, Colonial Economies and Infrastructure.



The next step of the colony campaign is to recruit colonists. If the players and referees intend to have the option for low-level play, this step will involve the players personally interviewing key professionals and technicians. Then a transport will take the players and colonists to their new world where they will establish a settlement on a lightly or totally uninhabited continent. Here they will make crucial decisions determining the allocation of limited resources to get the colony started out, and build it into a self-sustaining economy with off-world trade.

A colony campaign has both high and low-level role-playing, much like the bootstrap campaign. However, the circumstances and feel of the campaign are much different. Instead of dealing with a primitive native population and the dynamics of existing governments, your players are, for the most part, dealing with people from a settled world suddenly dumped on their own into the wild frontier. They must rely totally on what they carry with them to the new world. Careful planning is essential as they determine how many people to devote to agriculture and how many others to produce materials and develop industry in the colony. Although crises will occur and there will be opportunity for one-on-one adventure, a colony campaign is probably more suited to referees and players who like a more analytical game.

Other Worlds

The use of this book is not limited to the above campaigns; these are examples only. By mixing and matching portions of this book, and by creating new situations and environments, **World Tamers Handbook** provides a springboard for an infinite variety of adventures on frontier worlds. Leap backward into ancient history and begin on Earth, colonizing a world orbiting Alpha Centauri as the Terran Confederation begins to reach out into interstellar space. Or, in the New Era, begin in a Pocket Empire that is beginning to expand to its neighboring stars, or start the re-expansion of the Regency as it works to rebuild the glorious fallen Imperium. You are limited only by your imagination.

CHAPTER 3: SURVEY

Survey ('ser vā) v.
1. To examine for some specific purpose; inspect or consider carefully; review in detail.
2. To look at or consider, esp. in a general or comprehensive way.
3. To determine the location, form, or boundaries by measuring the lines and angles in accordance with the principles of geometry and trigonometry.

REFEREE'S INTRODUCTION

The survey chapter is provided as an adventure to let your players gather star system and planetary information either as a stand-alone mission or as a prelude to bootstrap or colony campaigns. It is to be used along with the Stars & Planets chapter, which contains TNE's detailed star system and planetary generation rules.

This chapter is not mandatory if your players are interested in the bootstrap or colony campaigns. The RCES may have already surveyed target worlds and their systems, and have compiled briefing sheets for some worlds. These are available in the Bootstrap and Colony chapters. On the other hand, your characters may know of an interesting world and have hired on as free lancers for RCES to map and survey that world in detail.

If you use the briefing sheets, you may want to reveal some or all of the information to your players at the beginning of the campaign. This would eliminate the need for a survey mission. However, if they want to fly a survey mission, you can then use the information in the sheets as the results of their survey work, revealing it in small bits as the players perform their survey tasks.

For an even greater sense of exploration if the player characters are heading into the virtually uncharted Wilds, use the rules in this and the Stars & Planets chapter to create a star system from scratch. You can create your own planetary maps using the mapping guidelines found at the end of Stars & Planets.

The Exploration section in the basic TNE rulebook should also be consulted for additional details and considerations.

STARTING OUT

Characters hiring on for a survey mission as a prelude to both the bootstrap and colony campaigns will be hired on at Baldur, also the starting point for both these campaigns. Stand-alone survey missions may begin at any major Reformation Coalition world including Oriflamme, Aubaine, Aurora, or Nike Nimbus. However, the traditional starting point of RCES missions spinward into the Wilds is Dawn Base on Trybec.

If the survey mission is part of a colony campaign set elsewhere than the RC, they should start the mission at the sponsoring world of the colonization campaign. This may be in a pocket empire, somewhere near Terra, or even in or near the Regency.

Survey Ships

No matter where they start, the characters will need a survey ship for their mission. In an RC campaign, they may be aboard a Coalition ship with other free-lancers or RCES members. Or, the RCES may loan them a ship. Elsewhere, the sponsoring world government will loan them a survey vessel.

To determine the exact type of ship the group receives, roll 2D6 on the Recon Ship Table. One of four types may available:

RECON SHIP TABLE

2D6	*Ship*
2	Survey Ship
3	Lab Ship
4	Scout
5	Scout
6	Far Trader
7	Scout
8	Far Trader
9	Scout
10	Far Trader
11	Far Trader
12	Lab Ship

(See TNE pages 366-379 or the **Brilliant Lances Technical Booklet** for technical descriptions of these ships.)

Survey Ship: A *Donosev*-class survey ship originally built for the Last Imperium as one of a fleet for the Imperial Second Survey. Although it has deteriorated since it was built nearly 100 years ago, the *Donosev* class has the best suite of survey and detection instruments available. This vessel also has an excellent laboratory aboard. She is capable of Maneuver 2 and Jump 3, and includes a 50-ton modular cutter and three air rafts as subordinate craft for close-in survey work and refueling operations. Drawbacks: a small PC group would be hard pressed to crew this large vessel. And it is probably the ugliest ship in the sky.

Lab Ship: Originally designed as a mobile base for scientific studies, the lab ship is the next best choice to the survey ship. She contains good quality survey instruments and a laboratory. She also has roomy accommodations and can carry a survey team of up to 20 members as well as five crew members. The lab ship is designed to be on station at a world under study for long periods. Consequently, she is ring-shaped and can be spun about her fore and aft axis to produce artificial gravity without using ship's power.

The lab ship has a 10-ton launch for use as a close-in survey and landing vehicle. The lab ship is capable of Maneuver 1 and Jump 2.

Scout Ship: A pre-Collapse scout ship, this vessel has barely adequate survey and detection gear. Accommodations are also cramped, especially for a long voyage. The ship has also been overhauled many times with non-standard components, and should be treated as having a wear value of 8 (see TNE pages 241-244). The scout is capable of Maneuver 2 and Jump 2. This ship has one advantage, it can land on planets with atmospheres.

Far Trader: This is a tramp cargo vessel capable of Maneuver 1 and Jump 2, when it works right. This decrepit starship may suffer a breakdown at any moment. The hull and engineering systems are held together with rust, spit, and bailing wire. The survey instruments and detection gear are whatever the characters can hang on her hull. She can land in atmosphere, though. A rudimentary lab can be installed in her cargo hold. The same engineering conditions found in the scout are found aboard the far trader.

Note that densitometers are available only on a Survey Ship or Lab Ship. Scouts and Far Traders only have passive EMS, active EMS, and optical survey equipment.

STAR SYSTEM EXPLORATION

If your players are entering an unknown system, they need to find out what stars are there. To generate star systems at random, see the "Stars" section on page 82 of the Stars & Planets chapter later in this book.

Then, develop the star system's planets using the procedure in the "Planets" section of that chapter. Note that the most likely colony sites will be found orbiting type F, G, and K stars. See the "Stars" section for a detailed discussion of stellar spectral types.

Where Are We?

Her body seemed to turn inside out then right side in again as the scout ship Skylark *stepped out of jump space. Everything seemed totally muddled for a minute, and then became really confused as Lane realized the stars were not in their expected locations.*

Lane leaped to the astrogator's panel as soon as jump shock started to wear off. After a couple of fumbling tries, she zeroed the computer-linked astrogation telescopes to three reference stars and ran the astrogation program. She swore softly, rechecking the numbers. "Captain, we're ten degrees above the ecliptic, and 20 degrees rimward of where we should be. Captain, our exit point was perfect, but the system's moved!"

"Then you better be damn careful about plotting breakout, Lane. You foul this up and we'll never get home. The charts of this system haven't been updated in nearly 100 years—you have to expect the system to move. Why do you think the Imperium ran surveys? To keep some bureaucrats busy?"

The Captain swiveled around to his computer console and pulled up the local ephemeris from Skylark's *database. He slaved the ship's main telescope to the computer, which pointed the 'scope toward where the system's life zone planet should be. "Now lets see... Let's see if Beta is where she should be.. and do we have a week, a day, a month, before we can get to her? Too bad the densitometer's down. We'll just have to do this the old fashioned way."*

Breaking out of jump space is nearly always disorienting; it's even more so in the New Era. Minds are muddled and there's a period of confusion while the starship crew tries to plot its location. These days, there are no friendly beacons broadcasting the system's coordinates and the maneuver vectors to the main world, and 80 years of stellar motion has resulted in star systems that have shifted relative to each other, meaning that arrival in a star system will not always be where the crews expect.

With luck and a Survey or Lab Ship, your crew will have a working densitometer to find the system's worlds. Usually, however, they'll only have a telescope (included in all starship avionics suites); a device needed for two critical tasks.

First, the adventurers have to confirm they've arrived at their intended destination, and compute the difference from their expected destination. They do this by determining the angles of three or more reference stars relative to the galactic center (Difficult: Astrogation).

Second, they must refine this data relative to the system's main star to determine exactly where they have broken out of jump space (Difficult: Astrogation) in order to find their way to worlds or refueling points in the system.

These calculations are necessary when jumping back out of the system to correct for the system's motion to allow arrival at the desired point in the destination system. Failure to properly calculate these changes can cause a ship to be lost, as it may find itself out of position relative to a refueling source or destination world, and have insufficient fuel to make the course corrections to make it there. Such a ship will simply pass right through the destination system and coast off into the interstellar void.

Systems that have been visited and surveyed in the New Era do not present this problem, but whenever a ship attempts jump to a system which has not been visited since the Collapse there will be difficulties with computing the correct jump to arrive in that system in its new location relative to the departure point.

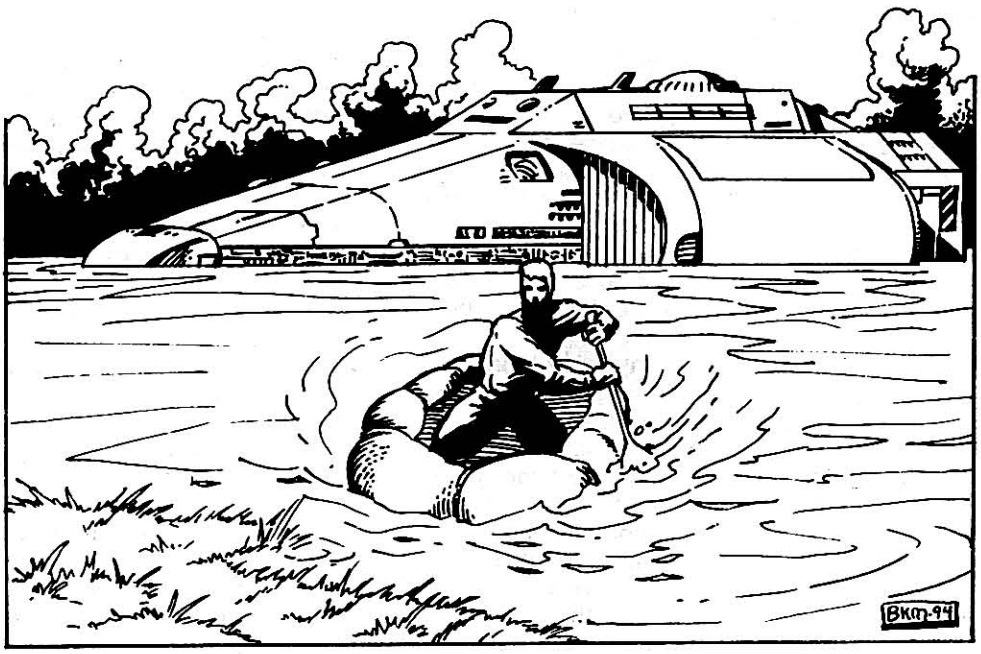
What's Here?

The players' next job is to determine the number of planets in the system, their type and location, and which—if any—may be habitable. To do this, follow the procedure in the "Planets" section. Because the characters won't want to waste resources surveying a world outside the life zone, just note these planets for future reference. Planets in the habitable zone can then be analyzed for their suitability as colony sites. Planets with no water, extreme atmosphere types or atmospheric taints may be eliminated early, but other worlds will require more detailed analysis to determine the complex interplay of their characteristics.

Is Anybody Home?

With passive sensors operating, the PCs take their ship into far orbit around the target planet. Meanwhile, if the planet is not a published or pre-generated world, the referee must secretly roll the characteristics of the target planet including population and technology levels. When in far orbit, the characters check for radio wave emissions and distinctive unnatural patterns of infrared radiation, as well as visible light from the night side of the target world (Difficult: Sensors, uncertain). Radio and infrared, and extensive visible light, indicates that an established pre-industrial or higher civilization already occupies the world. Unless all of the above come from a limited region, such as a single continent, these would rule out the target world as a colony home. However, it might be ideal for a bootstrap operation, and indicate possible points of contact.

With the ship's active and passive EMS arrays, the players should determine the planet's size (Average: Survey), the atmospheric composition and whether water vapor is present (Difficult: Sensors, uncertain), and the world's axial tilt (Average: Sensors, see page 85). If they have a working densitometer, they can determine the planet's density and its expected gravity based on its size. (Use the World Density and World Gravity tables on page 87.) They can use the ship's visual systems (part of the ship's astrogation and avionics package or its passive EMS array) to determine the presence of any large bodies of free water on the planet (Average: Survey). As they perform these tasks, the referee should give them approximate answers based on the secret rolls or the pre-generated world data.



If the planet appears unoccupied, and the world has water and a breathable atmosphere, the world would be a strong candidate for a colony. If there appears to be a low-tech civilization, without one or more nodes of relatively higher technology which would indicated the presence of a TED, the world might be a good candidate for a bootstrap operation. In either case, the players should move their ship into close orbit and begin orbital scanning and mapping.

What's On the Ground?

This is where the real survey work begins. The ship's cameras and imaging EMS array begin examining the world from close orbit and producing maps of the world's oceans and continents including major terrain features such as mountain ranges, rivers, bays, forests, grasslands, and deserts. This examination can also spot any signs of previous or current habitation (Difficult: Survey, or Formidable if local technology level is 1 or lower). Imaging EMS can produce maps of surface features scanned through cloud cover.

This information can be gradually revealed to the players either from the maps provided with RCES briefing sheets.

This should take a number of hours equal to 1D6 times world's UWP size digit; e.g., a size 7 world takes 7D6 days to map. At the same time, infrared visual and radio frequency scanners are passively looking for signs of technology below that may have been missed from far orbit (Difficult: Survey and Sensors, Formidable if local technology level is 1 or lower). The referee should reveal full information about the planet's size and hydrographic percentage, and the population and technology level if the detecting signs of habitation task succeeds. Once the relative percentages of land and ocean area are known, The referee and players should begin developing a map of the planet .

The players should also note the planet's cloud cover and weather, and while in orbit , determine if any violent weather systems are at or near proposed landing sites. If the ship has a working densitometer, this instrument can be used to detect large mineral deposits (Difficult: Sensors). However, core samples will need to be taken to determine the type of mineral in each deposit. See the basic TNE Exploration rules (pages 205-206) for additional details.

FIRST LANDING

The planet rolled beneath the lab ship, blue, green, and lovely; a world virtually unscarred except for the glassy crater where the naval base had been located nearly a century ago and the ruins of a city nearby. A large island just offshore of the northern continent's east coast looked like a strong candidate for a landing site. It was on the opposite side of the continent from the ruins. If there were any indigenous survivors that had been blasted back to the stone age, the continent's central mountain range should keep them away from the colony site. A semi-circular bay opposite the mainland promised calm waters and the river delta feeding into the bay would supply both fresh water and fertile soil.

Lane fired the boat's thrusters and the small vessel dropped away from the mother ship. She always trusted the small craft's wings much more than the rather decrepit grav units, so Lane decided to make an aerodynamic approach and a water landing in the bay. High altitude turbulence rocked the boat hard as Lane circled the island to kill off entry velocity, but calmed as she turned on final approach to the bay. Clouds of steam exploded off the hot hull as she splashed down onto the bay waters and taxied toward the shoreline. The boat lurched gently as she touched the beach. Meanwhile in the rear compartment Harley was working the atmosphere tester. "It looks clean, Lane. We got a green light. No bios, no pollutants, no nothing; just fresh clean air."

"OK Harley, I hope you're right."

Seals popped and air hissed as pressure equalized in the airlock. Clad in her vac suit, Lane stepped onto the beach and moved inland toward rolling dunes covered with gray-green grass. Blue mountains and their upland valleys shimmered in the heat haze beyond. A river in spring flood flowed into the bay on her left.

The atmosphere tester's telltale light still glowed green. Lane opened her helmet seal and breathed free air for the first time in six weeks. The air smelled sweet, of sea salt, warm earth, and waving grasses. No ozone, no plastic fumes, no nitrogen toxins; just sweet, clean air.

"Harley," she called into her communicator. "Radio the captain. Tell him this is the place."

The characters will spend a fair amount of time exploring several sites as potential locations for their colony. These sites should have the potential for fertile farm and grazing land, and/or be close to potential mines for metals or fuels. If the terrain is mountainous or heavily forested, and no flat open landing areas are available, the characters should be able to set their landing craft or starship down on a lake or bay (Average: Pilot [Interface/Grav]).

In the following passages, there are guidelines for two broad types of Survey tasks: *General* and *Goal-Oriented Survey tasks*. These two categories are separated into two sections, below.

General survey tasks are those which establish the specific nature and details of the world according to standard categories and classifications. The results of these tasks constitute the bulk of data which will make up the standard planetary survey report.

Goal-oriented survey tasks are more specific in nature, in that they go beyond the standard report of what the planet is like, and seek to identify particular sites on the world which are suited to various types of exploitation. The prime example of such sites would be projected colony locations, possessing good arable land but situated near potential sources of minerals, etc.

GENERAL SURVEY TASKS

General survey tasks begin with determination of the qualities of the world's atmosphere: its pressure and its composition. For the purpose of finding suitable colony worlds, atmospheres with exotic compositions (codes A-C) and atmospheres too thin to breathe (0-3) are not really dealt with here. Rather, worlds of a basically earth-like composition at pressures varying from thin to dense will be looked at. In addition to their pressure-related

Uncertain Tasks

The principles of uncertain tasks are explained on TNE page 111, and are very important when conducting planetary surveys. Referees should treat most any task in a survey mission as an uncertain task, because the PCs will be attempting to determine the absolute truth about the nature of a world, and such information is not always available as the result of a single test.

This fact will encourage the PCs to conduct certain survey tasks more than once, to decrease the likelihood of undetected error. Each such repeated task should have its difficulty reduced by one level to reflect the greater certainty obtained by multiple investigations. Players may also think to conduct the same survey tasks at a variety of widely-separated locations, rather than just in one location where they could be fooled by unique local conditions, and referees may decide to reward such forethought by further bonuses.

It is always possible that the hidden result of a failed uncertain survey task could be the difference between life and death for a shipload of colonists. Referees must be careful to secretly record all true data that is unknown to the survey team, so that its consequences can be implemented at the proper time. This is the best way to ensure that a PC survey team takes its responsibilities seriously.

qualities, these atmospheres might also have significant additional components which will affect their suitability for habitation.

Atmospheric Pressure

Within the range of breathable atmospheric codes (code 4-9 on the Universal World Profile), **Traveller** treats worlds as having a basically earth-like oxygen-nitrogen mix (approximately 20% and 80%, respectively). This means that these atmospheres are basically breathable by humans. However, there is variation from earth norms in certain details, such as atmospheric pressure (other variations are dealt with below).

There are three basic levels of atmospheric density where humans can breath without assistance: Thin (codes 4 and 5), Standard (codes 6 and 7), and Dense (codes 8 and 9). Each density level has its own particular details. (For this discussion of density, the tainted and untainted versions of each density level are treated as being the same.)

The material below includes fairly detailed guidelines for handling the physiological effects of differing atmospheric pressures. These guidelines are presented for referees to use *where appropriate*, and are not required rules that must be slavishly adhered to at all times.

For example, if the PCs' ship lands on a world and the crew merely engages in routine trading and then departs, there is little need for the referee or players to worry about the effects of differing atmospheric pressures. If, however, the crew gets involved in a lengthy, strenuous barroom brawl, the effects of a thin atmosphere may be significant. And if the PCs are a mercenary unit intending to become involved in a lengthy military campaign, the rules below on acclimatization and physiological effects will loom very large indeed.

Thin: Thin atmospheres range in pressure from 0.43 to 0.70 standard atmospheres (where a standard atmosphere has a pressure of approximately 1 kilogram per cm^2). For simplicity, **Traveller** treats all atmospheres within this range as functionally equivalent. See the "Physiological Effects" section below for potential physiological effects of standard atmospheres on characters not accustomed to them.

Aerodynamic aircraft (fixed- and rotary-wing) also have their performance affected in thin atmospheres, see the "Aerodynamic Aircraft in Thin and Dense Atmospheres" sidebar on page 15.

Detailed Atmospheric Pressure: If referees or players desire greater detail in the atmospheric description, the referee may roll 1D10 (or, for more detail, D100) and express the result as a decimal (i.e., 4 becomes 0.4). Multiply this decimal by 0.27 and add the result to 0.43. The result is the atmospheric pressure in standard atmospheres. However, these rules will not stipulate any additional effects for a thin atmosphere of 0.43 atmospheres as compared to a thin atmosphere of 0.7 atmospheres. In **Traveller**, all thin atmospheres are treated as broadly equivalent, rather than requiring harried referees to treat each planetary atmosphere as unique. Experienced referees and players are free to do so, but in deference to the majority of players and referees who do not wish this burden, the **Traveller** rules will not address this issue in detail.

Standard: Standard atmospheres range in pressure from 0.71 to 1.49 atmospheres. As with thin atmospheres above, **Traveller** treats all atmospheres in this range as functionally equivalent. See the "Physiological Effects" section below for potential physiological effects of standard atmospheres on characters not accustomed to them.

Detailed Atmospheric Pressure: If referees or players desire greater detail in the atmospheric description, the referee may roll 1D10 (or, for more detail, D100) and express the result as a decimal (i.e., 4 becomes 0.4). Multiply this decimal by 0.78 and add the result to 0.71. The result is the atmospheric pressure in standard atmospheres. However, these rules will not stipulate any additional effects for the difference between an atmosphere of 0.71 atmospheres and an atmosphere of 1.49 atmospheres. See this section under Thin atmospheres above for further discussion.

Dense: Dense atmospheres range in pressure from 1.50 to 2.49 atmospheres. As with thin atmospheres above, **Traveller** treats all atmospheres in this range as functionally equivalent. See the "Physiological Effects" section below for potential physiological effects of dense atmospheres on characters.

Aerodynamic aircraft (fixed- and rotary-wing) also have their performance affected in dense atmospheres, see the "Aerodynamic Aircraft in Thin and Dense Atmospheres" sidebar on page 15.

Detailed Atmospheric Pressure: If referees or players desire greater detail in the atmospheric description, the referee may roll 1D10 (or, for more detail, D100) and express the result as a decimal (i.e., 4 becomes 0.4). Multiply this decimal by 0.99 and add the result to 1.50. The result is the atmospheric pressure in standard atmospheres. However, these rules will not stipulate any additional effects for the difference between an atmosphere of 1.50 atmospheres and an atmosphere of 2.49 atmospheres. See this section under Thin atmospheres above for further discussion.

Physiological Effects: There are two types of atmospheric pressure adjustments: "going up" from a lower pressure (thinner) atmosphere to a higher pressure (denser) atmosphere, or "going down" from a higher pressure to a lower pressure atmosphere. Thinner atmospheres do not typically provide as much oxygen as denser atmospheres, and denser atmospheres typically provide too much oxygen as well as other, inert, gases. Either of these conditions may adversely affect characters adapted to other atmospheres until they become acclimatized to the new atmosphere (see the "Atmospheric Adaptation and Acclimatization" section below for details).

Referee's Note: Remember that the purpose behind these rules is not to bog down play whenever the PCs journey from one atmospheric

Physiological Difficulties from Atmospheric Pressures

Because **World Tamers Handbook** is about building societies on habitable worlds, it does not deal with the obvious difficulties of attempting to breathe ammonia, for example. The atmospheric variations dealt with in **WTH** are mostly limited to atmospheres of a basically Terran composition (approximately 20% oxygen, 80% nitrogen, plus other trace gases) but which exist at different pressures. As it turns out, simple differences in pressures are sufficient to provide significant physiological difficulties.

Insufficient Oxygen: This is perhaps the most obvious effect. A partial pressure of oxygen of less than 0.1 atmosphere will not sustain life. Any combination of low atmospheric pressure and low concentration of oxygen can create this condition which is obviously quite fatal. Compressor masks (which collect oxygen from low-pressure atmospheres and compress it to breathable concentrations) are a simple and reliable antidote to this problem, fortunately.

A less severe variation of this is that on worlds with a lower than accustomed partial pressure of oxygen, persons will have a hard time with strenuous activities and will tire out more quickly, as their bodies have difficulty getting enough oxygen to sustain their activities. Fortunately most people can adapt to these situations over time, particularly with the benefit of medical attention. See the Acclimatization section.

Oxygen Poisoning: One more bit of proof of the wisdom of observing moderation in all things: too much oxygen will kill you as surely as too little. There are two main types of oxygen poisoning: chronic and acute.

Chronic oxygen poisoning is the more common of the two, and is seen at partial pressures of oxygen (PO_2) of 0.6-2 atmospheres, or 3-10 atmospheres total pressure assuming 20% oxygen as in the Terran-type atmospheres. Because this pressure is above the 2.5 atmosphere upper limit for dense atmospheres, this is typically not a problem, but higher than usual oxygen concentrations in a dense atmosphere can create the circumstances for this problem. Chronic oxygen poisoning causes inflammation, congestion, and hemorrhaging of lung and pulmonary tissues, and is manifested by shortness of breath, dry cough, and fatigue. Fortunately most humans can adapt to these conditions, and the symptoms will eventually reverse themselves (see the Acclimatization section).

Acute oxygen poisoning is fortunately only encountered when PO_2 is above 1.8 atmospheres (9 atmospheres assuming a 20% oxygen mix), and would therefore require a dense atmosphere which was almost pure oxygen, an unlikely circumstance to be sure. Acute oxygen poisoning affects the nervous system, and is manifested by such symptoms as nausea, muscular twitching, dizziness, choking, and convulsions followed by a loss of conciousness.

Inert Gas Narcosis (IGN): On Terran-type worlds this is typically known as nitrogen narcosis, as nitrogen is the most prevalent atmospheric inert gas. However, the gas need not be nitrogen, as any inert substance will create a depressant effect on the nervous system if enough of the substance goes into solution in the body's fatty tissues. IGN can be thought of as having an intoxicating effect and includes such symptoms as lightheadedness, loss of fine discrimination, euphoria, poor judgement, and slowed reflexes.

To provide an example, IGN caused by nitrogen at a partial pressure of 2.4 atmospheres has been shown to reduce reaction time by 20%, mechanical dexterity by 8%, and abstract reasoning by 33%.

Fortunately this phenomenon is associated with rather high atmospheric pressures: 3 atmospheres and above in the case of nitrogen, the predominant inert gas in Terran-type atmospheres. This means that the nitrogen form of IGN is not a problem in even dense atmospheres.

However, it is significant to note that nitrogen is hardly the most dangerous inert gas for this purpose in humans. The table at right shows the relative potency of several inert atmospheric gases, with nitrogen set as the standard.

Inert Gas	*IGN Potency*
Nitrous Oxide	25.9
Krypton	7.2
Argon	2.2
Nitrogen	1
Hydrogen	0.7
Helium	0.2

Thus, on a world where Argon or Krypton, rather than Nitrogen, was the dominant inert atmospheric gas (admittedly a rather unlikely circumstance), problems could develop at lower pressures. This potential is presented as food for thought for cruel and devious referees, and not as a common phenomenon.

Decompression Sickness: This is not a difficulty associated with a particular atmosphere type *per se*, but rather has to do with the act of transitioning from a more dense atmosphere type to a less dense atmosphere type. When living tissue exists within gas of a given pressure, some of that gas is absorbed into the tissue and held in solution. The amount of gas dissolved in the tissue is proportional to the pressure of the gas, so roughly twice as much gas would be absorbed in an atmosphere of twice the given pressure. The rate of absorption is limited by chemical functions such as solubility of the gas, and by biological functions, such as the rate of gas exchange in the lungs, the rate at which the blood moves the dissolved gases, rate of gas exchange between blood and tissue, etc. When remaining within an atmosphere of given pressure, the body attains gas equilibrium and will retain that equilibrium so long as it remains within the same atmospheric pressure.

If, however, the body is rapidly moved to an area of lower pressure, the tissue begins "degassing" to attain gas equilibrium at the new lower pressure. However, there are limitations as discussed above to the speed at which this can be done, and if the change in atmospheric pressure takes place more rapidly than the body can degas itself, the dissolved gas will come out of solution within the tissues and blood stream and form bubbles. The formation of these bubbles within various organs can cause serious physiological damage, and is known as decompression sickness.

Most symptoms of decompression sickness show up within an hour (and almost all of them within six), and these include neurological decompression sickness ("the staggers:" paralysis, dizziness, loss of muscular control, unconciousness, blurry vision, covulsion, numbness, weakness), joint involvement ("the bends:" pain and swelling in the joints), respiratory decompression sickness ("the chokes:" choking and burning sensation in the chest, shallow breathing, coughing, loss of conciousness, shock) and skin bends (rash and itching, not a real problem by itself).

One symptom which is not seen within the first few hours is one of the most crippling over the long term: aseptic bone necrosis, which can cause the destruction of joints, particularly those of the shoulders, hips, and knees. These symptoms can take from several months to as much as five years to manifest themselves, and can result from only very small changes in pressure which were accompanied by no other symptoms.

In the **Traveller** universe, decompression is usually handled aboard starships when travelling from one star system to another, as the one week+ travel time is sufficient for these purposes (note that decompression is not the same as acclimatization—a character who has been safely decompressed to a new atmospheric pressure is *not* acclimated to that atmosphere). If the entire crew is moving from one atmosphere to the next, the ship's life support system can be set to use the entire ship's inhabited spaces as a decompression chamber for the entire crew, gradually reducing the ship's internal atmospheric pressure at a safe rate until the crew is decompressed to the pressure of the atmosphere at the ship's planned destination.

If only a few passengers require decompression, this is usually accomplished by having them suit up with vac suits before boarding the ship (thus retaining the original high pressure around their bodies), and then moving them to their staterooms. Ship's life support can control environment one stateroom at a time, allowing these passengers to remain sealed in their staterooms until they are safely decompressed.

Note that decompression is required for such acts as meteoric assaults onto a world with a thin atmosphere. All troops preparing for a meteoric assault undergo decompression to the target world's atmospheric pressure before entering their drop capsules, and are carefully screened for respiratory ailments which increase the risk of decompression sickness by interfering with the body's degassing processes.

Other conditions contribute to the chance of decompression sickness and are carefully controlled before a jump, which helps explain many of the pre-drop rituals of drop troops: no alcohol for 12 hours before a jump, no tobacco or similar substances for an hour, high-protein, low-fat meals, properly fitted suits, increased fluid intake, no exercise during decompression, and keeping the body warm.

And Now the Good News: In the future universe portrayed in **Traveller: The New Era**, mankind (and other starfaring races) have been dealing with the above phenomena for centuries, and they are not the problems they might otherwise be. Standard procedures for safe decompression and acclimatization have been used for so long that the average traveller scarcely even notices them, and simple, effective drugs to ease these adjustments are readily available and are administered expertly by the innumerable versions of flight surgeous, drop medics, ship's doctors, astrophysiologists, and the like.

The above details are presented primarily as part of the ongoing effort to keep the science in science fiction, and to provide details for referees who would like to be able to provide a little bit of color to remind their players that even in the future, things sometimes still go wrong.

type to another, but rather to demonstrate the complications faced by an interstellar society which encompasses a literally infinite variety of planetary environments. These effects are not necessarily felt by travellers casually visiting or trading among such worlds, but, for example, an invasion of a world by troops not adapted to its conditions would be very much affected by these physiological realities.

Since the symptoms of physiological difficulties of going up to higher oxygen concentrations and going down to lower oxygen concentrations are so similar (characterized by fatigue, shortness of breath, etc.), for simplicity the same procedure is used for both upward and downward adjustments. However, referees may feel free to customize the physiological effects somewhat to more precisely describe a certain ailment, using the Physiological Difficulties sidebar as a guideline.

Procedure: When attempting strenuous physical activities (referee's discretion, but this should include such activities as running, carrying heavy loads, cross-country hiking in hot weather), characters adapted to a different density of atmosphere than the one they currently inhabit will have to make a roll against their Constitution attributes to avoid adverse physiological affects due to the different atmospheres. (See section below, "Atmospheric Adaptation and Acclimatization," for discussion of atmospheric adaptation.)

The frequency of these rolls is also at the referee's discretion based on the nature of the activity and the level of detail being played. During combat these rolls might be made every five minutes, but if a character runs with a heavy pack for several turns in a row, the roll might be made immediately in response to these actions. During long-duration cross-country travel, the rolls might be made each hour or half hour.

The basic difficulty level of these rolls is Difficult, with the following difficulty modifiers. Diff Mods are cumulative, but the final difficulty level can be no greater than Impossible. If the referee is handling NPC groups, such rolls should only be made once per NPC *group* (not once per NPC) based on the experience level of the NPCs.

Success: Success indicates the character experiences no difficulty, and may go about his or her business without interruption until next required to make the roll. At the referee's discretion, Outstanding Success may allow the character to skip the next required physiological effects roll.

Failure: Failure indicates the need to immediately sit down and rest. While resting, a character's Initiative and Strength attribute are each reduced by 1, and the character may not conduct Aim, Crawl, Stand Up, Melee, Run, Trot, or Walk combat actions. At the end of every minute (12 combat turns) spent resting, the character makes a Difficult roll against Constitution. Success indicates that the character has rested sufficiently and returns to normal. Failure and Catastrophic Failure both indicate that the character must continue resting and roll again after another minute.

Catastrophic Failure: Catastrophic Failure indicates that the character has lost conciousness. Characters who lose conciousness in this way are treated the same as those who lose conciousness due to a serious wound (TNE page 288). Such characters make a Formidable roll against their Constitution every 30 seconds to attempt to regain conciousness. Once conciousness is regained, they are treated as resting (above).

Referees may grant longer periods between rolls or –Diff Mods for mitigating circumstances such as cool weather or air conditioning, use of powered armor (to reduce physical exertion), etc.

Atmospheric Adaptation and Acclimatization: The Physiological effects described above only apply to characters before they become *acclimatized* to the new atmosphere. Once a character is acclimatized according to the rules below, no more rolls for physiological effects are required, as the character has become completely physically accustomed to the new surroundings.

Characters who are not used to a given atmospheric density may have a hard time adjusting to the new conditions. For example, a character who has spent her entire life in a standard atmosphere will find it hard to function in a thin atmosphere, at least until she becomes acclimatized.

Atmospheric Adaptation: First, the referee must determine if a character is adapted to a certain atmospheric density. This is not as simple as determining the atmospheric density of the character's homeworld, as the character may have spent the last 10 years become used to an atmosphere with a different density and should be treated as adapted to this new atmosphere. Characters who have spent their lives living aboard a starship can become adapted to whatever conditions the ship's life support is set to. (For this reason, most Free Traders in the New Era have their shipboard environments set to 0.7 atmospheres, the borderline between thin and standard atmospheres, allowing their crews to be equally comfortable in either environment—this also provides a savings in life support usage and speeds the transition to battle stations.)

Once a character's adapted atmosphere is determined this is compared to the local atmosphere to see if acclimatization is required. All atmospheres of the same code are considered to be equivalent for purposes of the physiological effects and acclimatization rules. Thus a character from a world with atmosphere code 5 (thin) could travel to any other world with an atmosphere code of 5 without having to worry about rolling for physiological effects or acclimatization.

Acclimatization: From the moment a character arrives in a new atmosphere, his or her body will begin making the innumerable major and minor adjustments (most of which involve discomfort) to function efficiently in these new surroundings. This period can last for a long time or for a relatively short time, and is governed by a series of rolls against the character's Constitution attribute. One such roll is made at

DM's for Physiological Effects of Acclimatization

Diff Mod	*Circumstance*
+1 Diff Mod	if character is adapted to an atmosphere **two steps** away from the atmosphere currently occupied. For these purposes there are three steps of atmospheric density: thin, standard, and dense. From thin to dense or dense to thin is two steps, from thin or dense to standard or from standard to thin or dense is only one step.
+1 Diff Mod	if character is **burdened** or greater (see "Load," TNE page 35)
+1 Diff Mod	if character is **fatigued** (see "Fatigue," TNE page 198)
–1 Diff Mod	if character is **going up** from a thinner to a denser atmosphere
–1 Diff Mod	if character is **mostly acclimatized** (Stage 4, see Acclimatization section, below)
–1 Diff Mod	if character with **Medical skill** is in attendance. This is only possible when the characters are operating as a group, in surroundings where the medic is free to circulate among the characters to periodically examine them for signs of exhaustion, etc. This would not be possible, for example, if the characters were in combat, spread among a number of separate foxholes. Not more than 20 characters may receive this benefit from a medic (thus a group of 100 NPC troops should have five medics in order to receive this benefit).

the end of each week until four successful rolls have been made. Success at each roll allows the character to pass on to another stage, in which the penalties for not being adapted to the atmosphere become steadily less.

Stage 1: Stage 1 is the period from arrival in the new environment until success is acheived on the roll to pass into Stage 2. This roll has a base difficulty of Impossible vs. CON (see below for die modifiers and Diff Mods). While in Stage 1, rolls for physiological effects (as described in the section above) are required. Also, when using the fatigue rules (TNE pages 198-199), work which would normally be defined as easy work is treated as hard work, and work which would normally be treated as hard work yields two levels of fatigue instead of only one. When using the economic model (Chapter 4), an economic sector whose laborers are in this stage suffer a –4 DM on the monthly output roll. Military units whose personnel are at this stage have a constant 4 fatigue levels for purposes of the Mass Combat Rules, see page 46 for more details.

Stage 2: Stage 2 is the period after the first roll vs. CON is successfully made, but before the second roll is made to pass into Stage 3. The base roll to pass out of Stage 2 is Formidable vs. CON (see below for die modifiers and Diff Mods). While in Stage 2, rolls for physiological effects are required. Also, when using the fatigue rules, each period of hard work yields two fatigue levels instead of only one. When using the economic model (Chapter 4), an economic sector whose laborers are in this stage suffer a –3 DM on the monthly output roll. Military units whose personnel are at this stage have a constant 3 fatigue levels for purposes of the Mass Combat Rules, see page 46 for more details.

Stage 3: Stage 3 is the period after the second roll vs. CON is successfully made, but before the third roll is made to pass into Stage 4. The base roll to pass out of Stage 3 is Difficult vs. CON. While in Stage 3, physiology rolls must be made, but there are no modifications to the normal fatigue rules. When using the economic model (Chapter 4), an economic sector whose laborers are in this stage suffer a –2 DM on the monthly output roll. Military units whose personnel are at this stage have a constant 2 fatigue levels for purposes of the Mass Combat Rules, see page 46 for more details.

Stage 4: Stage 4 is the period after the third successful roll vs. CON is made, but before the final roll is made to become fully acclimated. Physiology rolls are still required, but these are made at –1 Diff Mod. When using the economic model (Chapter 4), an economic sector whose laborers are in this stage suffer a –1 DM on the monthly output roll. Military units whose personnel are at this stage have a constant 1 fatigue level for purposes of the Mass Combat Rules, see page 46 for more details. The roll to pass out of Stage 4 and to become fully acclimated has a base level of Average vs. CON.

Stage 5: Characters which have succeeded at the roll to pass out of Stage 4 are fully acclimatized to their new environment and need not concern themselves with further physiological rolls or other deleterious effects.

These details are summarized on the table to the right.

Only one acclimatization roll may be made per week. Modifiers to this roll are as follows:

There is a –1 Die modifier (not Diff Mod) for each additional attempt on the roll to get out of the current stage, i.e., total the number of weeks in the current stage, subtract 1, and the result is the –DM to be used on the roll. A –Diff Mod is also applied if medical assistance is available.

Characters with Medical (Diagnosis) assets may assist in the acclimatization process by prescribing medication and supervising the acclimatization conditioning. In order to do so, the medic(s) must succeed at a Medical task. The base difficulty level of the task is Difficult: Medical (Diagnosis) assuming that the medic is supervising the acclimatization of 20 characters. (This also assumes that the medic has access to a supply of basic medical supplies—this varies with circumstances and referee's discretion.) The difficulty level of this task is increased one level for each doubling of the number of characters being supervised, or reduced one level for each halving. Thus 5 or fewer characters is Easy, 6-10 is Average, 11-20 is Difficult, 21-40 is Formidable, and 41-80 is Impossible.

Success indicates that the difficulty of the patient's acclimatization roll for that week is reduced by one level. Catastrophic Failure indicates that the acclimatization roll for that week is not allowed. (The referee may require a PC medic to make this roll for each character the PC is attempting to assist, or, usually in the case of NPCs, may allow a single roll to be made which affects all acclima-

Stage	*These Penalties Apply*	*Until This is Rolled*
1	Easy Work counts as Hard Work, Fatigue doubled for Hard Work, Physiology rolls required, –4 DM on Output Roll 4 fatigue levels for Mass Combat Rules	Impossible vs. CON
2	Fatigue is doubled for Hard Work, Physiology rolls required –3 DM on Output Roll 3 Fatigue levels for Mass Combat Rules	Formidable vs. CON
3	Physiology rolls required –2 DM on Output Roll 2 Fatigue levels for Mass Combat Rules	Difficult vs. CON
4	Physiology rolls required, but at –1 Diff Mod –1 DM on Output Roll 1 Fatigue level for Mass Combat Rules	Average vs. CON
5	Fully acclimatized, no further effects	N/A

tization rolls supervised by that medic for that week.)

Acclimatization Rolls: Success on the weekly acclimatization roll means that the character(s) passes into the next stage of acclimatization. At the referee's descretion, Outstanding Success may allow a –1 Diff Mod on the following week's acclimatization roll as well.

Failure simply means that the character remains at the current acclimatization stage and must attempt the roll again the following week.

If a Catastrophic Failure is ever rolled on an acclimatization roll, the character falls ill for 1D6 days. During this illness, all physiology rolls are made at one difficulty level higher, and all Easy Work counts as Hard Work.

Final Caveat: Do not slavishly adhere to these rules if they are not appropriate to the story and the action. They are only intended to add detail in circumstances where they would be appropriate.

Atmospheric Taint

Now the survey examines the composition of the atmosphere. As we have already discussed, the atmospheric envelope is assumed to consist primarily of nitrogen and oxygen in a 4:1 ratio. However, even trace amounts of particular additional materials can dramatically affect the overall breathability of the atmosphere, and will result in the atmosphere being classified as "tainted."

The following table shows the UWP codes used for the tainted and untainted versions of each of the three major atmospheric densities.

	Untainted	*Tainted*
Thin	5	4
Standard	6	7
Dense	8	9

Determining Taint: Although the surveying characters can have already established the chemical composition of the atmosphere by spectroscopic analysis from orbit, some contaminants, particularly biological ones, must be discovered by physical analysis of the atmosphere. This can be done by using a remote probe (the probe presented on page 118 of the **Reformation Coalition Equipment Guide** may be used for this purpose by placing an atmosphere sampling trap in the space reserved for the neural activity sensor; the probe then returns the sample to the mother ship for analysis there), or by personally sampling the atmosphere from the ground. This task requires the use of atmospheric analysis equipment present on any starship (for example, see the atmosphere tester on **TNE** page 346) and is an Average test of Chemistry or Biology. If the ship is equipped with a lab, the difficulty is reduced one level to Easy.

If the atmospheric study task is successful, the referee reveals whether the atmosphere is tainted or not. If it is contaminated, the testing character rolls on the Atmospheric Contaminants Table to determine what contaminant is present. If a contaminant requires the use of a filter mask and a domed environment, the world will be

Aerodynamic Aircraft In Thin and Dense Atmospheres: Aerodynamic aircraft (as opposed to contra-grav vehicles) designed using the **Fire, Fusion, & Steel Traveller** technical architecture rules are designed using the standard Terran parameters: a standard atmosphere and a 1G gravity field. However, aircraft may be designed to fly in conditions other than these. Ownership of **Fire, Fusion, & Steel** is necessary to use the material presented in this sidebar.

Aircraft may only fly in thin, standard, or dense atmospheres (codes 4-9). If an aircraft (fixed or rotary-wing) is intended to be able to operate in thin or dense atmospheres (or both) in addition to standard atmospheres, multiply its airframe cost by 1.5 to allow for reconfigurable or variable geometry intake ramps, lift devices, etc. (Note that the air-breathing engines and power plants installed in these aircraft are perfectly capable of functioning in thin and dense atmospheres with the above modifications to the aircraft.)

In addition, multiply rotary wing rotor assembly mass by 2 if they are to function in another atmosphere type in addition to standard. This provides them with the additional gearing required to allow them to be fitted with different rotor assemblies for different atmosphere types. Each additional set of rotors masses 0.25 times the mass of the modified multi-atmosphere rotor assembly. These extra rotor sets will have to be stored and transported separately at a volume in m^3 of 20 times their mass in tonnes. Cost is calculated normally based on rotor assembly type.

An aircraft's airframe will yield different maximum and minimum speeds in different atmosphere types, and this must be examined. It may be that some aircraft can no longer fly, as they can no longer meet the minimum speed required to stay in the air in a thin atmosphere, for example. Maximum, cruising, and NOE speeds must be recalculated based on these new numbers, and aircraft with drag points calculate their new speeds down from these new maxima using the normal procedure. The new minimum speeds will change take-off and landing distances as well.

Note that while dense atmospheres "slide the performance window down" by reducing minimum and maximum speeds, thin atmospheres narrow the permissible performance bands. This is because the speed of sound is lower in thin atmospheres, and airframe maximum speed is based on its ability to handle the compression phenomena associated with the speed of sound. (The other side of this is that denser atmospheres provide more lift, hence lower stall speeds, while thinner atmospheres provide less lift so require greater speeds to remain airborne.)

Note also that this table uses a single average value for each of thin and dense atmospheres. The actual density of any atmospheres varies within a range, so in reality, these numbers would be different for each and every world, even those classified by **Traveller** as having the same atmosphere type. As the purpose of these rules is to allow aircraft to be relatively quickly converted from one world type to the next, it would be criminally stupid to attempt to calculate exact numbers for each individual world. Instead, for the purposes of these rules (and in the interest of universal mental health) any world of a given atmosphere code yields the same performance as any other world with the same code. The value used for thin atmospheres is 0.6 atmospheres and the value for dense is 2.0 atmospheres.

Airframes

	Thin (4, 5)		Standard (6, 7)		Dense (8, 9)	
Type	*Min*	*Max*	*Min*	*Max*	*Min*	*Max*
Simple	250/125	270	150/75	320	75/40	160
Autogyro	65/—	200	40/—	200	20/—	100
Fast Subsonic	265/135	680	160/80	800	80/40	400
Transonic	300/150	940	180/90	1100	90/45	550
Supersonic	465/235	2400	280/140	2800	140/70	1400
Hypersonic	585/290	4300	350/175	5000	175/90	2500
Wing-in-ground	125/—	400	75/—	400	40/—	200

unsuitable as a colony site and the group should move on.

If the task fails, the characters receive a false negative reading. (For this reason it is wise for the PCs to make several atmospheric study tasks at various locations to weed out potential false readings.) The referee should roll on the Atmospheric Contaminants Table and not reveal the effect if a contaminant is present until the characters leave the ship and breathe the local air. Catastrophic failure indicates there is a delayed action contaminant that will affect humans beginning 3D weeks after exposure.

ATMOSPHERIC CONTAMINANTS

1D10	*Contaminant*
1	Allergens
2	Fungi (F)
3	High Carbon Dioxide
4	High Carbon Dioxide
5	High Oxygen
6	High Oxygen
7	Low Oxygen
8	Microorganisms (F)
9	Nitrogen Compounds (F)
10	Sulfur Compounds (F)

Contaminant Results: On the table above, the notation (F) indicates that a filter mask is required. Colonists may adapt to other contaminants using the acclimatization rules found in the Atmospheric Pressures section above. See the listing for the precise contaminant below to find any modifications to be used with the acclimatization and physiological effects rules.

Allergens: Roll 1D10 again and multiply the result by 10. This indicates the percentage of humans who react to airborne allergens with mild to severe respiratory symptoms. Local inhabitants may have adapted to these allergens. If the characters are already having to become acclimatized to the atmosphere because of differing atmospheric pressures, the presence of allergens adds no additional difficulty to this.

If, however, the characters are from an atmosphere of identical pressure, they will need to undergo the acclimatization procedures for this world. However, all acclimatization rolls are made with a –1 Diff Mod, and the characters start at Stage 2. Until acclimatized, all physiological rolls are also made with a –1 Diff Mod in addition to any other applicable mods. These modifiers may make these rolls so routine that the referee may elect to dispense with them altogether.

Fungi: Atmosphere-borne fungi harmful to humans are present. They attack the mucous membranes of the mouth and throat, and invade the lungs causing eventual suffocation. Some strains may attack the skin. Filter masks are needed to remove them from breathing air.

High Carbon Dioxide: This produces rapid breathing and a suffocating effect. At moderate concentrations it can be tolerated over time as long as sufficient oxygen is present.

If the characters are already having to become acclimatized to the atmosphere because of differing atmospheric pressures, the presence of high carbon dioxide adds no additional difficulty to this.

If, however, the characters are from an atmosphere of identical pressure, they will need to undergo normal acclimatization procedures and physiological effects rolls for this world.

High Oxygen: The partial pressure of oxygen in the atmosphere is significantly higher than is typical. This produces symptoms similar to those of persons attempting to become acclimatized to higher pressure atmospheres.

For acclimatization purposes, treat the atmosphere as being one pressure level higher than its actual pressure would indicate (i.e., a thin atmosphere with high oxygen would be treated as a standard atmosphere, a standard atmosphere with high oxygen would be treated as a dense atmosphere, and a dense atmosphere with high oxygen would be one step above a normal dense atmosphere, two steps above a standard atmosphere, and three steps above a thin atmosphere).

Air-Breathing Power Plants in Tainted and Inhospitable Atmospheres: All of the chemical power plants and jet self-contained thrusters presented in **Fire, Fusion, & Steel** (pages 63 and 70) are "air breathers," i.e., require an outside source of oxygen to function. These plants and thrusters are all defined using a standard atmosphere as their baseline, and require the following considerations to me met in order to function in other atmospheres.

All air-breathing power plants include fittings for filters for use in tainted atmospheres at no additional cost. (Certain environments, such as sandy deserts, may also require such filters.) When fitted, these filters cost 0.01 times the cost of the power plant and have negligible mass and volume. While these filters are fitted, multiply maintenance points of the vehicle by 1.2.

Air breathing power plants may also be modified to function in tainted atmospheres by carrying their own on-board oxygen supplies (which also allows the plant to function in vacuum, trace, exotic, corrosive, or insidious atmospheres). Any air-breathing vehicle using liquid hydrogen for fuel may modify its fuel tankage to carry half liquid oxygen and half liquid hydrogen. Such a vehicle may then operate in vacuum, trace, exotic, corrosive, or insidious atmospheres, or in tainted atmospheres without filters, as it has no need for external sources of oxygen. However, its rate of fuel consumption is doubled.

This modification costs Cr50 per cubic meter of fuel capacity, and does not prevent the vehicle from using the full tank for liquid hydrogen for normal external oxygen operations.

Other noteworthy effects are present, such as the fact that fires will burn more rapidly than would be the case in a standard 20% oxygen environment. The effects of fires should be more pronounced, but the seriousness of this effect is also left up to the referee.

Low Oxygen: The partial pressure of oxygen in the atmosphere is significantly lower than is typical. This produces symptoms similar to those of persons attempting to become acclimatized to lower pressure atmospheres.

For acclimatization purposes, treat the atmosphere as being one pressure level lower than its actual pressure would indicate (i.e., a dense atmosphere with low oxygen would be treated as a standard atmosphere, a standard atmosphere with low oxygen would be treated as a thin atmosphere, and a thin atmosphere with low oxygen would be one step below a normal thin atmosphere, two steps below a standard atmosphere, and three steps below a dense atmosphere).

Another noteworthy affect of a low oxygen concentration is the fact that fires will not burn as well. They will be harder to start, and will burn slower once started than would be the case in a standard 20% oxygen environment. The effects of these slower, less dangerous fires is left up to the referee.

Microorganisms: Viruses and/or bacteria are present that will attack the respiratory or neurological system within 1D6 days. Filter masks are required to remove these from the air.

Nitrogen Compounds: The atmosphere contains a considerable portion of harmful nitrogen compounds. These are often the result of industrial pollution, especially resulting from the use of hydrocarbon fuels, interacting with ultraviolet stellar radiation. Filter masks are required to allow humans to avoid the deleterious effects of these chemicals.

Nitrogen compounds may be present on a depopulated or regressed industrial world. Nitrogen compounds absorb the blue-violet end of the visible light spectrum giving the atmosphere a characteristic brownish-yellow haze.

Sulfur Compounds: Sulfur compounds are present in the atmosphere, usually from volcanic activity on the world. Filter masks are required to screen out these irritating compounds to allow humans to live in such an atmosphere. Lung damage will result if these compounds are breathed over time. Some sulfur compounds, such as sulfur dioxide and hydrogen sulfide, have a repulsive smells as well.

Planetary Density & Gravity

If the players have not yet determined the planet's density and gravity from orbit, they will do so as soon as they land. (Use the World Density and World Gravity tables on page 87 to do this.) Note that a dense, relatively high gravity world usually indicates the presence of heavy metal deposits, making the planet a potentially valuable mining site.

Physiological Effects: As with atmospheres, the different physical demands placed on a body by higher than accustomed gravity can have physiological affects on characters. These effects are described in the **TNE** basic rule book, pages 197-198.

Temperature & Weather

Temperature: Referees must have completed a planetary temperature worksheet if the PCs intend to conduct a detailed survey which includes temperature evaluation. The PCs may take simple temperature readings in any hex they like, and thereby rapidly put together a temperature profile of the world. By consulting the worksheet, the referee can provide this data to the players on a hex-by-hex basis, or the players may be provided with a correct copy of the table provided they succeed at a Formidable Survey task. The difficulty level of this task is reduced one level for each 10 planetary hexes in which the PCs take temperature readings.

Gravity and Aerodynamic Aircraft Performance

Traveller does not focus on a world's gravity *per se*, but primarily on the density of its atmosphere, which is a reflection of its gravity. Players and referees should not feel compelled to worry about gravity effects on aircraft so long as they address the atmospheric requirements above.

However, some players who use the **Fire, Fusion, & Steel** technical architecture book to design aircraft may feel compelled to account for different gravities when calculating aircraft performance. **FF&S** assumes a standard atmosphere and a standard 1G field in its design sequences. In order to account for gravities other than 1G, multiply the aircraft weight by the local gravity before calculating G-Rating, Speed, and Take-off and Landing rolls. Calculate glide ratios normally, and then divide the result by the local gravity in Gs. In G-fields of greater than one, multiply normally-calculated maintenance points by the gravity in Gs, as more maintence is required to watch for and repair stress fractures, etc.

The temperatures will also be used later on when determining the suitability of planetary hexes for agriculture.

Weather: Weather is the result in large degree to two characteristics of the world: its primary star and the world's axial tilt. A world's star pumps energy into its ecosphere in the form of solar radition, and the more energetic the star, the more energetic and violent the resulting weather.

Likewise, the greater the axial tilt of a world, the greater the temperature difference that builds up with regard to that solar heating between the northern and southern hemispheres. Consequently, on a world with an extreme axial tilt, there is a near constant massive and violent movement of air from the cold winter hemisphere to the warm summer hemisphere. Conversely, there is little air movement on a world with little tilt that is evenly warmed and cooled.

Consult the Weather Factors table for a world's star and axial tilt characteristics to come up with a total weather factor number by adding the factors together (as many as three may apply to a given world). These factors may be used again later for local weather and agricultural richness, and also in the Colonial Economic model for random events and possible modifications to infrastructure maintenance (see page 35).

WEATHER FACTORS

+4 if system's star is type A
+2 if system's star is type F
–1 if system's star is type K
–2 if system's star is type M
–2 if axial tilt is zero.
–1 if axial tilt is 1-10 degrees
+1 if axial tilt is 20-29 degrees
+2 if axial tilt is 30-44 degrees
+4 if axial tilt is greater than 45 degrees
+1 if UWP hydrographic code 5+

Environmental Research and Testing

The PC survey team needs to conduct soil tests, collect soil samples, plant samples, and animal samples to learn about the local ecology and whether the soil is suitable for crops and domestic grazing animals. They must also test mineral outcroppings to determine if exploitable mineral deposits are present.

Mineral Testing: Mineral samples need to be tested to determine

their constituent metallic or organic elements. As discussed in the sidebar on uncertain tasks, they may be attempted more than one time to reduce the possibility of false positive or negative readings.

For purposes of the colonial economic model (see Chapter 4), the results of these tests are limited to three details: the presence or absence of fossil fuels and radioactives, and the extent to which the world has already had its mineral resources exploited by previous habitation. The results of these tests will be used again later in the survey procedure. Both tasks are Impossible: Geology, but should be reduced in difficulty for additional attempts as discussed in the Uncertain Tasks sidebar on page 11. Each test should take approximately one day once the team has arrived in the area to be tested. (Thus the quality of transportation available to the survey team will affect the time required by controlling how rapidly they can move from one site to the next.)

Fossil Fuels: Fossil fuels are the remains of long-dead lifeforms, mostly plants, that have been buried and transformed by geological processes into hydrocarbon fuels. The presence of fossil fuels (coal, oil, natural gas) require for the world to have sustained organic life long enough ago that it has since been geologically transformed. On worlds that cannot support life, or have not existed long enough for these conditions, fossil fuels cannot exist. The result of this test is a simple yes/no test for the planet as a whole.

Success at the uncertain Survey task allows the referee to report the correct answer (yes or no to presence of fossil fuels) to the PCs. Failure requires the referee to report a false result.

The table below assumes a primary star of luminosity class V and an atmosphere of 2-9.

Star Type	*Exceed on 2D6*
A	12+
F	10+
G	7+
K	6+
M	5+

Atmosphere DMs:
2-3: –2
4-9: 0

Hydrographic DMs:
0: –2
1-2: –1
3-8: 0
9-A: –1

Radioactives: This is a simple yes/no result, with radioactives being present on a 2D6 roll of 9+. DM –3 if low density planet, +3 if high density, –2 if primary star K or M.

Prior Exploitation: This test is based on the current or pre-Collapse population and tech level of the world, whichever is greater. Note that these figures may not be known to the survey team, but they need not be known for the team to obtain the correct answer, as the answer is obtained by actually sampling existing mineral deposits.

The referee consults the table below and conducts any necessary die rolls to determine the exploitation multiplier. This multiplier is used later in this chapter to modify the raw materials richness to account for previous inhabitants having already removed non-renewable resources.

Success at the uncertain Survey task allows the referee to report the correct number to the PCs. Failure requires that the referee report a false number.

The values obtained from the table below must be multiplied by 0.1 to create the final multiplier, and all results of greater than 1.0 become 1.0. Thus in the case of a world with a population A and TL of 16, a D6 result of 6 is obtained, yielding an outcome of (7–6=) 1. The final prior exploitation multiplier is therefore 1×0.1=0.1.

In the case of a population A, TL 11 world, the result is (12–1=) 11, 11×0.1 = 1.1, and this is corrected to the upper limit of 1.0.

	Population				
TL	*0-6*	*7*	*8*	*9*	*A*
0-7	—	—	—	—	15-D6
8	—	—	—	15-D6	14-D6
9	—	—	15-D6	14-D6	13-D6
10	—	15-D6	14-D6	13-D6	12-D6
11	15-D6	14-D6	13-D6	12-D6	11-D6
12	14-D6	13-D6	12-D6	11-D6	10-D6
13	13-D6	12-D6	11-D6	10-D6	9-D6
14	12-D6	11-D6	10-D6	9-D6	8-D6
15	11-D6	10-D6	9-D6	8-D6	7-D6
16	10-D6	9-D6	8-D6	7-D6	6-D6

Soil Testing: The survey team must also test the soil for human agricultural use. This test determines if the soil of the world contains materials that will prevent human agriculture. Such materials include heavy metals or salts in the soil, or biological organisms that are hostile to human-compatible crops.

The task is uncertain, Impossible: Chemistry *and* Biology, with the normal difficulty modifiers for multiple task attempts as discussed in the Uncertain Task sidebar on page 11.

The referee rolls secretly on the table below and records the result. Success in the PCs' task indicates that the referee can report the correct result to them. Failure requires that they be given a false result.

The result on this table is used when rolling for the agricultural richness rating for all of the world's planetary hexes in the Goal-Oriented Survey section below.

1D6	*Soil Contaminants*
1	None, no mod on Agricultural Richness table
2	None, no mod on Agricultural Richness table
3	None, no mod on Agricultural Richness table
4	Mild, –4 DM on Agricultural Richness table
5	Moderate, –6 DM on Agricultural Richness table
6	Severe, –10 DM on Agricultural Richness table

Biological Compatability: The survey team must also determine if local plant life will be edible and/or compatible with human agricultural activity. This uncertain task is Formidable: Biology, with the usual diff mods for additional attempts. Each such attempt requires one week. Otherwise this procedure is handled the same as soil testing above.

1D6	*Agricultural Compatibility*
1	Import Dominant, +2 on Agricultural Richness table
2	Import Compatible, no mod on Agricultural Richness table
3	Import Compatible, no mod on Agricultural Richness table
4	Import Compatible, no mod on Agricultural Richness table
5	Local Dominant, –1 on Agricultural Richness table
6	Local Dominant, –2 on Agricultural Richness table

GOAL-ORIENTED SURVEY TASKS

The conduct of goal-oriented survey tasks indicates that actual sites for habitation are being explored. This is usually done only after the general survey tasks are completed and it has been determined that there are no major obstacles to colonization (such as lack of fossil fuels or other mineral resources, unsuitable temperature or weather patterns, etc.). The goal-oriented survey provides the parameters that are used in the Colonial Economic Model presented in Chapter 4, and is therefore a necessary condition to the establishment of any kind of settlement.

A goal-oriented survey task consists of the in-depth examination of a single planetary hex by the survey team, but this single survey task provides all of the data required for the economic model, rather than requiring separate tasks for each piece of data. However, because of the length of time required for the goal-oriented task, the planetary hex to be surveyed should be carefully chosen based on promising characteristics (for example, it is probably not worthwhile to survey a desert hex). When a survey is conducted, all of the information below is generated and presented to the players if the task is successfully completed.

Hex Scale

Goal-oriented survey tasks are resolved on the scale of *planetary hexes*. Planetary hexes are the individual hexes shown on the "Global Data View" world maps (see pages 59 and 78 of this book for examples). Because these maps are designed to fit different-sized worlds into one standard format, these hexes do not have a constant scale, but vary in scale based on the size of the planet that is illustrated.

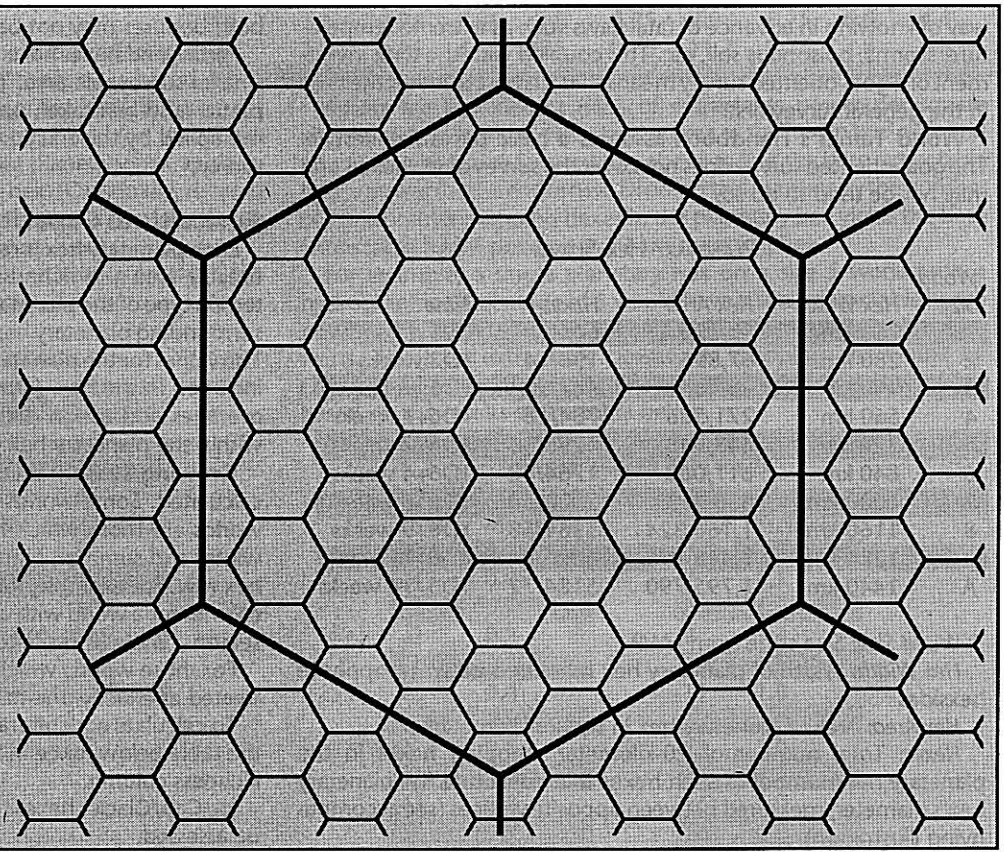
However, for the detailed colony and bootstrap campaigns that are presented in the **World Tamers Handbook**, these large planetary hexes are broken down into smaller hexes for better resolution. Unlike the planetary hexes, the smaller hexes used for these adventures have a constant scale of 20 kilometers from hexside to hexside, and are called *20-kilometer mapping hexes*, or mapping hexes for short. Because of the variable size of planetary hexes, the number of mapping hexes that fit into each planetary hex varies by planet. The Planetary Hex Survey table below and accompanying illustration sidebar show how planetary hexes of varying sizes are broken down into mapping hexes to allow referees to create the more detailed maps that are required for laying out colonies, tracking the progress of a war in a bootstrap campaign, etc.

Terrain Types

The two hex scales (planetary and mapping) also use two separate but related terrain scales. The scale used for planetary hexes has eight types, corresponding to the predominant terrain found in the hex. These do not include artificial additions such as starports, cities, etc.

The terrain "palette" used for 20-km mapping hexes consists of a greater variety of types. The terrain types used for these mapping hexes is identical to the terrain types used when generating animal encounter tables as listed in the TNE basic rulebook, page 215.

When referees and other world designers create the detailed 20-km hex maps, the terrain that they place in these smaller hexes is governed by the terrain type of the planetary hex itself. The detailed terrain types subsumed within the planetary hex terrain types are listed on the Terrain Scale Conversion table, below. Of course, any planetary hex can have unique or unexpected terrain types within it, so this table should serve primarily as a guideline.



TERRAIN SCALE CONVERSION

Planetary Hex	*20-km Mapping Hex*
Sea	Surface, Shallows, Depths, Bottom, etc.
Mixed	Clear, Rough, Forest, River, Swamp, Marsh
Steppe	Prairie, River
Ice Cap/Glacier	Glacier
Desert	Desert
Badlands	Broken, Rough, River, Mountain
Tundra	Clear, Rough, River
Jungle	Jungle, River

Note that mixed terrain includes most terrain thought of as habitable by humans. Areas inhabited by humans and used for agriculture, i.e., cities, suburbs, and farms, are primarily mixed terrain hexes that have been cleared for development. On the more detailed scale, these hexes would be mostly clear and forest hexes.

The hex grid illustrated here is for use with the Planetary Hex Survey table at right. The example shows the 20-kilometer hexes within a single planetary hex of a UWP size 1 world. By consulting the table, we see that this hex has a total of 64 hexes in it, and has a vertex-to-vertex diameter of eight such 20-kilometer hexes. On the hex grid, this diameter is rendered as seven full hexes plus two half hexes, one at each end, for a total of eight.

Maps can be made showing the 20-kilometer hexes within a planetary hex by using the chart below with a sheet of blank hex paper and a ruler. Find the correct diameter for a given size planetary hex, and count that number of hexes off on the grid, marking the hex vertices, and then connect them by using the ruler. Use the sample UWP size 1 grid here as a guide, so that all hex diameters half a half hex on each end. Thus a Size 2 world has a diameter of 14 hexes (13 and two half-hexes), a Size 3 world has a diameter of 22 hexes (21 and two half-hexes), and so on.

The Goal-Oriented Survey Task

Unlike many of the general survey tasks earlier in this chapter, it is possible to conduct the goal-oriented survey so that success is guaranteed, i.e., the results delivered to the players are guaranteed to be the correct results generated by the referee.

The price of this exactness is a large time component. The Planetary Hex Survey table shows the time required to survey a single planetary hex for all UWP world sizes. There are certain factors than can reduce this required time, and these are listed in the box at right. Among these factors are the option to speed up the survey by making it into an uncertain task, which means that the survey team can bring home bad data. Although the survey task starts out as an automatic task, it is treated as having a base level of Easy for purposes of adding time-saving difficulty modifiers.

When rolling for this task, the referee should total up the party's relevant survey assets (see next paragraph) and divide by the total number of such assets possessed by the party to find the average asset number to roll against.

The survey team required for this task (whether it is automatic or not) should be at least four personnel, and these personnel should have significant skills in Map, Navigation, Observation, Tracking, Biology, Chemistry, Geology, Meteorology, Xeno-Biology, Sensors, and Survey (referee's discretion). It is assumed that the team is equipped with all basic survey equipment, testing kits, hand-carried sensors, etc.

Although PCs can theoretically go to an unexplored world and perform a goal-oriented survey task first, with the knowledge that the results will be perfectly correct, this is not the bargain it might seem. Without first performing the general survey, the players will have no world map, and will choose planetary hexes blindly, and will have no way of knowing in advance of fatal flaws such as extreme temperature, storms, poisonous soil, etc. This coupled with the time investment of a goal-oriented survey means that it is best to invest the time in the general survey first.

World Tamer's Handbook assumes a basic terrestrial lifestyle. The goal-oriented survey does not cover the survey of sea hexes, and may not be used to do so.

Time Reductions for Planetary Hex Survey

Factor	*% Decrease*
Diff Mod increase: (from Easy, i.e., one diff mod makes it Average, two diff mods makes it Difficult, etc.)	10% each
For each team member above four	1% each, to a maximum of 6%
For each tech level above 8	½% each
One or more labs available aboard ship or on ground	10%
Spacecraft	10%
Active EMS on Spacecraft	5%
Passive EMS on Spacecraft	5%
Densitometer on Spacecraft	5%
Neural activity sensor available to survey party	5%
Self-propelled ground vehicles for all party members	5%
Grav vehicles for all party members	10%

Planetary Hex Survey

World Size	*Hex Width*	*Hex Area*	*Hexes*	*Time*
1	160 km	22,170	64/8	1D6 days
2	280 km	67,896	196/14	1D2 weeks
3	440 km	167,663	484/22	1D6 weeks
4	560 km	271,586	784/28	1D6+1 weeks
5	720 km	448,948	1296/36	1D6+2 weeks
6	840 km	611,068	1764/42	1D6+4 weeks
7	1000 km	866,025	2500/50	1D6+6 weeks
8	1160 km	1,165,324	3364/58	1D6+9 weeks
9	1280 km	1,418,896	4096/64	1D6+11 weeks
A	1440 km	1,795,790	5184/72	1D6+14 weeks

World Size: Size code from UWP

Hex Width: Width of planetary hex measured between opposite hexsides

Hex Area: Area of planetary hex in square kilometers

Hexes: Total number of 20-kilometer mapping hexes in the planetary hex/number of such hexes that constitute the planetary hex's diameter, measured between opposite vertices (see accompanying illustration)

Time: Base time to conduct a goal-oriented survey of a single planetary hex, as modified by the factors on the Time Reductions table above.

Notes to Time Reductions Table: The team's tech level is assumed to be that of the world which sent/equipped them, although referees may make allowances for PC teams which have carefully equipped themselves with a wide variety of higher TL equipment. Spacecraft is a dedicated spacecraft used by the party as part of the survey, and must have a tech level at least equal to the rated TL of the survey team. If the ship's TL is lower, use the ship bonus but not the party's TL bonus. More than one ship adds no additional bonuses. Listed sensors are those aboard this spacecraft. The vehicle requirement is that the total vehicle capacity is equal to the party size, for example two air rafts each with seating for four would be sufficient for a party of eight, but not for a party of ten. The vehicle criteria are either/or, both bonuses may not be taken.

Partial land hexes have their survey time reduced because of their smaller surveyable area. The referee should judge the fraction of a partial land hex taken up by land, and the survey time should be multiplied by this fraction to obtain the final time required for the survey.

Agricultural Capacity

Each planetary hex is rated for its agricultural capacity in terms of useable area and richness. This capacity is based primarily on the terrain type of the planetary hex itself, but is also modified by the six surrounding planetary hexes (or in the case of mountains, hexsides). The values for the planetary hex apply to every 20-km mapping hex included in the hex. (Optionally, referees may use these values as averages and assign different values to different mapping hexes within the planetary hex.)

Growing Season: Each world must also have its growing season calculated. Some worlds are treated as having no seasons. These worlds are those which have no temperature difference between winter and summer. Note that this distinction varies with latitude/hex row. For example, look at the axial tilt table on page 85, in the column for a world with a 9-12° axial tilt. Hexes in rows 1-5 have no seasons, while hexes in rows 6-12 do.

For those worlds which do have seasons, the growing season is treated as exactly one-half of its year as calculated on page 83.

To calculate agricultural capacity of a planetary hex, roll twice on the table below, once in the Useable Area column and once in the Richness column.

Ice Cap/Glacier hexes have no agricultural capacity and need not be assessed.

D10	Useable Area	Richness
–5	0%	0.05
–4	5%	0.1
–3	10%	0.2
–2	15%	0.3
–1	20%	0.4
0	25%	0.5
1	30%	0.6
2	35%	0.7
3	40%	0.8
4	45%	0.9

Total Weather Factors +4–+5: –2
Total Weather Factors +6–+8: –3
Soil Contaminants: DM as obtained on page 18
Biological Compatability: DM as obtained on page 18
Summer Maximum Temp 50°C+: –10
Summer Maximum Temp 10°C–: –10
Winter Minimum Temp 10-50°C: +2
Growing Season (one-half of year) over 8 months: –2
World has no seasons: –2

Raw Materials Capacity

Each planetary hex is rated for its raw materials capacity in terms of useable area and richness. This capacity is based primarily on the terrain type of the planetary hex itself, but is also modified by the six surrounding planetary hexes (or, in the case of mountains, hexsides). The values for the planetary hex apply to every 20-km mapping hex included in the hex. (Optionally, referees may use these values as averages and assign different values to different mapping hexes within the planetary hex.)

Roll twice on the table below, once in the Useable Area column and once in the Richness column.

D10	Useable Area	Richness	D10	Useable Area	Richness
–5	—	1	6	30%	50
–4	—	2	7	35%	55
–3	—	5	8	40%	60
–2	—	10	9	45%	65
–1	—	15	10	50%	70
0	0%	20	11	55%	80
1	5%	25	12	60%	90
2	10%	30	13	65%	100
3	15%	35	14	75%	110
4	20%	40	15	80%	120
5	25%	45	16	85%	150

Die Modifiers: Useable Area Only
Glacier hex: No useable area; do not roll
Badlands hex: +2
Per neighboring mountain hexside: +1
Weather factors +6 or greater: +2

Die Modifiers: Richness Only
Steppe hex: –1
Desert hex: –2
World has fossil fuels: +4
World has low density: –3
World has high density: +3
World has radioactives: +1

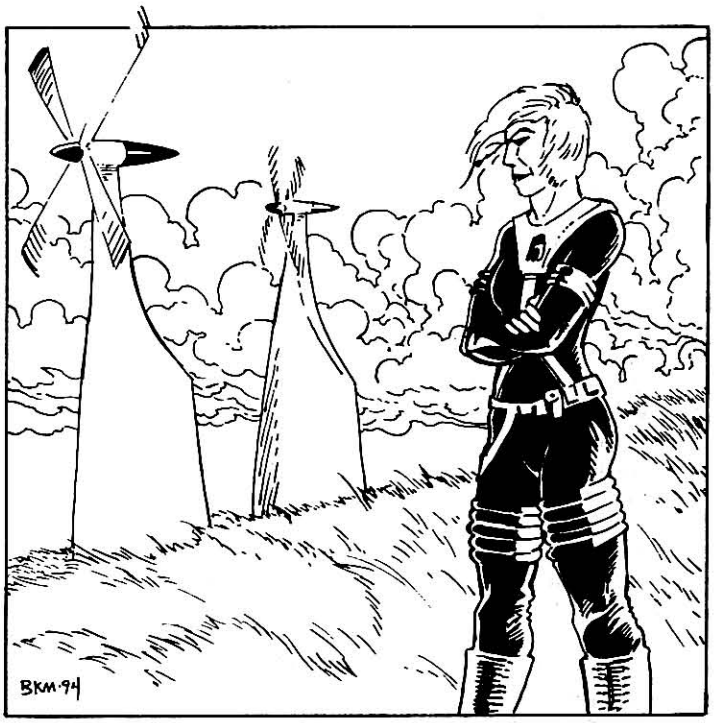
Prior Exploitation: Remember to multiply the richness value of the hex by the value obtained earlier for prior exploitation. This step reduces the richness value to reflect the fact that much of the resources have already been removed.

Extractable Hydro Power

Each planetary hex has a certain amount of "free" hydro power available in it. This "free" power must then be extracted by mechanical means, such as water wheels, dams and hydroelectric turbines

The base hydro power in a planetary hex is obtained by indexing a world's size and hydrographic percentage on the Base Hydro Power table. The hex's base hydro power is then modified by a multiplier obtained by rolling on the Hydro Power Multiplier table, which incorporates the effects of different hex types.

Base Hydro Power



World Size	World Hydrographic Percentage 1	2	3	4	5	6	7	8	9	A
1	0.15	0.375	0.525	0.75	1.125	1.35	1.125	0.9	0.6	0.3
2	0.25	0.625	0.875	1.25	1.875	2.25	1.875	1.5	1	0.5
3	0.4	1.0	1.4	2.0	3.0	3.6	3.0	2.4	1.6	0.8
4	0.5	1.25	1.75	2.5	3.75	4.5	3.75	3	2	1.0
5	0.6	1.5	2.1	3.0	4.5	5.4	4.5	3.6	2.4	1.2
6	0.8	2.0	2.8	4.0	6.0	7.2	6.0	4.8	3.2	1.6
7	0.9	2.25	3.15	4.5	6.75	8.1	6.75	5.4	3.6	1.8
8	1.0	2.5	3.5	5.0	7.5	9.0	7.5	6.0	4.0	2.0
9	1.1	2.75	3.85	5.5	8.25	9.9	8.25	6.6	4.4	2.2
A	1.3	3.25	4.55	6.5	9.75	11.7	9.75	7.8	5.2	2.6

Values are in kilowatts (kW) of extractable power per square kilometer. Multiply this value by the area of the hex in km² as found on the Planetary Hex Survey table above to find the base extractable hydro power for the entire hex. Dividing this number by the number of 20-kilometer mapping hexes in the planetary hex yields the base extractable hydro power per 20-km mapping hex.

For example, a single planetary hex on a size 5 world with a hydrographic percentage of 6 would have a total extractable hydro power of (5.4 × 448,948 =) 2,424,319 kilowatts, or 2424.3 megawatts. The base extractable power per mapping hex would be (2424.3 + 1296 =) 1.87 megawatts. This base power is modified based on the results of the table below.

Hydro Power Multiplier

D10	Multiplier	D10	Multiplier
–5	0.01	6	1.0
–4	0.05	7	1.1
–3	0.1	8	1.2
–2	0.2	9	1.4
–1	0.3	10	1.6
0	0.4	11	1.8
1	0.5	12	2.0
2	0.6	13	3.0
3	0.7	14	4.0
4	0.8	15	5.0
5	0.9	16+	6.0

DIE MODIFIERS FOR HYDRO POWER MULTIPLIER TABLE

Hex Type	*Target Hex*	*Per Neighboring Hex /Hexside (Max)*
Mixed	+2	–1 per Steppe or Desert hex (–6) +2 per Mountain hexside (+6) +1 per Sea hex (+3)
Steppe	–5	–1 per Steppe or Desert hex (–6) +1 per Mountain hexside (+3) +1 per Sea hex (+3)
Ice Cap/Glacier	None*	None
Desert	–8	–1 per Steppe or Desert hex (–6) +1 per Mountain hexside (+3) +1 per Sea hex (+3)
Badlands	0	+2 per Mountain hexside (+6) +1 per Sea hex (+3)
Tundra	0	–1 per Steppe or Desert hex (–6) +1 per Mountain hexside (+3) +1 per Sea hex (+3)
Jungle	+2	+2 per Mountain hexside (+6) +1 per Sea hex (+3)
Island**	–5	None

Target hex is the planetary hex which is itself the target of the goal-oriented survey. The neighboring hexes are the six surrounding hexes. Hexes on the opposite side of mountain hexsides are not used for these calculations; the mountain hexside takes precedence as neighboring terrain no matter what is on the other side. Only full sea hexes count as sea hexes for purposes of the neighboring hex DMs; half-sea hexes count as land hexes of the appropriate land terrain type. Ice cap sea hexes also do not count as sea hexes for these DMs. Note that the chart indicates maximum DMs permitted from each terrain type.

*Hex has no extractable hydro power, regardless of surrounding hexes. Do not roll on table, enter "0" for hex's hydro potential.

**Any island which fits completely within one planetary hex uses this DM regardless of its terrain type.

Extractable Wind Power

As with hydro power, each planetary hex has a certain amount of extractable wind power available in it. The base wind power in a planetary hex is obtained by indexing a world's atmophere and hydrographic codes on the Base Wind Power table. The hex's base wind power is then modified by a multiplier obtained by rolling on the Wind Power Multiplier table, which incorporates the effects of different hex types.

BASE WIND POWER

World	*——World Atmosphere Digit——*			
Hydro	*0-3*	*4-5*	*6-7*	*8-9*
1	—	110	160	290
2	—	150	220	400
3	—	200	280	500
4	—	240	340	610
5	—	280	400	720
6	—	240	340	610
7	—	200	280	500
8	—	150	220	400
9	—	110	160	290
A	—	70	100	180

Values are in kilowatts (kW) of extractable power per square kilometer. Multiply this value by the area of the hex in km² as found on the Planetary Hex Survey table above to find the base extractable wind power for the entire planetary hex. Dividing this number by the number of 20-kilometer mapping hexes in the planetary hex yields the base extractable hydro power per 20-km mapping hex. This base power is modified based on the results of the table below.

WIND POWER MULTIPLIER

D10	*Multiplier*	*D10*	*Multiplier*
–2	0.2	8	1.2
–1	0.3	9	1.3
0	0.4	10	1.4
1	0.5	11	1.5
2	0.6	12	1.6
3	0.7	13	1.7
4	0.8	14	1.8
5	0.9	15	1.9
6	1.0	16+	2.0
7	1.1		

DIE MODIFIERS FOR WIND POWER MULTIPLIER TABLE

Hex Type	*Target Hex*	*Per Neighboring Hex/Hexside (Max)*
Mixed	–3	+2 per Mountain hexside (+6) +1 per Sea hex (+3)
Steppe	+1	+1 per Steppe hex (+6) +1 per Mountain hexside (+3) +1 per Sea hex (+3)
Ice Cap/Glacier	+1	+1 per Ice Cap/Glacier hex (+6) +1 per Mountain hexside (+2)
Desert	+1	+1 per Desert hex (+6) +1 per Mountain hexside (+3) +1 per Sea hex (+3)
Badlands	–3	+2 per Mountain hexside (+6) +1 per Sea hex (+3)
Tundra	+1	+1 per Tundra hex (+6)
Jungle	–3	+1 per Mountain hexside (+3) +1 per Sea hex (+3)

Target hex is the planetary hex which is itself the target of the goal-oriented survey. The neighboring hexes are the six surrounding

hexes. Hexes on the opposite side of mountain hexsides are not used for these calculations; the mountain hexside takes precedence as neighboring terrain no matter what is on the other side. Only full sea hexes count as sea hexes for purposes of the neighboring hex DMs; half-sea hexes count as land hexes of the appropriate land terrain type. Note that the chart indicates maximum DMs permitted from each terrain type.

Compile Economic Model Data

For the purposes of a colony or bootstrap campaign, the most important thing about the planetary survey are the numbers that feed into the colonial economic model, such as the agricultural and raw materials richness, useable area, maintenance modifiers, etc. Compile a list of all such relevant figures from the goal-oriented survey so that they are easily referenced for the economic model.

It is also possible that these numbers will be unfavorable, and the planetary hex will be rejected for habitation. In this case, another goal-oriented survey will be necessary if the world is to be settled.

SURVEY AS ADVENTURE

The above passages concentrate primarily on the Survey as a means of gaining information about a world's suitability for future purposes, but referees may also wish to use the survey mission as a framework for a roleplaying campaign.

As each surveyed world can be radically different, this chapter can only give the broadest of outlines for the kind of preparations a referee will wish to make.

Mapping

Any world which will be surveyed requires a map, on at least the scale of the global data view. If the PCs will be exploring specific areas in more detail, the referee may wish to prepare maps on the continental data view or local data view scale, or require the players to fill these out in the course of their explorations. Blank versions of all three map scales are available in the **Traveller Players' Forms** booklet.

Weather

When adventuring or exploring on the world, roll 1D20 on the Weather Change table every 8 hours (two periods), and move up or down the indicated number of lines on the Weather Track. Consult the Weather Factors table and index the world's axial tilt, primary star, and hydrographic code. As many as three such factors may apply, and are added together to find the correct column on the Weather Change table.

Weather Factors

+4 if system's star is type A
+2 if system's star is type F
–1 if system's star is type K
–2 if system's star is type M
–2 if axial tilt is zero.
–1 if axial tilt is 1-10 degrees
+1 if axial tilt is 20-29 degrees
+2 if axial tilt is 30-44 degrees
+4 if axial tilt is greater than 45 degrees
+1 if UWP hydrogaraphics code 5+

Weather Types

Clear: Good visibility and light winds up to 20 kilometers per hour.

Overcast: The sky is over 50 percent overcast with light winds.

Windy: Winds are blowing at up to 70 kilometers per hour. Depending on terrain and climate, this may result in a dust or sand storm, white-out conditions in snow, or high waves on bodies of water (Treat as Poor Weather for Tactical Visibility rules, TNE page 309, in this case).

Increase all tasks using Aircraft and Watercraft skill by one difficulty level.

Storm: Rain or snow is falling depending on local temperature. Treat as Poor Weather for Tactical Visibility rules (TNE page 309).

Increase all tasks using Aircraft or Watercraft skill by one difficulty level.

Severe Storm: Precipitation (rain or snow, depending upon temperature) accompanied by high winds up to 70 kph. Treat as Very Poor Weather for Tactical Visibility rules (TNE page 309).

Increase all vehicular tasks by one difficulty level, and all tasks using Aircraft or Watercraft skill by two difficulty levels.

At the beginning of an eight-hour weather period following a severe storm, weather reverts to Storm before rolling for the new weather.

Weather Change

Weather Track

Clear
Overcast
Windy
Storm
Severe Storm
Catastrophic Storm

U#: Up the indicated number of lines on the weather track

—: No change on the weather track

D#: Down the indicated number of lines on the weather track

CO#: Center toward overcast the indicated number of lines (i.e., move the current weather toward overcast, regardless of whether this is up or down on the track)

Catastrophic Storm: Precipitation (rain or snow, depending upon temperature) with winds above 100 kph, destroying wooden structures and vegetation. Treat as Poor Weather for Tactical Visibility rules (TNE page 309). Personnel and livestock out-of-doors should roll a Difficult task vs. Agility to avoid injury, roll 1D6 for dice of damage to random body part. Vehicles are attacked with a penetration value of 5 on a 1D10 roll of 2 or less every five minutes. Increase all vehicular tasks by two difficulty levels, and all other out-of-doors tasks by one difficulty level.

At the beginning of an eight-hour weather period following a catastrophic storm, weather reverts to Storm before rolling for the new weather.

Animals

Animals will naturally be encountered during the course of moving about on a world, and these encounters can range from the amusing or interesting to the frightening and deadly.

The referee will want to prepare animal encounter tables suitable to the terrain that the PCs will be exploring, using the rules in TNE pages 207-217. These rules can be used to craft animals for a particular purpose, or to randomly generate animals. Particularly interesting, dangerous, or important animals can be designed or chosen from a randomly generated table to be developed in more detail. This detail could include specifics of the animal's behavior, lifestyle, habitat, etc., which will come into play when these creatures are encountered by the PCs.

Blank forms for this purpose are available in the **Traveller Players' Forms** book, and examples of completed animal encounter tables may be found on pages 66-67 and 80-81 of this book.

Most survey missions will also involve cataloging the types of animals that can be encountered in various regions, particularly those which are expected to be developed by follow-on colonists or bootstrap teams. In this case, the referee could require the players to discover all of the creatures included on the encounter table for the local terrain type by using a combination of Tracking and Observation skills. Once the creatures have been found, the players may determine their values on the animal encounter table by observing their behavior (Observation skill) or by examining dead or tranquilized animals with Biology or Xeno-Biology skills.

Inhabitants

Interaction with local natives is an unlimited topic, and has been the subject of entire books of **Traveller** adventures. In the context of a survey mission, however, PCs have the opportunity to conduct first contact missions, using skills like Liaison, Persuasion, Psychology, Observation, and Bargain to open hopefully friendly relations with the locals.

Diseases

Diseases can be encountered in a number of ways in a **Traveller** campaign, and can have varying effects on the victim. They can be contracted from contact with local inhabitants or animal life, drinking unpurified water, bites from infected animals, or breathing airborne microbes. In general, however, diseases which are compatible with human biology will be contracted by contacting local humans, and this is the assumption used by the model below. However, referees should feel free to institute other disease vectors should they feel the need.

The following disease rules are also used in conjunction with the Colony and Bootstrap campaigns found elsewhere in this book.

To determine if a disease is present during a random encounter with human NPCs, roll 2D6 and compare it with the Disease Encounter table. If the result is equal to or greater than the number corresponding to the local tech level, disease is present.

DISEASE ENCOUNTER

TL	*Disease number*
0-4	10+
5-11	11+
11-15	12+

Note that the tech level applies to the local community, not the overall world tech level. As an example in the Bootstrap campaign, the "disease present" number in the bootstrap base camp is 11+, reflecting the sanitation and disease control capabilities of the team's TL 9 home world, Oriflamme. At the same time, the "disease present" number in the cities and villages of So Skire is 10+, reflecting that world's low technology level.

Characters can also contract disease by drinking unpurified water. Disease is present on a 2D6 roll of 12+ in water not treated with boiling, a water filtration/distillation unit, or tablets from a water purification kit. Characters may attempt to detect the presence of disease in water by rolling an Average test vs. Survival, Medical (Diagnosis), or Biology.

If a disease is present, roll on the Disease Table to determine what kind of disease is present and the basic data about its effects.

The result will indicate the type of disease present, its probability of infection, the length of its incubation period, the length the disease takes to run its course, the days it takes for the patient to be fully recovered, the probability of recovery, the probability of death if recovery fails, and the impact the disease has on the patient's fatigue level during recovery.

Infection: To determine whether an individual is infected, roll an Average: CON task. Add the Infection Number for the disease plus the current fatigue level number, if any, to the die roll result before

DISEASE TABLE

2D6	*Disease*	*Infection Number*	*Incubation (days)*	*Phase I (days)*	*Phase II (days)*	*Recovery (days)*	*Recovery Number*	*Death Number*	*Rec. Fatigue Treat./No Treat.*
2	Crippling	3	21	14	7	140	25	9	0/2
3	Intestinal	5	1	3	3	28	21	2	2/3
4	Nerve	3	5	10	20	120	22	5	1/2
5	Wasting	2	90	30	120	360	25	9	2/3
6	Minor	1D6–2	3	5	5	5	17+1D6	None	0/1
7	Respiratory	5	5	5	9	7	21	1	0/1
8	Minor	1D6–2	5	3	2	2	15+1D6	None	0/0
9	Respiratory	6	3	7	21	42	24	1	2/3
10	Skin	4	1	5	10	14	20	8	2/2
11	Heart	5	7	3	2	120	20	9	3/3
12	Killer	6	3	3	7	100	20	10	2/2

comparing it to the target number (2xCON). If the roll is failed, the individual is infected.

Incubation: A disease will usually take a number of days after the patient is exposed before symptoms appear. During this time the patient is infectious and may spread the disease to others.

Diagnosis: Characters with Medical skill may attempt a diagnosis task. If the task fails, the wrong disease will be diagnosed, and the prescribed treatment may be ineffective. Each disease has a task level indicated in its description. This is for diagnosis during Phase I. Diagnosis during Phase II is one level easier because the symptoms are more advanced.

Recovery: The patient recovers if he rolls the recovery number or greater on 1D10 modified by adding the treatment received (+n), the Medical *skill level* of the person administering the treatment, and the CON of the diseased character. Negative modifiers should be assigned for inadequate diet (–1) and inadequate shelter (–1) as described on TNE page 199. A recovery roll is made at the end of Phase I. If the roll fails, make a second roll at the end of Phase II. If treatment is not begun until Phase II (or there is no treatment at all), only the Phase II roll is attempted, and any treatment DMs are halved. If the Phase II roll fails, roll 1D10 against the Death Number. A roll equal to or less than the number means the patient has died. If the patient lives after rolling the Death Number, he suffers a permanently reduced fatigue level equal to the Non-Treated fatigue level for that disease.

Duration: The disease is active during Phases I and II, and the patient will not begin to recover until the end of Phase II, no matter when the successful recovery roll is made. The patient may find his fatigue level increased during the Recovery period. There are two Recovery Fatigue levels for each disease in the table. Apply the first to the patient if he was successfully treated in during Phase I. Apply the second if he was treated during Phase II or was not treated at all.

Disease Types: Because thousands of diseases can be found on each planet, it is more useful to describe them by type than individually. Some are minor, mere annoyances. Others are swiftly lethal. Where DMs are prided for multiple drug types (i.e., metabolic, antitoxin, and antibiotic, see TNE page 335), use only the single DM for the drug used. Some of these diseases may be already known, with appropriate antitoxins and antibiotics already available, but some may be unknown, and require research and fabrication of new cures (referee's discretion).

Crippling: This attacks the nervous system controlling the extremities. It paralyzes the patient, sometimes causing him to draw up his limbs in a grotesque rictus. Advanced stages of this disease can kill by paralyzing the diaphragm and preventing breathing. Similar Terran disease: polio. Diagnosis is Formidable.

Treatment: Metabolic (+6), administer oxygen (+1), relieve pain and fever (+1).

Intestinal: This causes severe cramps, diarrhea, nausea, vomiting, and severe dehydration. Similar Terran disease: cholera. Diagnosis is Difficult.

Treatment: Metabolic (+6), specific anti-toxin (+6), antibiotic (+2), intravenous fluids (+2), relieve pain and fever (+2).

Nerve: This attacks the brain and central nervous system. Paralysis and death may result. Similar Terran disease: encephalitis. Diagnosis is Difficult.

Treatment: Metabolic (+6), specific anti-toxin (+6), antibiotic (+4), relieve symptoms (+1).

Wasting: This is a long term disease that gradually debilitates the patient over time. The patient suffers drastic loss of weight, muscle mass, and strength. Similar Terran disease: some forms of cancer. Diagnosis is Formidable.

Treatment: Metabolic (+4), surgery (surgeon's skill).

Minor: This represents a minor respiratory and/or intestinal infection. Similar Terran disease: cold or flu. Effects differ slightly to represent differences in severity. Diagnosis is Difficult.

Treatment: Antiobiotics/metabolics (+8), relieve pain and fever (+2).

Respiratory: This disease attacks the lungs and interferes with breathing, as well as being generally debilitating. Similar Terran disease: pneumonia. Effects differ slightly to represent differences in severity. Diagnosis is Difficult.

Treatment: Metabolic (+6), antibiotics (+4), relieve pain and fever (+2).

Skin: This is a skin infection accompanied by fever. Caused by a fungus, this disease can attack the mucus membranes of the mouth, nasal passages, and eventually the lungs where it can cause death by suffocation. Similar Terran disease: severe and massive thrush fungal infection. Diagnosis is Formidable.

Treatment: Metabolic (+4), relieve symptoms (+2).

Heart: A viral infection that attacks the heart muscle. This disease has a high mortality rate. If the patient does not die, he is severely debilitated. Similar Terran disease: scarlet fever. Diagnosis is Difficult.

Treatment: Metabolic (+2), relieve symptoms (+2).

Killer: This is a massive, general viral infection of the blood and all the body's vital organs. Patients mostly die within two weeks. Similar Terran disease: Streptococcus infection, but much more deadly and untreatable. Diagnosis is Formidable.

Treatment: Metabolic (+2), relieve symptoms (+1).

CHAPTER 4: COLONIAL ECONOMICS & INFRASTRUCTURE

RUNNING A COLONY

In order to run a high-level world tamers campaign, the PC colony (or bootstrap team) leaders need to be able to make decisions that have an impact on the growth and success of the colony, and also need to understand the functioning of the colony so that these decisions can be made in an informed and rational manner. This requires a simple and effective model of the economic processes that go on in a colony.

This model is presented below for use with the Bootstrap and Colony adventures presented in this book (Chapters 6 and 7). It can also be used as the basic system for an infinite variety of other **Traveller** situations, such as working out the details an existing colony, outpost, or primitive society encountered in the Wilds. As a simple system, it is amenable to add-on modifications for additional color or variation, and referees should feel free to experiment with it to allow for variations in local conditions.

THE COLONIAL ECONOMIC MODEL

The economy of a colony is divided into four general sectors: agriculture, industrial production, materials, and power.

Agriculture is the organized production of foodstuffs to feed the colonists or export for cash. This includes crop farming, animal husbandry, and fishing.

Materials is the extraction of raw materials from the environment for use in the other three economic areas. It includes mining of minerals and solid fuels from the ground, wells to extract petroleum, logging, and even the raising of certain non-food crops such as cotton and hemp.

Manufacturing is the conversion of raw materials to finished manufactured items. It is divided into heavy industry, light industry, and construction. Heavy industry produces large vehicles and machinery, as well as smelting metal from ore. It is necessary for industrial expansion. Light industry makes finished consumer goods, such as furniture, electronics, and textiles. Construction builds infrastructure items such as roads and housing.

Power generates electrical power (or its equivalent at earlier tech levels) for industry.

Basic Structure

Each of the four economic sectors is defined within the same set of categories (the energy sector is an exception in some of the areas, see the Energy section below for details): labor, capital, energy, raw materials, required land, and output, as defined below.

Labor: This represents the number of people working in that sector of the economy. The unit used to quantify the amount of labor is the *laborer*. The greater the number of laborers working in a sector, the greater the output that sector can create. In the model, however, a laborer is defined as the actual workers in an area as well as their dependants. This avoids the need to keep separate track of total population as opposed to actual labor force. Thus a family of four in the agricultural sector would count as four laborers.

Capital: This represents the quantity of equipment, tools, and machinery that is devoted to this sector of the economy. For agriculture this is plows, barns, fishing boats, etc., for industry it is factories, for materials it is mines, digging equipment, oil wells, and the like. For simplicity, this capital equipment is quantified not in numbers of pieces of machinery, but by its value in *credits*. This allows rough equivalencies to be made between such dissimilar things as shovels, fish traps, and rivet guns.

The greater the amount of capital in a sector, the more labor-saving devices are available, which increase the productivity of the labor in the sector, increasing the output of that sector.

For you budding Marxists out there, "capital" in this sense is equivalent to *the means of production.*

Land: Both agriculture and raw materials production require land, and that requirement is measured in square kilometers per laborer. The requirements for agriculture vary with tech level. The requirements for materials vary with the richness of the deposit. Poorer deposits require larger tracts of land to extract economically useful amounts of materials. The richness of deposits is determined by the planetary survey (see page 21). Each 20-kilometer mapping hex has an area of 350 square kilometers.

Power: Power is required by certain sectors to operate their equipment. In most cases, this power can be assumed to be electrical in nature (although at low tech levels it might be mechanical energy transmitted short distances by gears and pulleys, etc.). Power is measured in *Kilowatts*, where 1000 Kilowatts equal 1 Megawatt (multiply power in Kilowatts by 0.001 to get Megawatts).

Raw Materials: Sectors require raw materials to operate their machinery (in the form of fossil fuels) or to transform into manufactured goods (iron to make steel, steel to make machinery, cotton to make clothing, copper to make electrical wiring, etc.). Raw materials are measured by their mass in *tonnes*.

Output: Output is the end product produced by the economic sector in question. The units in which output is measured depends upon the sector, as the industrial sector produces capital, the materials sector produces raw materials, the energy sector produces power, and the agricultural sector produces the food eaten by all citizens.

Agriculture

Agricultural output is a product of labor, capital, land, and (at higher tech levels) raw materials. All must be present to produce food. The basic building block is labor.

Labor: The basic unit of measure is the Agricultural Laborer. Agricultural Laborers (ALs) comprise all of the agricultural members of the population (farmers, their families, etc.). In order to produce agricultural output, each AL requires capital, land, and raw materials. This varies by tech level as explained below.

Capital: Capital goods are the machines that labor operates to farm the land (plows, tractors, combines), as well as necessary buildings (such as grain silos, barns, and farrowing houses) and livestock. Normally each AL is provided with one unit of agricultural capital goods. The price of a unit of agricultural capital goods is listed on the table below.

Excess Labor: Societies short of capital may still increase agricultural production by employing more agricultural workers. Up to twice as many ALs of labor may be employed in the agricultural sector as there are units of capital, but all ALs in excess of the total units of capital produce at half the normal rate. For simplicity, where labor exceeds capital, subtract the units of agricultural capital from the total number of agricultural laborers. Multiply the result by 0.5, and add this number to the number of units of agricultural capital.

The result is the output multiplier which is applied to the agricultural sector's output (see below). Results of greater than 1.5 times the total units of agricultural capital are not possible.

AC + (0.5×[AL–AC]) = Output Multipler
with a maximum result of 1.5×AC
AC: units of agricultural capital
AL: agricultural laborers

What is a Laborer?

In the passages below, economic relationships are defined in terms of *laborers*: agricultural laborers (AL), industrial laborers (IL), and material laborers (ML). These are treated as abstract units for the purposes of computing the functioning of the colonial economy, but they have real-world equivalents.

Each laborer is equal to one actual person in the colony's population. This individual person is not necessarily a member of the workforce, however. Each laborer represents roughly one quarter of a worker, representing the members of a society who are too young or too old to work, or are otherwise occupied in non-workforce roles (including full-time parents, etc.). Thus if a colony currently has 800 industrial laborers, this number includes the families of the actual industrial workers, whose actual number is around 200.

This distinction does not affect the way the economic model works, but is helpful to referees and players attempting to visualize the roleplaying "reality" that is being modelled here.

Excess Capital: Societies short of labor may increase production by using more and better machines (capital goods). Each AL which has a second unit of capital assigned to it produces at 1.25 times the normal rate. An AL derives no additional benefit from having more than two units of capital assigned to it. For simplicity, where capital exceeds labor, subtract units of labor from units of capital. Multiply the result by 0.25 and add this to the total units of labor.

The result is the output multiplier which is applied to the agricultural sector's output (see below). Results greater than 1.25 times the total AL are not possible.

(0.25×[AC–AL])+AL = Output Multiplier
with a maximum result of 1.25×AL
AC: units of agricultural capital
AL: agricultural laborers

Livestock: An additional component of agricultural capital is livestock. Livestock is measured in terms of rations (as they are edible, and can be replaced from agricultural production by converting slaughter animals to breeding stock). Each AL must be provided with rations equal to the rated monthly output for that tech level as initial livestock, up to a maximum of 33 rations. As with capital goods, this is a one-time investment. Unlike capital goods there is no continuing maintenance cost.

For example, a tech level 7 colony wishes to add additional ALs to the farm work force. Each AL requires Cr4900 in heavy industry output, Cr4900 in construction industry output, and 21 rations worth of livestock. An additional AL in a tech level 11 colony requires Cr12,100 in heavy industry output, Cr12,100 in construction industry output, and 33 rations worth of livestock.

Certain random events may cause the colony to lose livestock, in which case they must be replaced from food reserves or production. ALs which do not have their required livestock capital suffer a 10% reduction in agricultural output.

Buying New Agricultural Capital: Agricultural capital is produced by the heavy industry sector, and the tech level of the new capital is equivalent to the tech level of the industrial capital that manufactured it. Agricultural capital may also be deliberately built at any tech level lower than that of the manufacturing industrial capital.

Land: Each farm laborer requires a fixed amount of land to farm. This amount increases with tech level, and is noted on the table below. Land requirements are based on the number of ALs *or* the units of agricultural capital, *whichever is less*. Extra labor or capital are used to increase output on land already under cultivation, and so do not increase land use.

The survey of the hex in which the colony is located will provide a richness rating of the land as well as a useable percentage. The richness rating is a modifier to agricultural output. The useable percentage is the proportion of the land in the hex (and in each 20-kilometer mapping hex within it) which can be used for farming.

Power: The agricultural sector has no specific needs for power; these are subsumed within other sections of the economic model.

Raw Materials: From tech level 4 and above, the agricultural sector requires an amount of raw materials, measured in tonnes per month, to produce food. This amount of raw materials is based on the number of ALs *or* the units of agricultural capital, *whichever is greater.*

These raw materials include fuel for farm machinery, fertilizers, pesticides, herbicides, etc. If this is not provided, that AL or unit of capital produces food, but only at the rate for tech level 3. When some raw materials are provided, but not enough for the entire sector, the colonial leadership will have to decide how to allocate raw materials to existing units of agricultural capital and assign ALs to the supplied and unsupplied units of capital.

The per-AL energy requirement differs with tech level. Raw materials are only required in months of the growing season (as determined in the Survey chapter).

Output: Output of the agricultural sector is measured in a base value of "rations" produced per month per AL or AC. A ration is enough to feed one person for one month at subsistence level. Agriculture only produces rations during the growing season (as determined in the Survey chapter). The capital provided for each AL is assumed to include sufficient storage space for whatever rations are produced.

This tech level-based value is multiplied by the Output Multiplier calculated above. This output is multiplied by the hex's richness rating as determined by the survey.This output may be further modified by random events and the results of the monthly output roll.

For purposes of transportation, a ration (food for one person for one month) masses 0.1 tonne and displaces 0.1 cubic meter.

AGRICULTURAL SECTOR KEY VALUES

TL	*AC*	*RM*	*Land*	*Output(Rations)*
0	—	—	0.1	2
1	300	—	0.15	3
2	800	—	0.2	4
3	1500	—	0.3	6
4	2400	1	0.4	9

11	24,200	14	1.1	45
12	27,600	16	1.0	52
13	31,200	14	0.8	60
14	35,000	12	0.6	68
15	39,000	10	0.4	75

What is the Tech Level of My Colony?

The tech level of a colony is determined by the tech level of its capital machinery. Since capital machinery is purchased separately for the separate economic sectors, different sectors can be at different tech levels, and a single sector can include capital machinery from more than one tech level.

In general terms, the difference in tech levels between two sectors cannot be greater than one, and a single sector can have capital machinery from only two consecutive tech levels at a time: the lower tech level it is converting from, and the higher tech level it is converting over to.

Since this is a science fiction game in which a virtually infinite variety of social structures can be encountered, referees should feel free to design societies that have greater technological differences between or within sectors, but for the purposes of PC groups leading their own colonies, the one TL limit above should be enforced.

Industrial Production

Industrial production is a product of labor, capital, energy, and raw materials. All four must be present to produce finished goods. For our purposes, the basic building block will be labor.

Labor: The basic unit of measure is the Industrial Laborer. Industrial Laborers (ILs) comprise all of the members of the population associated with the manufacture of finished goods from raw materials. At each tech level the capital, power, and raw material needs of an IL are different, as explained below.

Capital: Capital goods are the machines that labor operates to manufacture finished goods, as well as the buildings that house them. Normally each IL is provided with one unit of industrial capital goods (IC). The price of a unit of industrial capital goods (one IC) is listed on the table below.

Excess Labor: Societies short of capital may still increase industrial production by employing more workers. Up to twice as many ILs of labor may be employed in the industrial sector as there are units of capital, but all ILs in excess of the total units of capital produce at only one-half the normal rate. For simplicity, where labor exceeds capital, subtract the units of industrial capital from the total number of industrial laborers. Multiply the result by 0.5, and add this number to the number of units of industrial capital.

The result is the output multiplier which is applied to the industrial sector's output (see below). Results of greater than 1.5 times the total units of industrial capital are not possible.

IC + (0.5×[IL–IC]) = Output Multiplier
with a maximum result of 1.5×AC
IC units of industrial capital
IL: industrial laborers

Excess Capital: Societies short of labor may increase production by using more and better machines (capital goods). Each IL which has a second unit of capital assigned to it produces at 1.25 times the normal rate. An IL derives no additional benefit from having more than two units of capital assigned to it. For simplicity, where capital exceeds labor, subtract units of labor from units of capital. Multiply the result by 0.25 and add this to the total units of labor.

The result is the output multiplier which is applied to the industrial sector's output (see below). Results greater than 1.25 times the total units of industrial labor are not possible.

(0.25×[IC–IL])+IL = Output Multiplier
with a maximum result of 1.25×IL
IC: units of industrial capital
IL: industrial laborers

Types of Industrial Capital: There are three types of capital goods: heavy industry capital goods, light industry capital goods, and construction industry capital goods. These types differ in terms of capital goods requirements and in what they may manufacture. The price listed on the table below is for light industry capital goods; heavy industry capital goods cost three times this amount, while construction capital goods cost half this amount.

When purchasing capital goods for any sector, half must be produced from heavy industry output and half from construction output. When initially setting up a colony the machinery for industry is usually transported in by starship, but the buildings to house it (the half of the cost represented by the construction sector) must still be erected. (See pre-fabricated buildings on page 36 of the infrastructure section following.)

Buying New Industrial Capital: Existing heavy industrial capital can manufacture new industrial capital at any tech level equal to or less than its own.

Heavy industrial capital may build new industrial capital at the current tech level +1 at *twice* the listed cost, and only if all capital (of all types: agricultural, raw materials, and all three types of industrial) has already been brought up to the same tech level. This means that on the turn immediately following this technological breakthrough, the lower tech industrial capital may no longer build at the current TL +1: all new capital at the higher tech level must be built by the new "prototype" capital. (This artificiality is intended to put the brakes on technological advancement within this simple economic model without having to expand it to include complex rules on research and development, science, etc.)

Converting Industrial Capital: Existing industrial capital may be converted into industrial capital of the next higher tech level at the rate of 20% of its cash value. For example, 100 units of TL-4 light industrial capital are valued at (Cr500×100=) Cr50,000. If this were to be converted to TL-5 light industrial capital, the amount would be 20% of 50,000 or Cr10,000, which would become (10,000÷1350=7.4, dropping fractions =) 7 units of TL-5 light industrial capital. This conversion may only be conducted if at least 50% of the current heavy industrial capital is at this higher tech level, and the new (higher TL) value of the converted equipment must be less than or equal to the current heavy industrial output in credits.

Industrial capital may only be converted into higher-tech industrial capital of the same type, i.e., light industry into light industry only, heavy industry into heavy industry only.

Land: The industrial sector requires no land of its own *per se.* Rather, the land required for industry is factored into that required for housing infrastructure (see the Infrastructure section, below).

Power: Each IL of labor requires a fixed amount of power to produce finished goods. If this is not provided, that IL cannot work (and produces nothing in that period). The per-IL power requirement differs with tech level, and is expressed in terms of kilowatts of power generating capacity continuously devoted to industry.

Raw Materials: Each IL of labor requires a fixed amount of raw materials, measured in mass tonnes per month, to produce finished goods. If this is not provided, that IL cannot work (and produces nothing in that period). The per-IL energy requirement differs with tech level. Heavy industry requires twice the listed mass of raw materials if producing heavy manufactured goods (see Output below). If producing light manufactured goods it requires the listed mass of raw materials.

Output: The base output in finished goods of an IL is measured in Credits of value produced per month. This base value can be

INDUSTRIAL SECTOR KEY VALUES

TL	Light IC	Heavy IC	Construction IC	KW	RM*	Output
0	5	15	2.5	—	0.1	50
1	10	30	5	—	0.2	75
2	15	45	7.5	—	0.3	100
3	150	450	75	0.1	1	200

11	24,000	72,000	12,000	2.0	70	3000
12	28,000	84,000	14,000	2.2	75	3500
13	32,000	96,000	16,000	2.4	80	4000
14	37,000	111,000	18,500	2.6	85	4500
15	42,000	126,000	21,000	2.8	90	5000

*Value listed is for the production of light manufactured or construction goods. For the production of heavy manufactured goods (possible only with heavy capital goods), double this value.

adjusted up or down based upon provision of capital goods (as explained above) and by the results of the monthly output roll.

Heavy Industry may produce either heavy industrial goods or light manufactured goods. Light industry may only produce light industrial goods. Construction industry produces infrastructure.

Heavy industrial goods are the capital goods used in all of the economic sectors, plus power plants, vehicles, aircraft, ships, spacecraft, artillery, large rockets and missiles, etc.

Light industrial goods are all other manufactured items (electronics, home appliances, paper products, pharmaceuticals, textiles, furnishings, military small arms, shoulder-fired rockets and missiles, etc.).

Infrastructure consists of buildings, roads, bridges, starports, monorails, etc.

Materials Industry

The materials sector of the economy produces the raw materials that are used by the other sectors to fuel vehicles, fertilize the ground, and build finished goods (all of which are abstracted into a single raw material requirement) . Materials production is a product of labor, capital, land, and power. It does not require materials, but rather produces them. For our purposes, the basic building block will be labor.

Labor: The basic unit of measure is the Materials Laborer. Materials Laborers (MLs) comprise all of the members of the population associated with discovery, collecting, creation, and/or extraction of raw materials. At each tech level the capital and energy needs of an ML are different, as explained below.

Capital: Capital goods are the equipment that labor operates to find and recover or produce raw materials, as well as the structures in which these operations are conducted. Normally each ML is provided with one unit of capital goods. The price of a unit of capital goods is listed on the table below.

Excess Labor: Societies short of capital may still increase raw materials production by employing more workers. Up to twice as many MLs of labor may be employed in the materials sector as there are units of capital, but all ML in excess of the total units of capital produce at only one-half the normal rate. For simplicity, where labor exceeds capital, subtract the units of materials capital from the total number of materials laborers. Multiply the result by 0.5, and add this number to the number of units of materials capital.

The result is the output multiplier which is applied to the materials sector's output (see below). Results of greater than 1.5 times the total units of materials capital are not possible.

MC + (0.5×[ML–MC]) = Output Multiplier
with a maximum result of 1.5×MC
MC: units of materials capital
ML: materials laborers

Excess Capital: Societies short of labor may increase materials production by using more and better machines (capital goods). Each ML which has a second unit of capital assigned to it produces at 1.25 times the normal rate. An ML derives no additional benefit from having more than two units of capital assigned to it. For simplicity, where capital exceeds labor, subtract units of labor from units of capital. Multiply the result by 0.25 and add this to the total units of labor.

The result is the output multiplier which is applied to the materials sector's output (see below). Results greater than 1.25 times the total units of materials labor are not possible.

(0.25×[MC–ML])+ML = Output Multiplier
with a maximum result of 1.25×ML
MC: units of materials capital
ML: materials laborers

Buying New Materials Capital: Materials capital is produced by the heavy industry sector, and the tech level of the new capital is equivalent to the tech level of the industrial capital that manufactured it. Materials capital may also be deliberately built at any tech level lower than that of the manufacturing industrial capital.

Land: The materials sector requires land to extract and process raw materials. Land requirements are determined by the planetary survey. Each hex will have a richness rating and a useable percentage rating. The richness rating is the tonnes of raw material per month which can be extracted from a square kilometer of land. The useable percentage is the percentage of land in the hex which may be used to extract raw materials. It is possible to have a high richness rating and a low useable percentage, indicating a limited but very concentrated deposit.

Land use per ML is based on the output of those MLs. For example, 10 TL-6 MLs properly supplied with capital and power can produce 1500 tonnes of raw materials per month. The amount of ground required to support this output varies with the richness rating. If the materials richness rating of the hex were 100, the 10 laborers would require 15 square kilometers to meet their capabilities.

Power: Each ML of labor requires a fixed amount of power to produce raw materials goods. If this is not provided, that ML can work but only produces output at the TL-2 level. The per-ML power requirement differs with tech level, and is expressed in terms of kilowatts of power generating capacity continuously devoted to the materials sector.

Output: The base output of the materials sector is in tonnes of raw materials per month. This base value can be adjusted up or down based upon provision of capital goods (as explained above) and by the results of the monthly output roll.

Materials Sector Key Values

TL	*MC*	*KW*	*Output*
0	0.5	—	1
1	1	—	2
2	1.5	—	3
3	15	0.1	10
4	50	0.2	40
5	135	0.3	70
6	300	0.4	150
7	650	0.8	300
8	1100	1.2	450
9	1500	1.5	550
10	2000	1.8	650
11	2400	2.0	700
12	2800	2.2	750
13	3200	2.4	800
14	3700	2.6	850
15	4200	2.8	900

Agricultural Production of Raw Materials: Agricultural products can be used for textiles, fuel, building materials, synthetics, glues, and a host of other raw material functions. If desired, up to 30% of the colony's raw materials needs may be met by agricultural produce. Each ration masses 0.1 tonne and may be used on a one-for-one basis for raw material. Thus ten rations could be substituted for one tonne of raw materials.

Power

This segment of the economic model produces the power that is consumed by the other sectors of the economy. The power sector does not require persons to be assigned to it, only to have the proper power-generating equipment built, and to have materials (fuel) and

maintenance provided for it. There are no "power laborers."

Power-generating equipment is designed using the Power Production sequences in **Fire, Fusion, & Steel**, and/or the supplemental power generation systems detailed below.

Chemical Power: Any of the chemical power production plants listed in **Fire, Fusion, & Steel** can be used as a stationary power source.

The fuel demand in tonnes of a chemical power plant must be calculated so that these needs may be met by the materials sector of the economy and the transportation network.

Because the economic model does not distinguish between fossil fuels, it is only important that these are noted as being present on the planet. However, to simulate the use of coal instead of oil or natural gas at lower tech levels, use the coal fuel use multiplier from **FF&S** (×1.5) at TLs 3 and 4. If fossil fuel is not available on the world, chemical power plants must instead burn alcohol or wood at the conversion rates listed in **FF&S**. However, aside from the differences in required tonnages, these different types of fuel are all supplied by the materials sector without differentiation.

Nuclear Power: These are designed using the Nuclear Power Plants table of **FF&S**. Fission power plants must have a supply of radioactives, either from local sources or from off-planet. In the case of high-tech fission plants that are maintained from off-world, it is assumed that this off-world maintenance includes refueling, so a local supply of radioactives is unnecessary.

Hydro Power: In the survey chapter, each planetary hex was evaluated for the total quantity of extractable hydro power. This power is extracted using the water wheels and turbines on the table below. At TL 4 and lower, this power is hydromechanical, and is extracted via gears and pulleys to operate machinery. At TL 5+, electrical generator turbines extract this power as hydroelectric power which is naturally much more flexible in the uses it can be put to, although this economic infrastructure model imposes no penalties on the use of low tech hydromechanical power.

Water wheels and hydrogenerator turbines at a given tech level have a listed efficiency of extraction. This shows the limit to the amount of extractable hydro power in the hex that can actually be harnessed at that tech level. Multiply the hex's extractable hydro power by this number to find this maximum quantity of power at each tech level.

The extraction of a mapping hex's hydro power via hydrogenerators removes a portion of that hex's land area from other service, i.e., it cannot be also used for housing, agricultural, or raw materials land. This simulates the large reservoirs created by hydroelectric projects. Divide the power output of installed hydrogenerators by the total extractable hydro power in the hex (modified by the TL extraction efficiency) and divide by 2. The result is the percentage of area in the hex that can no longer be used for any other purpose. These penalties to not apply to water wheels, which are simply placed alongside streams or rivers, requiring their attached facilities to also be close by.

Hydrogenerators may not be imported from off world; they may only be manufactured by the construction sector of the world. This is because TL-5+ hydroelectric projects require massive and time consuming programs to build dams, and this capacity is limited by local productive capacities and cannot be simply bought and installed.

Water wheels may be imported. Both water wheels and hydrogenerators are treated as being constructed by the economy's construction sector.

HYDRO POWER GENERATORS

TL	*Type*	*MCr per kW output*	*Efficiency*
1	Water Wheels	0.01	0.4
3	Water Wheels	0.02	0.5
5	Hydrogenerators	0.25	0.95

Wind Power: In the survey chapter, each planetary hex was evaluated for the total quantity of extractable wind power. As with hydro power above, wind generators have extraction efficiencies that vary with tech level. Multiply the hex's extractable wind power by this number to find this maximum quantity at each tech level.

Also like hydro power, harnessing a hex's wind power removes portions of that hex's land area from service. Multiply the hex's extractable wind energy by the tech level efficiency figure on the table below. Then take the total installed output of wind generators installed in the hex and divide it by the modified extractable energy available in the hex. The result is the percentage of square kilometers in the hex that are no longer available for any other use because they are now covered by wind turbine farms.

WIND POWER GENERATORS

TL	*Type*	*MCr per kW output*	*Efficiency*
3	Windmills	0.01	0.3
4	Windmills	0.05	0.5
5	Wind Turbines	0.2	0.8
7	Wind Turbines	0.25	1.0
9	Wind Turbines	0.3	1.2
12	Wind Turbines	0.4	1.5

Solar Power: Solar power arrays described in **FF&S** may be assembled in ground installations to provide supplementary power during daylight hours. However, unless sufficient storage batteries are available, a solar array can provide no power at night.

Orbiting solar arrays capable of capturing stellar energy from synchronous orbit and beaming it to surface rectifier/antenna (rectenna) installations can overcome most of the daylight limitation. These solar arrays transmit their power to the ground rectennas via large masers. Double the price and mass of the solar cells (not collector panels) to allow for the transmission masers and capacitors/batteries required to hold the power during transmission interruptions.

Rectenna installations are needed to receive the microwave power and to step down the frequency to a standard electrical range (50-60 hertz). The rectenna installation area is 100 square meters per megawatt of power being beamed down from orbit. Rectenna installations cost MCr0.1 per 100 square meters.

Infrastructure

A colony requires a certain basic level of physical infrastructure, consisting of transportation and housing. Both of these are built by the construction sector, while vehicles to move goods on the transportation lines are built by heavy industry.

Transportation: Cities require transportation lines into them from farm communities to move food, and from resource sites to bring raw materials. In addition, each inhabited 20-km hex requires a road network within it for local traffic. In both cases (resource transportation roads and local transport nets) are based on population, although the presence of heavy industry in a city will increase this.

For purposes of this model, the term *city* and *colony* are functionally equivalent terms, denoting a self-supporting population. While larger (hence older) cities/colonies may be spread over multiple hexes, bringing agricultural goods and raw materials from outlying hexes into the central industrial hex, young colonies will likely have all of their economic components—agricultural, materials resource sites, and industrial—located within the same 20-km hex.

All of these described transportation lines include roads and rail transportation (as appropriate to tech level, of course), but as any net includes elements of both of these types, they are abstracted as a general transportation capability. Transportation lines are rated by their potential load value, in millions of tonnes per month. A TL-1

transportation line has a load value of 0.5 million tonnes per month, for example, while a tech level-5 line has a load value of 8 million tonnes, and a tech level-8 line has a load value of 30 million tonnes. None of the transport nets or lines below are considered to take up any of the space in a hex, but are subsumed within the other land usages.

Local Transport Net: Each inhabited 20-kilometer hex of the colony requires 500 kilometers of road for local traffic. The population that can be accommodated in each hex is equal to the road net's load level in tonnes. As each 20-km hex may only have the single 500-kilometer road net built within it, this creates a tech level-based restriction on the maximum population that can live in a hex. As an economy's tech level increases, it is possible to upgrade the local transport net (by simply building a new 500-kilometer net which is assumed to replace the old one) to allow more people to live in the hex.

Resource Transport Lines: Resource transportation lines are required in inhabited hexes in addition to the transport net described above. Resource transportation lines consist of 20-kilometer stretches of roads, i.e., transportation arteries running from one side of the hex to the other. The required load level of the resource transportation system supplying a hex is equal to the tonnes of raw materials required per month plus the hex's total population multiplied by 0.1. Several such arteries may be built to meet the required load level. Thus a TL-2 colony hex with a required load level of 4 million tonnes would have to have at least four such 20-kilometer roads (4×the load level of 1 million tonnes per road = 4 million tonnes), at a total cost of (80km×MCr0.0015=) Cr120,000.

If raw materials or rations are drawn from sites outside the hex containing the city, those hexes must be linked to the hex containing the city hex by transportation lines of sufficient load level to carry the raw materials or food. Each such transportation line leading into the city must equal or exceed the required load level or the city will not receive sufficient food or raw materials.

For example, a city hex is inhabited by 30,000 persons and draws in a total of 6,000,000 tonnes of raw materials and food each month. Of that tonnage, 2,000,000 is produced within the hex itself, 1,000,000 is produced in a hex two hexes from the city, and 3,000,000 is produced in a hex three hexes away from the city. Each of the three occupied hexes requires its own 500-km local road net. Although the colony's tech level is 2, the local nets are left at TL-0,

ROADS

Roads are basic to any society. The first roads are dirt tracks through the wilderness, and the first streets are the spaces between the buildings in a village. As a society advances and finds and utilizes sources of petrochemicals, limestone, sand, and gravel, roads are paved so that wheeled traffic can move more efficiently, mud can no longer bog down vehicles, and dust and dirt generated by passing traffic is kept to a minimum.

Roads allow vehicles to move from point to point at speeds greater than their normal cross-country speeds by levelling out uneven terrain, eliminating mud, etc. The low-tech roads described below provide a road bonus which is added to the vehicle's cross-country speed while travelling on the road. However, this speed cannot exceed the vehicle's permanent rated road speed (as calculated in the design sequence or listed with the vehicle's ratings). At higher tech levels, roads simply allow vehicles to use their rated road speeds.

Trails & Tracks (TL 0): These are the first overland roads. They cost nothing to build as they are essentially formed by the passage of humans and their wagons and sometimes by the passage of local animal life. Vehicles using trails and tracks move at their cross-country speed rate +1.25 kph (add 5 to cross-country travel move) as they do not have to break through brush. They are reduced to their basic cross-country speed in rainy weather because of mud.

Improved Trails & Tracks (TL 1): These are basically trails and tracks that have been widened and graded with animal-powered scrapers. Traffic may pass in opposite directions without one party leaving the road. Vehicles using improved trails and tracks move at their cross-country speed rate +2.5 kph (add 10 to cross-country travel move) in good weather, but are reduced to their cross-country speed in rainy weather because of mud.

Crowned Roads (TL 2): These roads are constructed with a cambered surface so that water will flow off them to be carried away by drainage ditches alongside them, and are usually also topped with gravel or stones. Vehicles using crowned roads move at their cross-country speed rate +3.75 kph (add 15 to cross-country travel move) and do not have a mud penalty in rainy weather.

However, continuous use by heavy vehicles (10 tonnes or greater) will destroy these roads in 1D20 days, and sustained use by tracked vehicles will destroy them after only two hours, in either case reducing them to the quality of improved trails and tracks, above.

Macadam Roads (TL 3): These are crowned and drained roads surfaced with chipped stones or gravel to form a water-impervious surface. Vehicles moving on macadam roads move at their cross-country speed +5 kph (add 20 to cross-country travel move) and do not have a mud penalty in rainy weather.

Sustained use of the road by heavy vehicles (10 tonnes or greater) will destroy these roads in 1D10 weeks, and use by tracked vehicles will destroy the surface in six hours, reducing the road to the quality of an improved trail/track.

Asphalt Roads (TL 4): These crowned and drained roads are topped with a bitumen-gravel mix, and are the basic road type found on mid-technology worlds. They are built with two or more lanes to allow opposing traffic and passing. Vehicles moving on asphalt roads move at their full road speed and do not have a mud penalty in rainy weather.

However, sustained use by heavy vehicles (10 tonnes or greater) will destroy these roads in 10+1D10 months, and use by tracked vehicles will destroy the road surface in 12 hours, reducing the road to the quality of an improved trail/track.

Concrete Roads (TL 5+): A more durable alternative to asphalt roads, concrete roads are surfaced with a mixture of sand, gravel, and limestone which has been thermally converted into cement. Vehicles moving on concrete roads move at their full road speed and do not have a mud penalty.

Concrete roads are not damaged by vehicles of less than 50 tonnes, but will have their surfaces destroyed by 18 hours of sustained use by tracked vehicles, which reduces the road to the quality of an improved trail/track.

Fused Roads(TL 12+): The ultimate in road surfacing and construction, fused roads are built with mobile fusion reactors that use plasma jets to melt and fuse the ground into a thick, ceramic-like surface. Vehicles on fused roads travel at their full road speed. Fused roads are not damaged by heavy nor tracked vehicles, though tracked vehicles usually must be fitted with rubberized track shoes to get proper traction on the ceramic surface.

as the load level at TL 0 still allows up to 100,000 persons to live in a single hex, and is therefore sufficient for the colony's current needs.

The city hex requires resource transport lines with a total load of 6,000,000 tonnes,

Local and transportation lines are built by the construction sector of the economy. The table below lists the load capacity of a single transport line or network (in millions of tonnes), and the cost per kilometer of transport line, broken down by tech level.

TL	*Load*	*MCr*
0	0.1	Free/0.0005*
1	0.5	0.001
2	1	0.0015
3	4	0.003
4	6	0.004
5	8	0.005
6	10	0.006
7	15	0.008
8	30	0.01

*The cost for a TL-0 500-km local road network is free, but resource transport lines cost MCr0.0005 per kilometer.

Required Raw Materials: When calculating required loads above, it is important to remember that the raw materials required by the colony are not limited to those needed by the agricultural, industrial, and power sectors to keep their production going. This number also must include any excess raw material production that is being devoted to off-world trade, as well as the raw material requirements of the armed forces (see below).

Vehicles: In order for a transportation line to operate at its capacity, it must also have transport machinery: cars and trucks for the roads, trains and train cars for the railroads and monorails. These are built by the heavy industry sector, and are measured in units of one million kilometer-tonnes of haulage.

If, for example, a city needed 1,000,000 tonnes of food and raw materials per month, and had to haul it in from a mean distance of four hexes or 80 kilometers (determined by the location of farming communities with sufficient excess food production to feed the city and material sites sufficient to meet its raw material needs), the city would need transport nets with a combined capacity of at least 1,000,000 tonnes (one tech level 2 transport line would be sufficient) and 80,000,000 kilometer-tonnes of vehicles in operation, or 80 units.

Note that vehicles have a raw material tonnage (fuel) for operating, also rated per unit of million kilometer-tonnes. At low tech levels this cost is in rations per month needed to feed the draft animals. This raw material or ration cost is added to the needs of the city being serviced. Thus in the example above, the TL-2 city requires 80 units of transport, and these units require (80×2000=) 160,000 rations per month.

The table below shows the price of vehicles in MCr per million kilometer-tonnes of capacity, as well as the tonnes of raw materials (or, at low TLs, number of rations) required for each million km-tonne unit of vehicles. When purchasing units of vehicles for a colony, note that the maximum tech level of vehicle which may be operated on a local road network or transport line is the tech level of the transport network or line +1. When a road network consists of multiple tech levels, use the lowest tech level present.

The MR column indicates the movement rate of a unit of transportation purchased at that tech level. This value is used only with the armed forces infrastructure below and the mass combat system, pages 46-47.

VEHICLES

TL	*MCr*	*RM*	*MR*
0	2.5	—	2/1
1	1.25	(3300 rations)	3/2
2	1	(2000 rations)	3/2
3	0.5	500	3/2
4	0.4	250	4/2
5	0.3	175	5/2
6	0.2	100	15/5
7	0.175	80	15/5
8	0.15	70	15/5

Housing: Housing is defined in total cubic meters of housing available to the people of the colony. Housing is built by the construction industry and costs Cr100 per cubic meter.

Dividing the total cubic meters of housing by the total population will yield the cubic meters available per person, which is used to determine the Standard of Shelter (see below). As a general rule, 25 cubic meters per person is minimal shelter, usually provided by communal dormitories. Standard of shelter improves up to about 100 cubic meters per person, which is comfortable housing. Additional cubic meters provide more luxury than utility, and progressively greater increases are necessary to obtain meaningful benefits.

Power: Housing does not require power *per se*, as these requirements are subsumed within the per-laborer power requirements for the industrial and raw materials sectors.

Land: Housing requires land, and the amount of land required per cubic meter depends on the tech level. (At higher tech levels, high-rise buildings consume less land area for the cubic meters of housing provided.) The following chart indicates the square kilometers of land required per million cubic meters of shelter at different tech levels. When colony leaders lay out their colony within a hex, they may specify that housing is placed on land not suitable for agriculture or raw materials usage, within the referee's discretion.

TL	*km² per million m³*	*persons per km², assuming 25m³ each*
0	4	10,000
1	2	20,000
2	1	40,000
3	0.8	50,000
4	0.6	66,666
5	0.5	80,000
6	0.4	100,000
7	0.3	133,333
8	0.25	160,000
10	0.2	200,000
12	0.15	266,666
14	0.1	400,000
15	0.05	800,000

Armed Forces

There is one final segment of society that must be considered, and that is the armed forces. These are not included in the economic model above, because their contribution cannot be measured in economic terms. In fact, to the casual observer, the provision of armed forces appears to be a drain upon a society's economy.

It is difficult to measure the marginal value of the common defense, or to determine what is the cheapest amount that can be spent to prevent the destruction of a society by its neighbors. There is substantial agreement among healthy societies that they do wish to be defended, but little consensus on how much defense is enough.

Labor: The armed forces are measured in armed forces laborers.

Armed Forces Laborers (AFLs) represent the portion of society dedicated to military pursuits. The total number of AFLs multiplied by 0.25 yields the number of *troops*, each of which represents one person enlisted in the armed forces.

Capital: Capital goods are the baseline equipment that allow the armed forces to exist: infrastructure such as barracks, armories, typewriters, etc. This value is listed on the table on page 35, and one unit of capital goods must be provided per AFL (not troop). Note that this value does not include weapons of any kind.

All weapons, including small arms, ammunition, vehicles, aircraft, spacecraft, etc., must be purchased or designed and purchased using such resources as the equipment section in the **TNE** basic rules, **Fire, Fusion, & Steel**, the **Reformation Coalition Equipment Guide**, and the equipment section and supplementary design sequences (for black powder and bow weapons) that appear in Chapters 10 and 9 of this book, respectively. The amount of such weaponry purchased depends upon the number of troops available, but the organization of these troops and the level of their equippage is up to the society's leaders (in this case, usually the PCs). See also the Infrastructure subheading below.

Energy: Each troop requires a fixed amount of energy to remain in readiness. If this is not provided, those troops are incapable of responding adequately to hostile acts (referee's discretion). The per-troop energy requirement differs with tech level, and is expressed in terms of kilowatts of power generating capacity continuously devoted to the armed forces.

Raw Materials: The armed forces require raw materials based on the fuel consumption of their capital goods (vehicles, etc.). This is calculated based on the performance data found in the various equipment listings, and is based on the amount of operation that the equipment will undergo in a given month. Note that the amount of raw materials provided will not only govern the tempo of military operations in a war (see page 47 of Chapter 5, the Mass Combat System), but will affect the quantity of training that can be conducted with this equipment in peacetime.

Raw materials should be provided to allow equipment to be operated for a certain number of hours per month. For simplicity, assume that all pieces of military equipment are operated for the same amount of time each month. Equipment designed with **Fire, Fusion, & Steel** or picked from published equipment lists have their fuel consumption rates listed, usually in terms of liters of fuel per hour.

Although goods from the materials sector are referred to as raw materials (which is to distinguish them from the finished goods which come from the industrial sector), for the purposes of this model, assume that these raw materials are fully useable in their delivered form (refined fuel, gasoline, jet fuel, etc.).

Not all fuels are available at all tech levels, which clearly places a limit on the armed forces which can be maintained by a given world. A world whose materials sector tech level (defined as the tech level of capital goods which constitute 50% or more of the materials sector) cannot produce the required fuel type must import fuel for its armed forces.

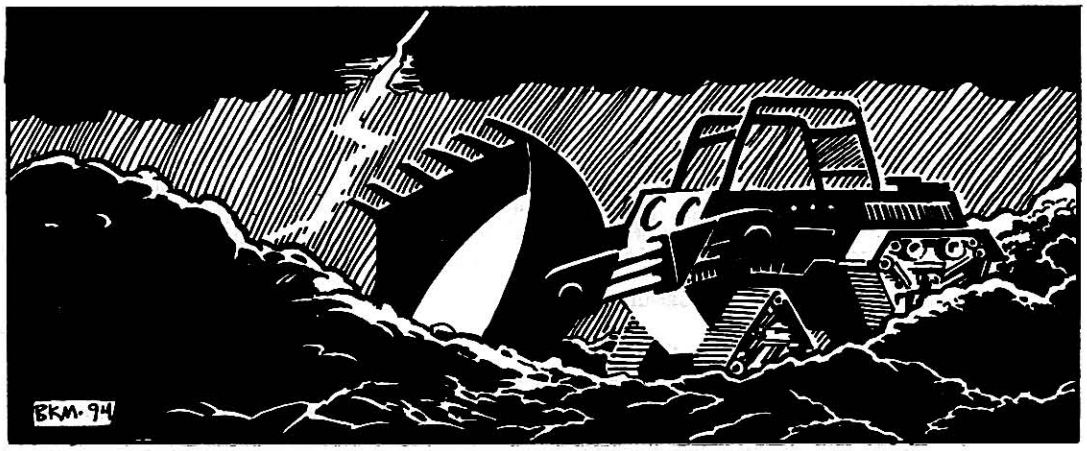
TL	*Fuel Type*	*FC*	*Tonnes per liter*
0	Wood	Bio	0.002
1	Alcohol	Bio	0.001
1	Coal	FF	0.002
4	Hydrocarbon Distillates	FF	0.001
5	Liquid Rocket Fuel	FF	0.001
6	Radioactives	—	0.019
7	High-Grade Hydrocarbon Distillates	FF	0.001
7	Hydrogen Rocket Fuel	—	0.0003
7	Liquid Hydrogen	—	0.00007

FC: Fuel Class. This indicates certain restrictions on fuel availability that vary from world to world, as established in the Survey Chapter. Fuels labelled "FF" (fossil fuels) may only be produced by the materials sector on worlds where such fuels are available. Fuels labelled "Bio" are biological in origin, and may only be produced by the materials sector on worlds where life is possible. The notation "—" indicates no such restrictions.

Note that for armed forces which use animal transportation, each horse (or horse equivalent if using non-Terran beasts) requires one ration and provides an absolute value of 160 hours of operation per month. This 160-hour figure is effectively a minimum usage level, as horses cannot be multi-tasked. For example, if an army's organization requires 100 horses (say, 40 horse-mounted cavalry and 30 wagons each with two horses), it must be provided with 100 rations and is capable of being operated up to 160 hours per month, regardless of whether it actually is. That force could not be provided with only 50 rations and operated at 80 hours per month. On the other hand, if the leaders wished for this army to be able to operate at 240 hours per month, it would require more horses and rations: 150 horses consuming 150 rations per month.

Readiness: The amount of operating hours will affect the readiness of the armed forces by dictating the amount of training that can be conducted.

Quality	*Hours/month*
Elite	120
Veteran	80
Experienced	40
Novice	20



The above activity levels are required to *maintain* the listed troop qualities; units of lower troop quality may not be improved to higher levels by providing them with more hours of operation. For example, a unit of Elite troops must have raw materials provided to it to allow all of its equipment to be operated for 120 hours a month. If it were allocated 80 hours, the unit would fall to Veteran quality, or to Experienced quality if it were allocated raw materials for only 40 hours. A unit whose quality has been allowed to fall for lack of operating hours can be raised back up to its original quality by restoring the appropriate level of raw materials, but each level recovered takes six months. Thus the Elite unit allowed to fall to Experienced quality would require six months of supply at 80 hours before it would be considered to be back up to Veteran quality, and then a further six months of supply at 120 hours before it would be treated as Elite again. (See the **TNE** sourcebook **Path of Tears: The Star Viking Sourcebook**, pp. 95-97 for discussion of how to determine quantity and quality of planetary armed forces.)

Infrastructure: Rather than requiring players to design supply units to support their combat formations, simply total up the mass of ammunition owned by the armed forces plus the mass of the monthly raw materials provided to the armed forces, and purchase transportation sufficient to carry that tonnage of materials from the Vehicles table on page 33 (one unit of vehicles per million tonnes). The table shows the movement rate that will be used for the army's supplies, see page 44 of the Mass Combat Chapter.

Output: The base output of the armed forces is the capability to break things and hurt people, and this is measured using the **TNE** rules for combat (including the rules for mass combat including in Chapter 5). The process of converting that capability into the somewhat intangible commodity called security is the art called *statecraft*. That is the province of the society's leaders. Good luck.

Armed Forces Key Values

Maintenance

Assuming that the average machine tool lasts for about 20 years, every year 5% of the industrial capital (heavy, light, and construction) must be replaced, or 0.4% each month. Half of this is provided by the heavy industry sector and half by the construction industry sector. This is *mostly* what heavy industry does, and if it weren't for this drain on productivity, societies could grow like crazy.

For example, 100 units of tech level 5 heavy industrial capital are worth Cr405,000, and require a maintenance value of (405,000x0.004=) Cr1620 to be paid each month, Cr810 from each of the heavy industry and construction sectors.

When the colony first starts, all of the capital tools and buildings are presumably new, so none need to be replaced. But starting on year 10 of the colony, 0.1% per month must be put into maintenance, 0.2% in year eleven, 0.3% in year twelve, and 0.4% in year thirteen and every year afterwards. (This delayed requirement keeps players from having to worry about this requirement in most cases, which few of them will find disappointing.)

The power sector and armed forces require maintenance at the same rate, based on the monetary value of all installed power generation systems and weapons (but not ammunition).

Infrastructure (including armed forces infrastructure) must be maintained as well, and each month the construction industry must invest 0.2% of the total value of the infrastructure (transportation and housing) in its maintenance.

Agricultural and materials sector capital goods are exempt from maintenance requirements.

If the colony has no heavy industry, or none of sufficient tech level to maintain high-tech imported systems, this maintenance must be imported from off-planet (and is purchased as a simple monetary value). Failure to meet the maintenance requirement leads to a gradual erosion of the capital base, as machines are cannibalized for parts. (That's what's been happening in the Wilds for decades.) The decline in useable capital machinery is *twice* the maintenance shortfall.

Maintenance is paid monthly, based on the quantity of equipment (capital goods, infrastructure, etc.) existing at the beginning of the month.

Weather Effects on Maintenance: Note that the required infrastructure maintenance rate (normally 0.2% per month) may be modified by local weather conditions, as calculated on page 17 of the Survey chapter. If weather factors total +3 or less, there is no change to this base rate. If weather factors total +4 to +5, the monthly rate becomes 0.3%, and if weather factors total +6 or more the monthly rate becomes 0.4%.

Off-World Trade

Trade consists of exports sold off-world to generate money to purchase goods that are imported back to the world. These imports can consist of luxury goods, crucial high-tech spare parts, weapons, capital goods, etc.

A successful economy will produce surplus goods from any or all of the agricultural, industrial, and materials sectors. Even a marginal economy can be controlled to produce trade goods by skimping on the products that are reinvested back into the economy, at the option of that society's leaders.

Exports: First the value of the world's exports must be defined. Industrial production is already defined in terms of credits, but agriculture and raw materials output must be converted into monetary terms.

This is done by converting rations and tonnes of raw materials into displacement tons of starship cargo. For rations, divide by 100 to get displacement tons, and for raw materials divide tonnes by 20 to get displacement tons. Then take the total number of tons of cargo to the top half of page 239 in the **TNE** rulebook and calculate the price that they are purchased for by traders that call at the world. (It is assumed that sufficient starships call each month to purchase all exports that are offered. After all, the Coalition or the sponsoring colonizing world is trying to expand its trade—it would be foolish to not see to it that the opportunities are there.)

Add the price paid for the agricultural and raw materials cargos to the monetary value of industrial exports. This is the total value of the goods in local credits. This value must then be converted using the exchange rates rules found on **TNE** pages 230-231 into terms of the currency of the sponsoring world. (For example, Baldur in the case of the colony adventure. In other cases, such as bootstrap operations, use the friendly base from which the mission was launched.) This is the amount of money available to buy imports.

Imports: Imports may be purchased using the money generated by exports. Note that purchases made with this money must still be adjusted for the exchange rates between the currency's base value and its value on the world where the imports are being purchased. For example, the world sponsoring the colony is a TL 12, Starport B world, and the colony is attempting to purchase goods from a Starport A, TL-15 world. The monetary value calculated above in "Exports" would have to be multiplied by 0.08 to find its purchasing power on the tech-15 world.

Referees will want to exercise some control over the imports that can be obtained: in a Reformation Coalition campaign, imports will obviously be limited to goods that can be produced in the Coalition. However, referees may stipulate that trade relations must first be opened to trading partners via some kind of diplomacy before trade can be attempted, etc.

On-World Trade: In campaigns on already-inhabited worlds, the PC-led group will be able to trade with the on-planet neighbors. Handling these details will be up to the referee, as it should involve roleplayed diplomacy, and should probably involve detailed knowledge of the nature of the goods being traded. Furthermore, such trade might not always be for economic advantage. For example, a PC colony might simply give excess food or manufactured goods to a neighboring group in order to gain their good will.

Set-up Procedures

Several rules affect only the initial set-up of the colony, and these are covered below.

Capital Machinery: All agricultural, industrial, and raw materials capital goods for the laborers in the colony must be transported aboard the colony transports. This equipment is transported at the rate of one displacement ton per Cr4000 of value.

Start-up Rations: Wise colony leaders will bring along rations sufficient to feed the colony for one or more months, until the economy can be gotten up and running. This food is shipped at the rate of 100 rations per displacement ton.

Livestock: Agricultural livestock capital normally paid in the form of rations may not be transported to the colony as bulk food, as it represents living organisms. Animals are brought to the colony in specially designed low berths. These low berths, called livestock low berths, have characteristics identical to emergency low berths. Each livestock low berth carries the equivalent of 10 rations worth of livestock.

Temporary Shelters: It will take a while to build even primitive dormitories, and in the mean time the colonists will need shelter from the elements. Basic tents can provide this shelter or limited time. Housing tentage costs Cr100 and masses 0.001 tonne and displaces 0.002 cubic meter per member of the colony.

Tents may also be used to provide cover for agriculture and machinery, thus letting farming and the other industries get under way immediately. Tents cost 10% of the normal capital construction price for construction and agriculture. They mass 10 tonnes and displace 20 cubic meters per million credits of tentage purchased.

Tents will last for approximately twelve months, at the end of which time they are worn out and are discarded.

Prefabricated Buildings: Housing and other buildings can be carried as prefabricated components and then assembled on the planet. The full price of the building is paid for the prefab components and then 10% of their value must be spent (again) by the construction sector on the planet to assemble them.

Lack of Roads: The necessary roads will not appear instantly, but economic activity will begin almost at once. All economic activity in a hex except for construction will operate at 60% efficiency (construction operates at 100%) until the necessary transportation network is completed. Fortunately, a 500-kilometer TL-0 local transport net appears immediately for free in the colony hex meaning that only resource supply roads need be built right away.

Placement in the Hex: The colony should be placed in one or more 20-kilometer hexes. Each such hex has 350 square kilometers of useable land in it, which must be divided up among raw material production, agriculture, and housing. (Land devoted to industry is included in the housing requirements.) Hexes on the seacoast will have their total area reduced based on how much of the hex is water. Players should make sketch maps of the layout of the colony, being sure to leave room for expansion.

Acclimatization

Acclimatization can be a difficulty if the colonists come from a world that is too different from their destination. The acclimatization stage of colonists has an effect in the economic model (handled in the output roll). Colonists should be rolled for in groups, treating them as NPCs for purposes of attributes. In detailed campaigns where the players have carefully interviewed colonists, the referee may be able to work out aggregate attribute values based on the established characteristics. In other cases, treat industrial, agricultural, and raw materials laborers as having a CON attribute of 6, and treat any troops as their rated NPC class for attributes. Referees and players may stipulate that crucial or detailed NPCs are rolled for individually. Naturally any bonuses for medical personnel in the colony/bootstrap team should be applied.

PLAYING THE COLONIAL ECONOMIC MODEL

The economic model is played in monthly turns, meaning that food, materials, and industrial production is totalled on a monthly basis and assessed against population and the internal needs of the economic sectors.

Month: Because different worlds will have different lengths of day, year, etc., for the purposes of this economic model, the term *month* is defined as approximately 750 hours, plus or minus a few percent to allow the referee to fit it conveniently to local units of time. For example, 750 hours equals 31.25 days each of 24 hours. An Earth month averages 30.4 days. 30.4 days is within 3% of 31.25, so the referee may simply use the existing Terran calendar to keep track of months. As always, the referee is the final judge of these matters.

Annual Considerations

Population Growth: At the end of every year the colonial population grows by 2%. These new laborers may be assigned to any economic sector desired by the colony leaders.

Scenario Conditions/Bookkeeping: Certain colony or bootstrap scenarios may be defined as being a year in duration, or have their criteria for success defined on a yearly basis.

Random Events

Events are rolled for each month at the beginning of the administrative cycle. These include weather events, random events, and scenario specific random events.

Weather Events: The only DMs used on this table are the Weather Factors obtained during the planetary survey. The results are implemented on the current monthly turn.

25	Catastrophic Storm
26	Severe Storm
27	Catastrophic Storm
28	Catastrophic Storm

Drought: Lack of water causes –2 DM on Agricultural output roll for current turn.

Severe Storm: Violent storm damages colony. –2 DM on agricultural out put roll for current turn, plus roll 1D6 for specific result:

1-3: Kills number of colonists and destroys number of units of capital machinery equal to (1D6–colony tech level)×5. Roll for sector, 1-3=agriculture, 4-5=materials, 6=industrial.

4: Destroys (1D20–colony tech level)×500 cubic meters of housing

5: Destroys 1D6×100 stored rations

6: All of the above

Catastrophic Storm: Extremely violent storm damages colony. Agricultural output for current turn cut in half, plus roll 1D6 for specific result:

1-3: Kills number of colonists and destroys number of units of capital machinery equal to (1D20–colony tech level)×10. Roll for sector, 1-3=agriculture, 4-5=materials, 6=industrial.

4: Destroys (1D20–colony tech level)×2000 cubic meters of housing

5: Destroys 1D6×500 stored rations

6: All of the above

Scenario Specific Random Events: The bootstrap and colony adventures in this book show examples of scenario-specific random events tables. These are in addition to the tables above. Referees may create their own random events tables to reflect unique conditions on various worlds.

Satisfaction Indices

Three indices of public satisfaction are tracked: standard of nutrition, standard of shelter, and standard of living. All three are described below, and all three provide a DM to be used on the political table. However, although all three of these DMs are are calculated each month, only the *lowest* (i.e., that with the greatest negative effect) one of these three DMs is actually used on the political table.

However, note that the standard of nutrition does provide a DM on the output roll even if it is not the satisfaction DM being used on the political table.

Standard of Nutrition

The standard of nutrition (SN) is an important index of a colony's well being, as it has two effects. First, the SN level provides a DM on the monthly output roll as an index of the overall health of the population. Second, the SN level may provide a DM on the colony's monthly political roll as a measure of the overall happiness of the population, at least as regards their diet.

Determine the standard of nutrition in the following manner.

Total up the number of rations produced during the month, and determine the amount that are being allocated to the population (as opposed to being set aside for export, the creation of new agricultural capital, stored for future consumption, used for raw materials, used to feed animal-drawn transport or military equipment, traded to local natives, etc.). Divide this number by the total population, and the result is the standard of nutrition, expressed in rations per person.

Random Events

Roll 1D20. On a result of 16+, roll 1D20 on the Random Events table. On any other result, there is no random event for the month. There are no DMs on this table.

Referees should adjust numbers of deaths from plagues, etc., to allow for very small or very large colonies.

D20	*Result*
1	Plague strikes populace: 1D10 persons die each day until Impossible Medical (Diagnosis) task is completed (task may be rolled once per 24 hours). –4 DM on all output rolls this turn. –2 on political roll.
2	Disease strikes livestock: Kills 1D10 units of livestock each day until Impossible Medical (Diagnosis or Veterinary Medicine) task is completed (task may be rolled once per 24 hours). Due to diseased meat, agricultural output cut in half for this turn. –2 on political roll.
3	Plague strikes populace: 1D6 person die each day until Formidable Medical (Diagnosis) task is completed (task may be rolled once per 24 hours). –2 DM on all output rolls this turn. –1 on political roll.
4	Disease strikes livestock: Kills 1D6 units of livestock each day until Formidable Medical (Diagnosis or Veterinary Medicine) task is completed (task may be rolled once per 24 hours). Due to diseased meat, agricultural output reduced by 25% for this turn. –1 on political roll.
5	Hostile starship visits (vampire ship, pirate, slaver, etc., referee's discretion)
6	Vermin eat 1D10×5% of stored rations. –2 on political roll.
7	Blight destroys crops. Agricultural output for turn cut in half. –2 on political roll.
8	Earthquake: 1D6×10% of housing destroyed. –1 on political roll.
9	Vermin eat 1D6×5% of stored rations. –1 on political roll.
10	Crime wave, succeed at Impossible Investigation, Psychology, or Streetwise task or –2 on political roll.
11	Crime wave, succeed at Formidable Investigation, Psychology, or Streetwise task or –1 on political roll.
12	Local carnivore rampages through colony, kills 1D20. Succeed at Impossible Tracking and Hunting task or –2 on political roll.
13	Indigenous animals stampede, destroy 1D20 units of agricultural capital. –1 on Political roll.
14	Crime wave, succeed at Formidable Tracking and combat task or –1 on political roll.
15	No traders arrive this month, no exports sold this turn, all rations set aside for export spoil.
16	Friendly starship visits (referee's discretion)
17	Discovery of tasty local life form. Permanently add +1 to all agricultural output rolls. +1 on political roll this turn only.
18	Population explosion of local edible lifeforms. +4 DM on agricultural output roll for this month. +1 on political roll.
19	Discovery of hardy, prolific, edible, local life form. Permanently add +2 to all future agricultural output rolls. +2 on political roll this turn only.
20	Population explosion of local edible lifeforms. Multiply agricultural output by 2 for this month. +2 on political roll.

THE MONTHLY TURN

Each month, the following things must be done:

1. Roll on the standard random events tables plus the scenario-specific random events tables, if applicable.
   - Assess the impact of the events and play out any roleplaying that is associated with handling these events
   - Assess the impact of the roleplaying or decisionmaking in response to the events
   - Carry forward political table die modifiers from the **previous** turn, such as standard of nutrition, standard of living, standard of shelter, malcontent population, etc.
   - Roll on political table with all appropriate DMs
   - Play out any dictated events from the political table, including roleplaying responses to same

2. Carry forward and total up all DMs that will apply to the output rolls
   - Roll the Agricultural Output roll
   - Roll the Industrial Output roll
   - Roll the Materials Output roll

3. Total up the amount of rations, including those stockpiled and those newly produced
   - Allocate rations to population for the **current** month
   - Allocate rations to other areas, such as animal-powered transportation, ration stockpiles, agricultural production of raw materials, or other purposes, such as frendship donations to neighboring powers, etc.
   - Allocate rations for off-world export
   - Calculate and record the standard of nutrition of the colony used on the **next** turn
   - Carry forward remaining stockpiled rations

4. Calculate the quantity of energy produced, based on the amount of raw materials received, and other inputs for wind, hydro, or solar power
   - Allocate energy to industrial and raw materials sectors for the **current** month

5. Total up the amount of raw materials produced
   - Allocate raw materials to the agricultural, industrial, and energy sectors for the **next** month
   - Allocate raw materials to other areas, such as armed forces, stockpiling, etc.
   - Allocate raw materials for off-world export
   - Carry forward remaining stockpiled rations

6. Calculate the quantity of industrial output produced, broken down into heavy, light, and construction
   - Allocate production to new capital goods, and convert low tech capital to higher level
   - Allocate production to maintenance
   - Allocate production to new infrastructure
   - Allocate production for off-world export
   - Allocate production to armed forces
   - Allocate production of consumer goods to population
   - Calculate and record the standard of living of the colony used on the **next** turn)
   - Calculate and record the standard of shelter of the colony used on the **next** turn)

7. Based on new capital production, calculate new economic capacities for following turn
   - Assess the need for new infrastructure to support load level
   - Reassign laborers within or across economic sectors, if necessary

8. Calculate the amount of currency generated by off-world export
   - Make purchase of off-world goods, equipment, weapons, etc.
   - Make purchase of off-world maintenance

Note that an SN of 2 does not necessarily mean that each person is eating twice as much. Rather, the higher numbers indicate that a greater proportion of the diet consists of luxury foods, or foods from "higher on the food chain." The ration unit is based on the amount of agricultural effort required to create sufficient food to keep a person alive for a month, rather than an absolute mass of edible material. This means that with a given amount of effort, a farmer could produce any of the following: a large quantity of wheat, a somewhat smaller quantity of oranges, a smaller quantity still of beef steak (because each kilogram of beef requires the cow to eat around 10 kilograms of feed), a still smaller quantity of veal, or an extremely small amount of fat goose liver.

Thus we assume that an SN of 1 describes a diet consisting mostly of grain (e.g., rice) or grain products (bread) plus a bare minimum of animal protein and other goodies, while higher SNs indicate a greater and greater percentage of labor- and nutrition-intensive foodstuffs, such as meat and luxury fruits and vegetables.

SN	*Output DM*	*Political DM*
0.45-0.54	–8	–4
0.55-0.64	–5	–3
0.65-0.74	–3	–2
0.75-0.84	–2	–1
0.85-0.94	–1	–1
0.95-1.1	—	—
1.2-2.0	—	+1
2.1-3.0	—	+2
3.1-6.0	—	+3
6.1-10.0	—	+4
10.1+	—	+5

Standard of Shelter

The colony's standard of shelter (SS) is defined as the cubic meters of housing per member of the population. Simply divide the total volume of housing in cubic meters by the total number of citizens. The result is the SS.

The standard of shelter provides a potential DM on the colony's monthly political roll.

SS (m^3)	*Political DM*
25-50	–2
51-80	–1
81-120	—
121-160	+1
161-250	+2
251-350	+3
351+	+4

So Whatcha Gonna Do About It?

Random events in the economic model are a prime example of how high-level play can serve as a "scenario generator" for low-level roleplaying.

If there is a crime wave, the players may wish to take their characters out to capture the miscreants. If a local wild animal is on a rampage, the players may wish to hunt it down personally. If vermin are eating stored rations, the players may try to address the problem themselves. In all of these cases, the creativity of the referee is called into play. The referee must quickly decide how the situation looks in roleplaying terms, and what is required for success, and then place the characters into that low-level framework. If the players succeed amazingly well, the referee may rule that the random event was nipped in the bud and had no effect, its severity is reduced, or that it will not recur on following turns. If they fail, the event takes effect normally. If they fail disastrously, perhaps the event's effects are doubled, perhaps they will automatically recur each month, or perhaps public awareness of the failure will cause adverse DMs on various other tables.

In some cases, the players will wish to hire or appoint persons to serve as extra police officers, guard for grain elevators, etc. Any persons hired for such purposes are treated as armed forces laborers for purposes of the economic model.

Standard of Living

The colony's standard of living (SL) is defined by consumer goods and is indexed on a monthly basis. The SL is determined by establishing the amount of light industrial production that is allocated to the population. These represent various consumer goods, luxuries, and labor-saving devices that are made available to the population. Divide the total monetary value of these goods by the number of laborers, and add this value to the per-person consumer goods already possessed by the populace. This value is then compared to the original per-person value to find its percentage comparison, and is also compared to the value for the previous month, to see if it has increased or decreased.

The population arrives on the world with a base value of consumer goods as shown on the table below (these are brought by each colonist in his or her personal effects, and are assumed to have no volume or mass for shipping purposes). This value declines 2% per month (multiply by 0.98 each month), and must therefore be augmented by new production. The base value of these goods per person varies by tech level as seen by the table below, where "Home TL" is the tech level of the world from which the colonists are drawn.

Home TL	*Consumer Goods*
0-3	Cr5
4-5	Cr50
6-8	Cr250
9-10	Cr500
11-13	Cr1500
14-16	Cr2500

Consult the following table to find the political DM. The table reads out in DMs for increase over last month/decrease since last month. For example, a colony with a base level of Cr500 per person had Cr435 last month and Cr450 this month. Cr450 is 90% of Cr500, so is within 6-10%. The SL increased since last month, so the DM is +1.

Percentage variation from original value	*Above Base*	*Below Base*
Within 5%	—/—	—/–1
Within 6-10%	+1/–1	+1/–1
Within 11-20%	+1/–1	+1/–2
Within 21-30%	+1/–1	+1/–3
Within 31-50%	+1/–2	—/–4
Within 51-100%	+1/–2	—/–5
More than 100%	+1/–3	N/A

Political Roll

The political roll is made monthly and is an index of the current popularity of the colonial leadership. (This roll is intended for use in PC-led colony operations, and is less suited for NPC-led societies, although its use in these cases is up to the referee.) The results of this roll reflect the current attitude of the populace, and this attitude will affect the following output roll as happy people do more work and unhappy people do less.

The roll on the Political table will yield a DM to use on one or more of the output rolls for the current turn, and may direct a change in levels on the Political Track. The Political Track always starts out on Level 3: Good when a colony is established.

Die Modifiers: Die modifiers are provided from other results in this section: from the satisfaction indices, from random events, from low-level roleplaying results, from the monthly persuasion roll, from the political table itself, and from the current level on the political track.

In addition, there are two permanent DMs that can result from the incorporation of criminals or undesirables in the colony population (see the Colony chapter for discussion). For every 1% of the colony population (round fractions up) composed of criminals, a permanent –1 DM. For every 5% of the colony population (drop fractions) composed of undesirables, a permanent –1 DM.

POLITICAL TABLE

D20	*Result and Output DMs*	*Track Movement*
–5	Coup Attempt, –5	Down 2 levels
–4	Severe Riots, –4	Down 2 levels

21	+1 DM, all sectors	—
22	+1 DM, all sectors	Up 1 level
23	+1 DM, all sectors	Up 1 level
24	+2 DM, all sectors	Up 1 level
25	+2 DM, all sectors	Up 2 levels
26	+2 DM, all sectors	Up 2 levels

Dissatisfaction: Small segments of the economy are unhappy with current conditions. –DM shown applies to only one sector (1-2: agriculture, 3-4: materials, 5-6: industrial)

Boycotts/Slowdowns: Small segments of the economy are sufficiently unhappy that they stage work stoppages or disrupt other workers. –DM shown applies to only one sector.

Strikes: Many workers are unhappy and stop work. –DM shown applies to materials and industrial only, not agriculture.

Riot: Groups of the population engage in violence to express their dissatisfaction. –DM shown applies to all economic sectors.

Severe Riot: Rioting causes significant property damage, destroys 1D20 units of capital in any one sector. –DM shown applies to all economic sectors.

Assassination Attempt: As violence continues to escalate, small, disorganized group or individual attempts to kill colony leadership. Referee's discretion, low-level roleplay is recommended. –DM applies to all sectors.

Coup Attempt: Organized group attempts to take over government from current leadership. Referee's discretion, low-level roleplay is recommended. –DM applies to all sectors.

POLITICAL TRACK

Level	*DM*
Level 1: Excellent	+3
Level 2: Very Good	+2
Level 3: Good	+1
Level 4: Fair	—
Level 5: Marginal	—
Level 6: Poor	–1
Level 7: Bad	–2
Level 8: Terrible	–3

DM: Die modifier applied to roll on Political Table on turns when that political level is in effect.

Monthly Persuasion Task: PC colony leaders may make one attempt per month to affect the political roll by using their Charisma-based skills such as Leadership, Persuasion, etc., usually in the form of public addresses. Difficulty level for these tasks is based on how big a DM the PCs are trying for. Outstanding success and catastrophic failure also are determined by the difficulty level. There is no penalty for normal failure.

Using Persuasion and Leadership

The referee should require the player or players to roleplay their presentation, which may involve acting out certain portions of an impassioned plea, but which will certainly require them to recite to the referee what they plan to say. The referee will then have to assess the validity of the speech compared to the reality of the situation and the state of mind of the listeners. If the players' speech is logical, persuasive, stirring, and appears to solve the issues, the referee should reduce the difficulty level of the task accordingly. If the speech completely misses the point, proposes a stupid solution, or otherwise fails to impress the referee, the difficulty level should be increased. In either case, however, the final success is determined by a task roll against the appropriate asset of the PC making the address or aggregate asset of the PC group.

DM	*Diff Level*	*If Outstanding Success*	*If Catastrophic Failure*
+1	Easy	+2	–2
+2	Average	+3	–3
+3	Difficult	+4	–4
+4	Formidable	+5	–5
+5	Impossible	+6	–6

See the persuasion and leadership sidebar for discussion. The persuasion task may only be attempted once per month.

The Output Roll

Roll once for each of the Agricultural, Industrial, and Raw Materials sectors. The result is the multiplier used on the sector's output for that month.

D20	*Output Multiplier*
1	0.80
2	0.85
3	0.85
4	0.90
5	0.90
6	0.95
7	0.95
8	1.0
9	1.0
10	1.0
11	1.0
12	1.0
13	1.0
14	1.05
15	1.05
16	1.10
17	1.10
18	1.15
19	1.15
20	1.20

Die Modifiers

- From Political Track and Political Roll, above
- From Random events, above
- Controlled Economy, DM –1 (see sidebar)
- If population in Acclimatization Stage 1, DM –4
- If population in Acclimatization Stage 2, DM –3
- If population in Acclimatization Stage 3, DM –2
- If population in Acclimatization Stage 4, DM –1
- If population in Acclimatization Stage 5, No DM

Free Market or Controlled Economy?

If you want central economic planning, you lose productivity (during the Output Roll step). If you want productivity and a free market, don't count on getting exactly the economy you planned on. It will go where the bucks are (as determined by the referee). A lanthanum strike can cripple industry as trained machinists head for the hills to prospect.

This is a rather complex topic, because economies are such a complex thing. Face it, no one really understands *real* economies, much less science fiction ones. Fortunately, this is less of a problem than it might seem. Because the scenario model involves a group of player character colony leaders running every aspect of a colony, this is really not a choice; the PCs are running a *controlled* economy.

In cases where the PCs do not wish to run a controlled economy or would rather simply play low-level characters and allow the colonial administration to be run by NPCs, referees must make the various monthly decisions on whatever basis they see fit. These may be entirely rational and workable decisions, these decisions may include sporadic errors to keep a sense of interest and unpredictability, or they may be completely capricious and disastrously incompetent (thereby forcing the PCs to take over control), depending upon the referee's wishes for the campaign.

CHAPTER 5: MASS COMBAT SYSTEM

MASS COMBAT

Throughout a campaign situations will arise where land combat will take place. In some cases the size of the combat will be such that a detailed roleplaying resolution of it will be inappropriate, but the results will be important for the ongoing campaign. For these cases, we present the **Traveller** mass combat rules.

These rules assume that the players are all on the same side, that their actions will be moderated by the referee, and that the opposing force's actions will be determined by the referee.

Scale

Each mass combat turn represents eight hours of time. Movement and combat are plotted on maps using the 20-kilometer mapping hex grid scale (the same scale used in mapping the colony and discussed in the Survey chapter). Units may range from companies, or even smaller detachments, up to divisions, with battalions being the most common force in most campaigns.

Turns

In each 8-hour turn, the referee decides where hostile ground units will move as well as the movement of all friendly units not under the control of the player characters (either because they are outside the player characters' command or are out of communication). Players give orders to friendly units and, in most cases, the friendly units will act on those orders.

Movement is simultaneous by both sides. Following movement the referee resolves all detection, resolves all combat, and determines morale effects, if any. The player characters then receive reports from their units in communication and prepare to issue orders for another turn.

Note that since movement is simultaneous and combat can occur when opposing units enter the same hex, it will sometimes be necessary to pro-rate movement by all units and move them hex by hex to determine if opposing units are in the same hex at the same time.

Rating Units

Each maneuver unit (infantry, cavalry, armor) in the mass combat system has a combat value. This value is usually calculated per maneuver battalion, but it can also be calculated per division (for really large campaigns). If a force smaller than a battalion is used, calculate the value of a battalion and then divide it by the number of smaller units which would comprise that battalion.

For example, a 125-man company is about one quarter of a battalion's strength. To find its strength, calculate the value of the battalion and divide by 4.

Combat value is calculated by selecting a base battalion combat value (BCV) and then applying any appropriate multipliers. The referee decides which of the three base BCVs is appropriate, but the notes in the "Scales of Equipment" sidebar are provided as a general guide.

The referee should feel free to tinker with the base BCV depending on the scale and quality of heavy equipment available. This allows fine-tuning of unit values to take into account different types of units in the same general category (tank and mechanized divisions, for example, would both be considered heavy in most armies) as well as inferior or superior equipment.

Base Battalion Combat Value

Light	*Medium*	*Heavy*
6	10	15

Combat Value Multipliers

Condition	*Multiplier*
Tech Level	1+TL
Novice	0.6
Experienced	1
Veteran	1.5
Elite	2
Division	10

Example: A tech level 5 novice light infantry battalion has a combat value of 6×0.6×6=21.6 (rounded out to 22)

Scales of Equipment

For black powder armies, the difference between light, medium, and heavy infantry is usually a function of how much supporting artillery is available. Armies without artillery are light, armies with light battalion guns in the battalion of separate field batteries are medium, and armies with both light battalion guns and separate field batteries are heavy.

Early animal-mounted cavalry, on the other hand, determine weight almost exclusively by the size of mounts and the amount of body armor carried. Light cavalry usually consists of unarmored troopers mounted on fairly small mounts. Medium cavalry consists of lightly armored troopers (usually equipped only with a helmet) on larger mounts. Heavy cavalry consists of troopers with helmets and some body protection (usually a breastplate, but sometimes just shoulder scales) mounted on the largest mounts available. Horse artillery is never present with light cavalry and should always be present with heavy cavalry.

For more modern forces, weight is generally determined by the proportion of heavy crew-served weapons present in the battalion. Forces with few or no heavy weapons are light, those with a generous allotment are medium, and those consisting exclusively of heavy weapons (usually tank units) are heavy. Powered armor units are almost always considered medium, as are motorized or mechanized infantry. (Even if fairly lightly provided with heavy weapons, a motorized force will carry more ammunition with it and thus be better able to use its weapons over time.)

Combat value multipliers are determined by the tech level of the unit (the multiplier is the unit's tech level plus 1), its average level of NPC experience (as shown on the table below), and its size (divisions multiply the battalion strength by 10; companies multiply battalion strength by a fraction determined by the referee, depending on the size of the company). After all multipliers have been applied to the BCV, any fractional results are rounded to the nearest whole number (rounding fractions of 0.5 up). No BCV may ever be reduced to 0 by rounding, however, and so fractional BCVs of less than 0.5 are retained as fractions.

The final value of the unit, once all multipliers have been applied, is its Combat Value (CV). Battalion BCVs and multipliers are listed on the table at lower left.

Mobility

Units' movement is expressed in hexes moved per 8-hour turn. The mobility of the unit is determined by the travel movement of the slowest vehicle in use in the unit. Divide the travel movement rate (in kilometers) by 25 to determine the mass combat system movement in hexes per turn.

The following table lists common movement allowances for low-tech units, and may be used as a general guide to movement rates of hostile forces. The first number is the number of hexes moved per turn on a road or, in the case of helicopters and lift units, in high mode. The second number is the number of hexes moved cross country or, in the case of helicopters and lift units, in NOE mode.

Type	*Movement*
Infantry	2/1
Cavalry	3/2
TL 5 Motorized	5/2
TL 6+ Motorized	15/5
Mechanized/Armored	10/5
ACV	20/15

Terrain: Some terrain is more difficult to move through than others and so slows movement. The Terrain Effects Chart (TEC) lists most common terrain types encountered and their movement costs. Terrain types with a dash are moved through normally, while those with a number following the multiplication sign cost additional movement. These movement costs vary with the type of unit actually moving through the hex. Hill terrain, for example, has no special cost for track-mobile, ACV-mobile, and lift-mobile units. Leg-mobile and wheel-mobile units, however, count the hex as two hexes for movement.

Units which do not have sufficient movement left to enter a hex may not do so, but may expend their remaining movement toward the entry cost of the hex for the next turn. (It would otherwise be impossible for infantry to enter any difficult terrain.)

Units may move along roads at the road movement rate, regardless of the type of terrain in the hex. The presence of a "P" on the chart indicates prohibited terrain; units with that mobility type may not enter the hex (except on a road).

Supply and Fatigue: A unit's ability to move is constrained by supply and fatigue. Supply limits a unit's movement usually due to fuel limits. Vehicles which have limited fuel must spend a turn refueling after they have expended their normal load. Troops may rest while refueling. Fatigue limits all units, and while the specific effects of fatigue are covered later, it is normal for a unit to rest for one turn per 24-hour day.

Deploying: A unit which does not move during a turn is considered to be deployed in the hex it occupies, and should be so noted. A deployed unit has advantages in combat, detection, and blocking enemy movement. A unit may rest at the same time that it is deployed.

Leaving an enemy hex: Units may begin the turn in the same hex as an enemy unit and may use movement to withdraw from the hex. Several special rules govern this movement, however.

If movement through the hex has been blocked, units may only leave the hex across the same hexside they entered. If other friendly units are in the hex at the start of the turn and they entered across different hexsides, units may withdraw across those hexsides as well.

If there are no friendly units left in the hex at the end of the turn but there are still hostile units there, all hostile units in the hex may conduct pass-by fire at the unit or units which withdrew. All hostile units may conduct only one pass-by fire at withdrawing units, however, not one attack against each withdrawing unit.

Detection

Players should not be told the location of enemy ground combat units unless they are detected by a friendly unit in communication with other friendly units (and ultimately the players). Detection of aircraft by electronic sensors or detection from orbit is resolved using the normal detection rules in the game. A special procedure is used for detection of ground units by hostile ground units, however.

Detection takes place when two opposing units enter the same hex. Units moving by road or in high mode are automatically detected. Other units may be detected if a successful task roll is made.

Detection is resolved immediately, as detection of an enemy unit may stop movement and initiate combat. Detection is a standard task roll using the asset level of the average NPC quality of troops in the unit (Elite = 15, Veteran = 13, Experienced = 11, Novice = 9, as noted on TNE page 59). Detection is a Difficult task, and the difficulty level is modified as shown on the following table. The terrain occupied by the unit affects the difficulty of detection. The difficulty levels are noted on the TEC. For other modifying conditions + numbers are increases in the difficulty level while – numbers are decreases.

Condition	*Modifier*
Heavy detecting unit	+2
Medium detecting unit	+1
Target less than a battalion	+1
Light target unit	+1
Night or inclement weather	+1
Detecting unit deployed	–1
Target a division or more	–1
Heavy target unit	–1
Every 2 tech levels detector is above target	–1
Terrain	see TEC

Blocking Movement

A unit may block movement of enemy units through its hex if it detects them and if it has sufficient combat power to control the hex. Each hex has a control value listed on the TEC, which is the total combat value needed to insure that enemy movement is blocked. The combat value of deployed troops counts double for purposes of blocking enemy movement.

If the enemy unit is not detected, there is no possibility of blocking its movement and forcing combat.

If the moving unit is detected and the opposing player has combat value in the hex equal to or in excess of the hex's control value, enemy movement may be blocked at the option of the detecting player.

If the moving unit is detected and the opposing player has less combat value in the hex than the hex's control value, that player may attempt to block movement by rolling a D20. Divide the total combat value of the detecting player's units in the hex (remembering to double the value of deployed units) by the control value of the hex, and then multiply the result by 5, rounding to the nearest whole number. The final result is the number or less needed on a D20 roll to successfully block movement.

If movement is blocked, neither side continues moving and combat takes place in the hex.

Aircraft and lift units in high mode can never have their movement blocked by enemy units.

If movement is not blocked but the moving unit is detected, the detecting unit may conduct pass-by fire (see below).

Withdraw Before Combat

If one player detects an enemy unit and is faster than that unit, it may withdraw prior to combat. If it is itself detected, the opposing units in the hex may conduct pass-by fire on the unit as it withdraws. The withdrawing unit is subject to the normal restrictions on leaving an enemy-occupied hex, and they automatically are subject to pass-by fire from the hostile unit in the hex, even if it does not remain in the hex. Withdrawing units may never withdraw from the hex across a hexside used by a hostile unit to enter the hex, and if the hostile units are strong enough to block movement through the hex the withdrawing unit must exit the hex across the hexside used to enter the hex.

Withdrawal before combat aborts any other scheduled move of the withdrawing unit, although it may continue to withdraw in the face of an advancing enemy unit within the limits of its movement allowance (withdrawing back up its original path of movement to the contested hexes). If in withdrawing it moves into another enemy-occupied hex it may not withdraw before combat again that turn.

Combat

Combat takes place after movement, and consists of all units of both sides firing at detected enemy units in the same hex. The referee first determines the order of fires, and then resolves them in order.

Order of Fires: The order of fires is determined by detection, tech level, terrain, and troop quality. Order of fire is important, as casualties are removed as soon as a unit fires. As casualties are expressed in terms of combat value, casualties reduce the ability of the unit to cause casualties when it is that unit's turn to fire.

If one sidesæ units are undetected, those units automatically fire first before any hostile units in the hex.

If both sides' units are detected, units fire in the order of their tech level, with highest tech units firing first.

If both sides have detected units of the same tech level, deployed units fire first if occupying First Fire terrain. First Fire terrain consists of rough, mountains, swamps, forest/jungle, and broken, as noted on the TEC.

If both sides have detected units of the same tech level, and are not deployed units in first fire terrain, units fire in order of troop quality category, with elites firing first.

If both sides have detected units of the same troop quality and tech level, and are not deployed units in first fire terrain, the units fire simultaneously.

Allocating Fires: A unit must divide its fire as evenly as possible among the enemy units in the hex if they have detected it. If a unit has not been detected it may (but is not required to) fire at any enemy units in the hex it desires. However, any unit which a unit fires at may fire back. Units which have not previously detected a firing unit fire back using the "firing at undetected unit" penalty noted below.

Fire Resolution: To fire a unit, either the referee or a player rolls a D20, multiplies the result by the unit's combat value (CV), and then multiplies that result by 0.01, rounding fractions to the nearest whole number. The result is the casualties suffered by the target unit and this amount is subtracted from its combat value. This result, however, is modified by terrain and by certain other conditions of that target unit.

Terrain effects are listed on the TEC. Terrain either has no effect on fire or halves casualties. The effects listed are different for deployed units and moving units, and apply to fire delivered by the listed unit, not against it. For example, a moving unit in a mountain hex has the casualties caused by its fire halved, while a deployed unit does not.

Other effects related to the target unit are summarized below, and are additional multipliers to the total casualties suffered by the unit.

Target	*Effect*
Deployed	x0.5
Deployed in fortifications	x0.25
Undetected	x0.5
Pass-By Fire	x0.1
Fired on by routed unit	x0.1

Hit and Run

If a unit is undetected at the start of combat but has detected an enemy unit in its hex, it may conduct a hit and run attack. In a hit and run attack the attacking unit always fires first but multiplies its CV by 0.5 (in addition to all other multipliers). The target unit is allowed to fire back, but multiplies its CV by 0.1 (instead of the normal 0.5 multiplier for firing at an undetected unit). The attacker then must withdraw from the hex, that hex of movement being counted against itsnext turn's movement.

Morale

As units suffer casualties, their morale begins to falter. Better troops are more stoic under fire, and so can stand more casualties before collapsing, but eventually any unit can break and run, or even surrender.

Morale is determined each turn, and is based on the casualties suffered by a unit that turn as a percentage of the unit's strength at the start of the turn. For example, a unit which started the turn with a CV of 10 and which suffered losses of 2 CV would have suffered 20% losses in the turn.

There are three possible adverse morale effects triggered by casualties: retreat, rout, and surrender.

Retreat: When a unit takes casualties in a turn equal to its retreat number, it must break contact with the enemy and move away. This movement takes place at the end of the turn and the movement cost to leave the hex is counted against the unit's next turn's movement. All of the normal restrictions on leaving an enemy-occupied hex are in effect, including the possibility of pass-by fire if no friendly units are left in the hex.

Rout: When a unit takes casualties in a turn equal to its rout number, it must break contact with the enemy and move away. This movement takes place at the end of the turn and the movement cost to leave the hex is counted against the unit's next turn's movement. All of the normal restrictions on leaving an enemy-occupied hex are in effect, including the possibility of pass-by fire if no friendly units are left in the hex.

Routed units remain routed until they have had two consecutive turns of rest. When routed units fire, multiply all casualties inflicted by 0.1.

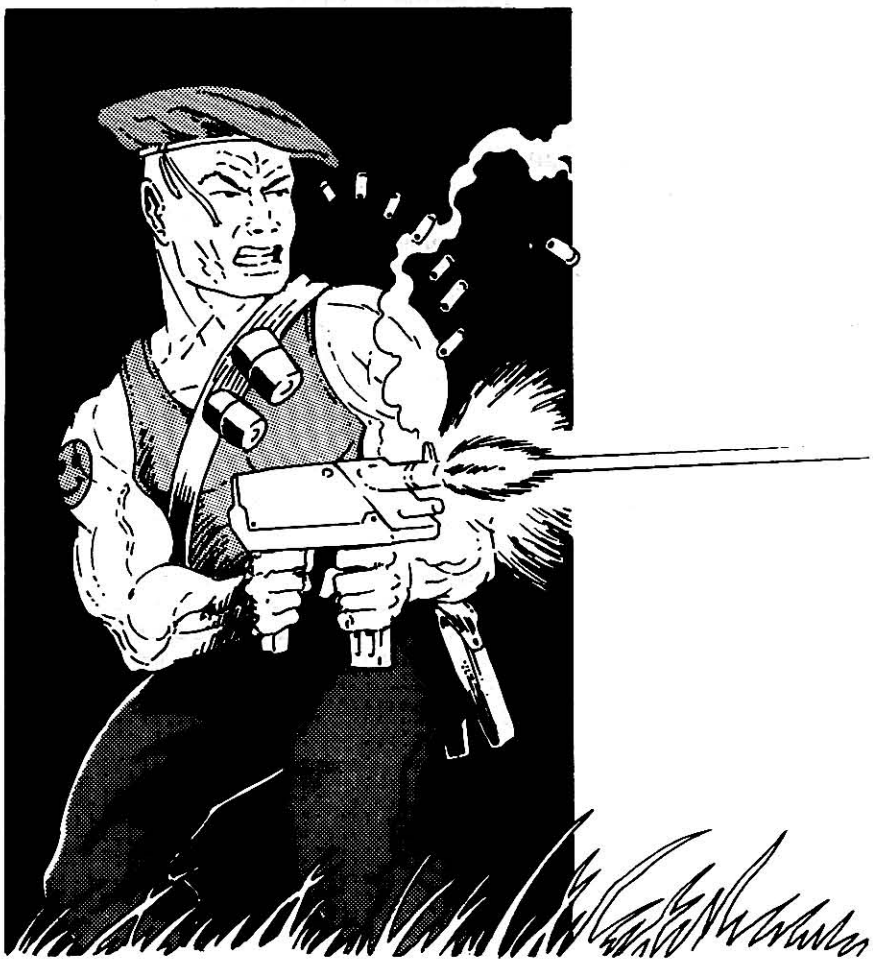
Surrender: When a unit takes casualties in a turn equal to its surrender number, it immediately surrenders, even if this prevents it from firing in its part of the turn. Units which would normally suffer casualties in excess of their surrender number suffer only casualties sufficient to cause surrender and then give up.

Morale Levels: The retreat, rout, and surrender levels of units are determined by their troop quality rating, as shown on the table below.

Type	*Retreat*	*Rout*	*Surrender*
Novice	5%	10%	20%
Experienced	10%	20%	40%
Veteran	15%	30%	60%
Elite	20%	40%	80%

Fatigue

Units which fight a battle are fatigued until they spend a turn resting. In addition, units not in combat which do not rest for one turn per day are fatigued. Each condition which causes fatigue (i.e. each battle fought and each day spent without rest) increases the fatigue level of the unit by 1. Each turn spent resting reduces the fatigue level of the unit by 1.



In addition, units which are fighting in planetary environments to which they are not acclimatized suffer fatigue according to the following chart. Note that these fatigue levels cannot be removed by rest, but are permanent until the personnel become acclimatized. (See pages 13-14 of the Survey chapter for more details on acclimatization.)

Acclimatization Stage	*Fatigue Levels Added*
1	4
2	3
3	2
4	1
5	0

Each fatigue level reduces the casualties caused by the unit in fire combat by 10%. In other words, units at fatigue level 1 multiply their CV by 0.9 (in addition to all other modifiers), while units at fatigue level 4 multiply their CV by 0.6.

Units which are greatly fatigued have their morale reduced. For every two fatigue levels, treat the unit as one troop quality level lower for morale purposes. An elite unit at fatigue level 5, for example, would have morale levels determined as if it were an experienced unit.

No unit may be reduced below novice morale level. Any unit with a fatigue level of 10 or more automatically surrenders to any enemy unit it encounters.

Supply

Although supply is critical to sustained combat, it is very easy to become completely absorbed by logistics to the exclusion of other game considerations. As a result, only the simplest of supply rules are presented here.

Types of Supply: There are three types of supply considered in the game: rations, fuel, and munitions.

Each unit requires rations once per day, and the rations are used when the unit is resting. If the unit does not receive its rations for the day, it has its fatigue level increased by 1. Units which are already fatigued and which are resting for more than one turn are denied the beneficial effect of one turn of rest per day if they receive no rations. There are no additional effects from lack of rations.

Fuel is required each time a vehicle uses up its onboard fuel. Units fuel all of their vehicles at once and usually do so while resting. Fuel supply must be available while the unit is resting in order for the vehicles to refuel.

Munitions are used when a unit fights. Whenever a unit fights it uses munitions and must receive more to fight at full effectiveness. Once a unit fights, multiply the casualties inflicted by it by 0.5 in all future combats until it receives munitions. Munitions are received at the beginning of a turn; the receiving unit does not have to rest to receive munitions.

Tracing Supply: Units are in supply if they can trace a supply line back to a friendly supply base. The supply line should be shorter than one turn's move-

ment of the army's supply movement rate (as calculated on pages 33-34 of the Economy and Infrastructure chapter). If it is longer than one turn's movement, units which require supplies may or may not receive them, based on the following table. The number under the die roll column is the roll (or less) needed on a D20 for a unit to receive supplies.

Distance	Die Roll
2 turns	16
3 turns	12
4 turns	8
5 turns	4

Each unit rolls separately to determine whether or not it received supplies.

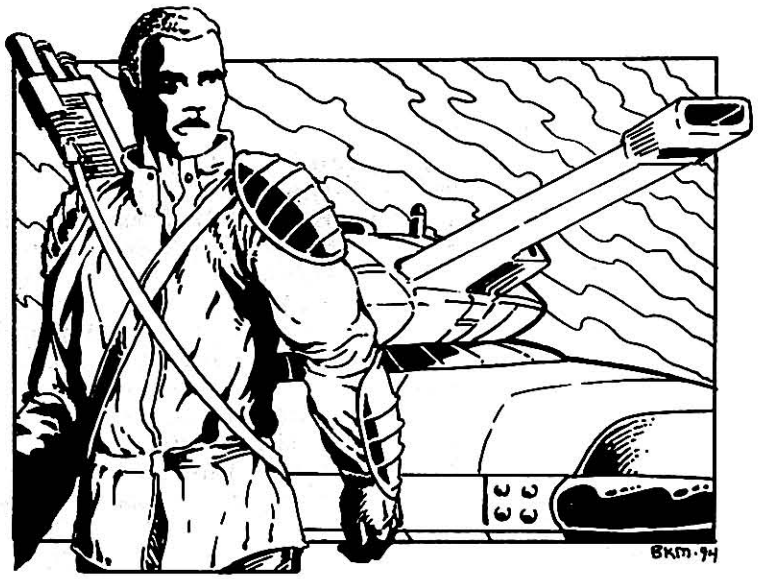
Terrain Effects Chart

	Combat				Movement				
Terrain	Dep	Mov	Detect	Cntrl	Leg	Wheel	Track	ACV	Lift
Clear	—	—	—	200	—	—	—	—	—
Prairie	—	—	–1	300	—	—	—	—	—
Rough	FF	—	—	100	×2	×2	—	—	—
Mountain	FF	½	+1	50	×2	P	×4	P	—
Marsh	—	—	—	100	—	×4	×4	—	—
Swamp	FF	½	+1	100	×2	P	P	—	—
Forest	FF	½	+1	300	×2	×4	×2	×4	—
Jungle	½	½	+2	500	×2	P	×4	P	—
Desert	—	—	–2	500	×2	×2	—	—	—
Broken	FF	½	+1	100	×2	×4	×2	×4	—
Glacier	—	—	–2	500	×2	×4	×2	—	—

Supply Bases: Players may establish supply bases wherever they like in friendly territory. Any city hex containing industrial laborers (ILs) is also considered to be a supply base. If a move into enemy territory is required it will probably be necessary to establish additional forward supply bases to sustain the move.

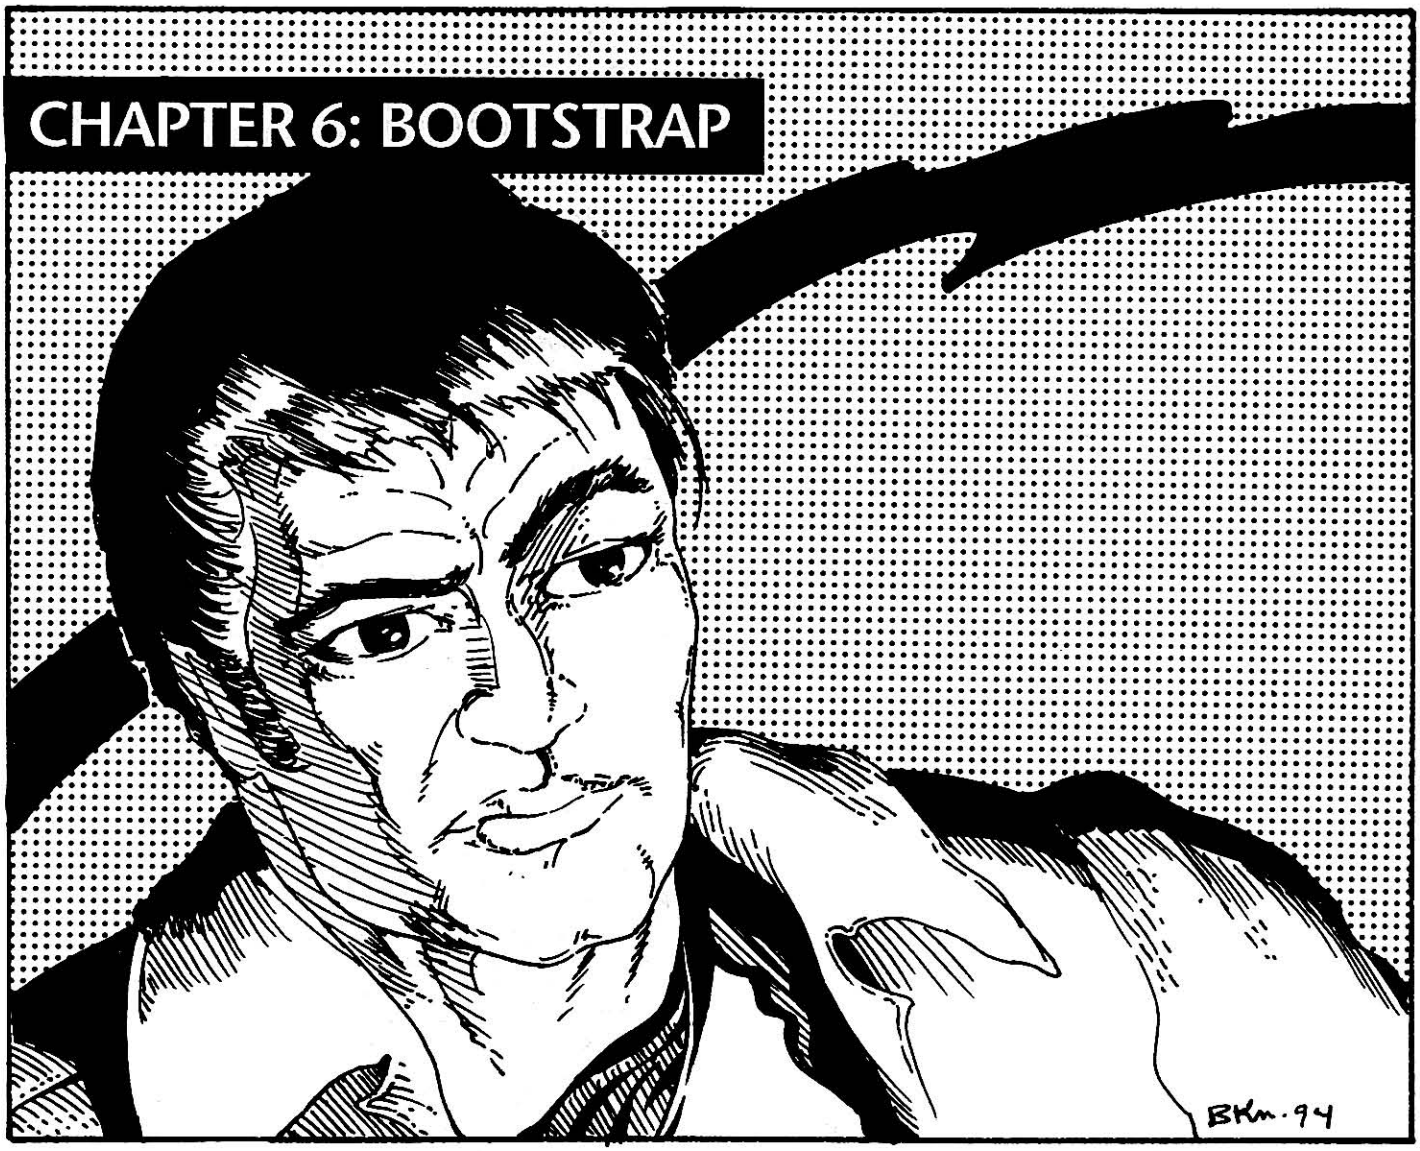
In order to create a new supply base, the player must tell the referee where the base is to be and then spend three turns "stocking" it. Once supplies have been available to the hex for three consecutive turns, the base is operational.

If a supply base ever goes for six consecutive turns without receiving supplies, it is no longer an active supply base.



Integrating Supply with the Economic Model: The goods supplied to friendly military units in the supply system above are the same goods which are allocated to the Armed Forces sector using the guidelines in the Economic Model chapter. The intent of the following paragraphs is to translate how these goods are used up in the mass combat system. It is not intended that these supplies be tracked in a painstaking manner. Rather, these guidelines should be used to allow the referee to determine if a society has a sufficient supply base to continue prosecuting a war without concern, or if it must be penalized for not having allocated sufficient resouces to its armed forces, such as ammunition or operating hours of fuel.

Rations: So long as sufficient rations are provided to the Armed Forces Laborers in the economic model, there will be sufficient supply to push forward to the troops in accordance with the supply rules above.



Munitions: Consumable ammunition is purchased for each weapon in the economic model, and this ammunition must be replaced when it is used up in combat. For purposes of this model, each turn of combat consumes ammunition at the rate of 25 times the weapon's basic rate of fire for all weapons in the unit, except for guided missiles, which are consumed at the rate of 5 rounds per launcher (or, in the case of disposable package launchers, 5 rounds per soldier/vehicle primarily equipped with this weapon). The rate of fire used for these purposes is the standard ROF listing in the TNE equipment tables. For SA and automatic weapons, do not multiply this rate by 5 for the maximum possible number of shots; therefore a ROF of SA is treated as 1, and an automatic ROF of 5 is treated as 5. For weapons with a reload rate, add one to the rate and invert it to serve as a fraction. Thus a weapon with a reload rate of two would become a ROF of ⅓ for these purposes.

Thus a colony which intends for its armed forces to be able to fight for one 750-hour month with one eight-hour turn of combat per day (assuming 24-hour days) must purchase or produce ammunition sufficient for (31.25×25=) 781 rounds per weapon or vehicle with a rate of fire of 1 shot per combat turn, 3906 rounds per weapon with a ROF of 5, or 39,063 rounds per machinegun with a ROF of 50.

Fuel: Raw materials in the form of fuel are provided to the armed forces on a monthly basis, and are expressed in the number of hours of operation that this allows to the armed forces per month (based on the assumption that all of their equipment is being operated simultaneously). As each turn in the mass combat system is eight hours, it is simple to calculate the rate at which fuel is used up. It will be useful to divide the total monthly hours of operation by eight, and then by the total number of battalions to find the total amount of fuel in battalion-turns. Each turn that an in-supply battalion moves or fights, it uses a battalion-turn of fuel. Each turn that an in-supply battalion does not move or fight, it uses ½ a battalion-turn of fuel. Only out-of-supply units use no fuel, and units may *not* be voluntarily placed out of supply merely to save fuel.

CHAPTER 6: BOOTSTRAP

A CHANGE OF PACE

It's good to be back in the RC, even Oriflamme. It's nice not being shot at. And its nice to have some cash in your pocket after Auction. But your group is tired. Tired of too many hot DZs, too many SAG raids, too much killing and death. You've reaped the rewards, but you need something else. Something less deadly, something life affirming, something where you can build a future. After all, future building is what it's all about in the New Era—right?

You are in your hotel lounge one evening, with one eye on the newscast while you try to figure out what to do next. After the news anchor runs through the usual traffic accident and ship arrival stories, she cuts to a feature on a world named So Skire. After wide shots of peaceful vistas and friendly natives harvesting their fields, the field reporter comes on camera with members of the So Skire survey team who have just landed back on Oriflamme.

"We've found a rich world here, ripe for development," the team leader says, "With a little help, So Skire could be an excellent trading partner with the Coalition."

After more wide vistas of green fields and snow-capped peaks, the camera cuts to a tight shot of the field reporter.

"This is one lucky freelancer," she says. "The RCES announced this morning that they've bought his data packages and they are preparing a bootstrap expedition to the Dawn Isles, a friendly country in So Skire's tropics. First reports say So Skire could be a good resource world, and if we are going to have allies on the Back Side of the Coalition, this would be a good place to start."

The RCES owes you a few favors. Particularly Jerszy Kaminski, the local detailer, since you led the SAG raid that busted his son out a desert dungeon on Keipes and caught a slug in your thigh in the process. The next morning you call his office and make an appointment for lunch.

Jerszy "Crusher" Kaminski

Veteran NPC

Combat Assets: Slug Weapon (Rifle & Pistol), Armed Martial Arts (Large Blade), Unarmed Martial Arts, Archery

Other Assets: Leadership 12, Persuasion 12, Ground Tactics 10, Recruiting 8, Liaison 8, Language 8, Admin/Legal 8, Riding 6, Instruction 6, History 6

Motivation:

Club Queen: Kaminski handles a problem by lowering his head and charging into it, not stopping until the problem or situation is resolved. He has a reputation throughout the RCES: if something critical really has to be done, give it to Kaminski.

Spade 10: Kaminski embodies the RC's philosophy of being the agency to reunite humankind. He wants to personally bring as many planets as he can into the RC and restore civilization to the stars before he dies.

Bootstrap n. 1. A strap on a boot for pulling it on. adj. 2. To cause to succeed without the help of others. 3. To achieve success by one's own unaided efforts. 4. To help others help themselves, as in a bootstrap operation.

HIRING ON

The player characters meet with "Crusher" Kaminski in a pleasant restaurant atop an office building near the downport and the RCES offices. At the referee's discretion, he can remember some good work the PCs have done for him in the past (as in the introductory passage above), in which case he can be looking forward to be working with the PCs again. Alternatively, the PCs may be unknown to him, and will have to work to impress him by some combination of roleplaying, interaction tasks, presentation of credentials, etc. If Kaminski warms up to the PCs, he says, "If you decide to sign on, you'd better put your affairs in order, because you're going to be away for a long time. This is no hot recovery. You'll be going to a place called So Skire where the natives are sort of friendly but go around wearing iron pants and throwing spears at each other. Expect to be there at least a year.

"So Skire is important to us for a number of reasons. First, it's a dense world and the ore samples taken so far look very interesting. So Skire seems to have a great potential as a heavy metals and rare earths source.

"Second, if the local humans can be brought back into interstellar society, they would be a great market for higher tech manufactured goods, and help revive trade and commerce in this area.

"Third, So Skire is at the coreward end of the So Skire Main, a huge cluster of 66 worlds that are accessible by jump-1 transportation. They run all the way rimward into Alpha Crucis and trailward along the Old Expanses-Alpha Crucis border into Spica. Some of these worlds are ripe for recontact and fairly advanced. Hiver reports and initial scouting has located one at TL-9, and several others at 6, 7, and 8. If we can establish a foothold on So Skire, we could have an the ideal base for expanding into the main. It could also help support Baldur's new colony on Poyzen.

"And just as importantly, a base here will help bridge the gap in the Wilds toward the Hiver worlds.

"*Immanuel Kant* will be leaving here in a month and will meet up with *Trigger* at L'Steich for the trip over. We want you on board. The fact that the Coalition is using their brand new clipper for this mission ought to tell you how important they think this job is."

If the PCs agree to sign on, Kaminski takes them to his office.

"Here's the data we have on So Skire so far," he says, while projecting a map of the world on the wall. He hands each PC a copy of the RCES scouting report compiled from the free-lancer's survey. The referee should make at least one set of photocopies of pages 57 through 60 available to the players to examine. GDW grants permission to owners of the **World Tamers Handbook** to photocopy these briefing pages for these purposes.

After the players have had a chance to read the data sheets for a few minutes, Kaminiski pulls some forms from his desk drawer and says, "Interested? If you are, here's a one-year contract for your services that can be extended as needed. If you're tired of sitting around on Oriflamme, here's a chance for some real adventure, not just a quick drop and recovery."

He offers the PCs a pen and says, "The rest is up to you."

REFEREES' SECTION
PLAYERS DO NOT READ BEYOND THIS POINT

At this point, the adventure can proceed in one of two ways, depending on your players capabilities and interests, and whether you are playing a primarily high level or low level campaign. Throughout this campaign at appropriate locations you'll see suggestions for using your players in a high or low level campaign. In the first example below, high level players become involved in the complexities of recruiting NPCs. Low level players simply sign on with the expedition under the leadership of NPCs.

High Level

If the PC group is to be the leaders of the bootstrap expedition, they meet Kaminski for lunch and make a deal with him to lead the operation. The objectives of the operation should be discussed as well as its duration. Rewards, in keeping with the usual modest Reformation Coalition standards for these things, can be talked about here too. The next step will be finding and recruiting some 100 bootstrap specialists and travelling to So Skire.

Low Level

If the PC group is looking for jobs on the expedition, Kaminski will be the one doing the recruiting. He will also be leading the operation. For players with a military background, there is plenty of opportunity for work as intelligence specialists, as military advisors to the Dawn Isles ground forces, as naval advisors to the Dawn Isle Wet Navy, and as members of the expedition's security team.

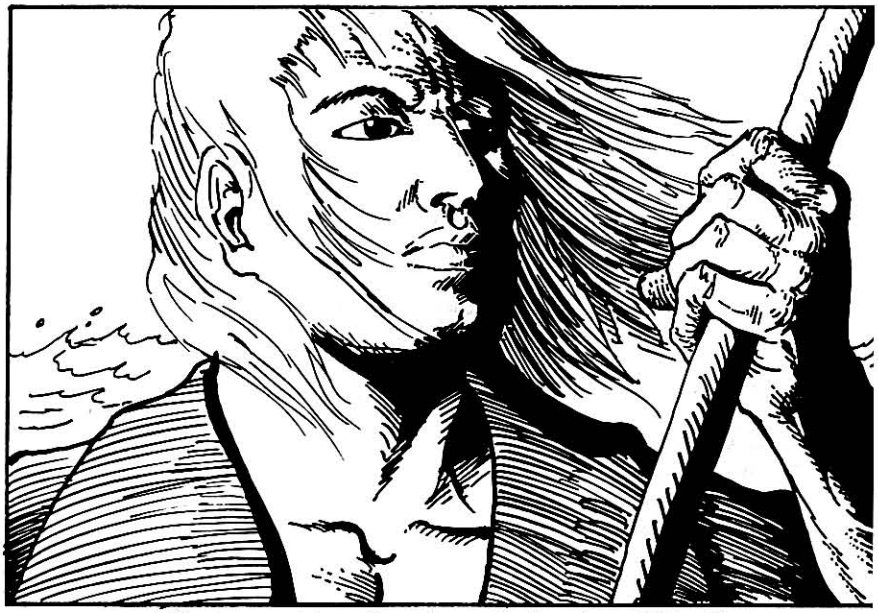
REFEREES' INFORMATION FOR THE PLANET SO SKIRE

Armed Forces of the Woden Empire

Total Personnel: 300,000
Wet Navy: 48,000 (Experienced crews)
32 major combatants (TL-1)
Ground Forces: 252,000
9 divisions of foot (3 TL-1 Experienced, 6 TL-1 Novice)
2 mounted divisions (TL-1 Veteran with 5 cavalry squadrons each)
5 separate cavalry squadrons (TL-1 Veteran)
1 Imperial Guard division (TL-1 Veteran)

Armed Forces of the Dawn Isles

Total Personnel: 200,000
Wet Navy: 64,000 (Veteran crews)
40 major combatants (TL-1)
6 other combatants (TL-1)
Ground Forces: 136,000
5 divisions of foot (TL-1 Experienced)
2 cavalry brigades (TL-1 Experienced)
1 amphibious brigade (TL-1Veteran)
2 Marine battalions deployed as ship's troops (TL-1 Veteran)
1 arquebusier battalion (TL-2 Elite)



Armed Forces of the Southern Republic

Total Personnel: 150,000
Wet Navy: 48,000 (Experienced crews)
32 major combatants (TL-1)
Ground Forces: 102,000
1 Marine division (Ship's troops, TL-1 Experienced)
3 divisions of foot (TL-1 Novice)
1 cavalry division (TL-1 Experienced)
1 Brotherhood Guards battalion (TL-1 Veteran)

Armed Forces of the Aylward Islands

Total Personnel: 100,000
Wet Navy: 16,000
32 regular combatants
Ground Forces: 84,000
1 amphibious division (TL-1 Experienced)
3 divisions of foot (TL-1 Experienced)
2 marine battalions (TL-1 Veteran)

So Skire Minor Powers Armed Forces

Nation	*Wet Navy*	*Regular Combatants*	*Patrol Craft*
Borean Enclave	6400	10	6
Svensholm	8800	10	15
South Dawn	8800	12	11
Ragnar	400	0	2

Nation	*Ground Forces*	*Division Equiv.*	*Battalion Equiv.*
Borean Enclave	73,600	3	7
Svensholm	101,200	5	0
South Dawn	46,200	2	3
Ragnar	4,500	0	2

Survey Data on the Dawn Isles

The brief free-lance survey conducted on So Skire did not get detailed survey data on the Dawn Isles. If the PCs elect to conduct their own survey, the following data will be obtained of the three planetary hexes shown in the map on page 79. The referee may elect to run a detailed campaign using elements of the economic model detailed in Chapter 4, in which case this data will be necessary.

Planetary Hex: Northern Aaland

Agricultural Richness: 1.3
Agricultural Useable Area: 60%
Raw Materials Richness: 110
Raw Materials Useable Area: 35%
Fossil Fuels: Yes
Radioactives: Yes
Extractable Hydro Power: 4200 kW per 20-km mapping hex
Extractable Wind Power: 88.2 MW per 20-km mapping hex
Base Latitude Temperature: +10°C
Summer Maximum Temperature: +21°C
Winter Minimum Temperature: –9°C
Weather Factors: 0

Planetary Hex: Southern Aaland and Northern Gotland

Agricultural Richness: 1.3
Agricultural Useable Area: 50%
Raw Materials Richness: 120
Raw Materials Useable Area: 40%
Fossil Fuels: Yes
Radioactives: Yes
Extractable Hydro Power: 3360 kW per 20-km mapping hex
Extractable Wind Power: 117.6 MW per 20-km mapping hex
Base Latitude Temperature: +16°C
Summer Maximum Temperature: +23°C
Winter Minimum Temperature: +4°C
Weather Factors: 0

Planetary Hex: Southern Gotland

Agricultural Richness: 1.6
Agricultural Useable Area: 60%
Raw Materials Richness: 90
Raw Materials Useable Area: 30%
Fossil Fuels: Yes
Radioactives: Yes
Extractable Hydro Power: 3780 kW per 20-km mapping hex
Extractable Wind Power: 137.2 MW per 20-km mapping hex
Base Latitude Temperature: +22°C
Summer Maximum Temperature: +29°C
Winter Minimum Temperature: +10°C
Weather Factors: 0

So Skire's Governments

Nation	*Population (in millions)*	*Government*	*Corruption*	*Talent*	*Cruelty*	*Paranoia/ Aggression*	*Xenophobia*

South Dawn	5.50	4-CD	Low	High	Low	Low	Low
Ragnar	0.50	1-TG	High	Low	High	High	High

RECRUITING (HIGH LEVEL)

Bootstrap teams are a mix of civilian specialists and military personnel who have been seconded to the RCES. All are volunteers. They have many motives. Some are looking for adventure. Others genuinely want to help people. Still others need a convenient way to get off-planet for an extended period of time.

Team Composition

There are four categories of bootstrap team members to be recruited. These include team leaders, technicians, military advisors, and security specialists (see the table on page 62). Because of the nature of the bootstrap mission, all team leaders, technicians, and military advisors should have significant Instruction skills in addition to any other skills listed below.

Team Leaders: These are volunteers with useful professional skills. They would be commissioned characters (where appropriate) drawn from careers such as Law Enforcement, Medicine, Veterinary Medicine, Civil Engineering, and Science. Retired or serving Army or Marine officers would also be included in this category.

Altogether there are 7 professional leadership slots available. The referee should roll up detailed professional NPCs for the players to consider for the leadership slots. In addition to considering their career qualifications, the players should interview these NPCs in depth to examine their motivations as well as their skills. Remember, the PCs and these NPCs will be working closely together for a long time.

Team leader jobs to be filled include Team Commander, Deputy Team Commander, Chief Scientist, Chief Medical Officer, Chief Agronomist, Senior Military Advisor, and Chief Security Specialist.

Note that these are job slots that may be partially or entirely filled by the player characters. If there are not enough PCs to fill these jobs, the remaining slots must be filled by NPCs.

Technicians: These are civilian team members with useful technical skills. These include skills from Medical, Engineer, and Physical Science clusters, particularly Farming. These may come from any career but must have proficiency in one of these skills. Successful candidates should also have good Interaction skills because their primary job will be "winning the hearts and minds" of the local population and teaching them their skills. There are 35 technician job slots available. The referee should create these as Experienced template NPCs, assigning them skills from the Technician , Artisan, Physical Science, Social Science, Interaction, or Engineer skill clusters. If desired, the players can select higher skilled individuals and generate complete UPP attributes and skills as part of interviewing prospective team members.

Military Advisors: These are experienced military professionals skilled in modern and archaic weapons who will serve as field advisors as well as drill instructors with the host government's armed forces. Create these by using the Star Viking Ground Specialist and Regency Marines NPC templates on TNE pages 65 and 66. Military advisors must have skills in Archery, Thrown Weapon, Archaic Artillery, Early Firearms, both Unarmed and Armed Martial Arts, Leadership, Instruction, Persuasion, and Ground Tactics. See page 63 for more details on the integration of these skills with the mass combat system.

There are eight military advisor job slots available. They will work closely with the Dawn Isles armed forces training them in the tactics needed to get the most efficient use out of their TL-1 weapons and introducing an increasing amount of TL-2 technology—principally musketry and black powder artillery—so they will be strong enough to repel an invasion from the Woden continent. It is hoped that this display of technology will attract other armed forces and their leaders to the Dawn Isles banner. In addition to retired and seconded officers and senior enlisted personnel from the world armies and wet navies of the Coalition, a detachment of RC Marines from the 3rd Battalion, 3rd Brigade is available as training specialists.

Security Forces: Even though all bootstrap personnel will be armed with their personal weapons, experienced troops are needed to provide security if the team suddenly finds themselves on the losing side of a local conflict or if their hosts suddenly turn on them. A squad-sized cadre from the 1st Battalion, 3rd Brigade RCMC has been seconded to this bootstrap operation to provide security force leadership and logistics. Volunteers are available from both the RCMC and the Oriflammen Marines to round out the platoon-sized security detachment, and these characters are portrayed as Regency Marine template NPCs from TNE page 66. Security slots may also be filled with recently mustered out veterans. Balduri pesonnel and others with High-G environment skills are preferred because of the 1.5 G environment on So Skire. Skills with archaic and melee weapons would be helpful but not necessary. The security force will be armed and armored as light infantry.

Altogether approximately 110 troops and technicians are expected to make up the So Skire Bootstrap Team.

The Selection Process

The PCs will want to interview key NPCs. The referee needs to do two things to prepare for these interviews. First, the referee needs to generate the key NPCs. These include:

- The members of the leadership group that are not played by the PCs.
- The more highly skilled technicians.
- The more senior and highly skilled military advisors.
- The senior members of the security detachment.

Second, the referee needs to secretly generate the NPCs' personalities, their quirks, their hidden flaws (if any), and to play out these personality traits during the interview. This gives the players a "hands on" feel to the campaign and helps make them realize the interviews are important.

The personality of each NPC will be partially generated through the drawing of the cards as outlined in the basic TNE rules. To supplement this, however, the referee should roll 1D20 on the Personality Table and play the NPC during the interview with the resulting personality.

NPC Personality

D20	*Personality*	*D20*	*Personality*
1	Charismatic	11	Reserved
2	Charismatic, Flawed	12	Reserved, Flawed
3	Charming	13	Reserved
4	Charming, Flawed	14	Reserved, Flawed
5	Friendly	15	Closed
6	Friendly, Flawed	16	Closed, Flawed
7	Open	17	Arrogant
8	Open, Flawed	18	Arrogant, Flawed
9	Open	19	Antisocial
10	Open, Flawed	20	Antisocial, flawed

Charismatic: The NPC establishes an instant rapport with the PCs, which the PCs should also experience. The NPC is highly enthusiastic about the bootstrap project.

Charming: The NPC is very friendly and tries to establish common ground with the players through common experiences or contacts they may all know, campaigns they know about, etc.

Friendly: The NPC is very interested in the mission and its goals, and explores ways with the players to achieve these goals.

Open: The NPC has a somewhat extroverted personality and is capable of easily talking and relating with the players. However, he or she is careful to maintain some personal "space."

Reserved: The NPC is somewhat introverted. He or she is business-like and somewhat cool.

Closed: The NPC seems to have a rigid personality and does not talk freely. He or she refuses to discuss personal matters and does not engage in small talk. While the social "temperature" around a reserved NPC is cool, this one is downright chilly. From time to time, this person's mind seems to be on something 1000 kilometers away.

Arrogant: The NPC is smug, superior, and overbearing to the point of being obnoxious. This is particularly common among academics with doctorates.

Antisocial: This is a sarcastic individual that puts down the bootstrap project and expresses open disdain to the players. Such persons may also exhibit antisocial tendencies by dressing poorly, not bathing, and picking their noses. Although they may be geniuses in their fields or quite well-off financially, they look as though they live in a transit station.

If the result includes "flawed," this indicates the character has a secret flaw or background situation in his or her life that may influence his or her reactions at a later critical moment. The referee should roll on the NPC Personality Flaw Table to determine what this is.

PCs with Research or Streetwise skills may be able to successfully investigate the NPC's background and reveal the hidden flaw.

NPC Personality Flaw	
D10	*Personality Flaw*
1	Criminal Record
2	Death
3	Killing
4	Bad Debts
5	Runaway
6	Family Problems
7	Substance Abuse
8	Cowardice
9	Mental Instability
10	Hidden Illness

Many people have had problems in their lives and need a fresh start. The bootstrap operation may be their way of getting one. On the other hand, their flawed backgrounds may lead to trouble. Remember, secretly write down these flaws and don't reveal them to the players unless they discover them on their own as during the interview or through investigation. If they are not discovered, spring them on the players at an unexpected but appropriate time.

Criminal Record: The individual has been convicted and served time for a crime either in civilian or military life. The individual may have actually committed the crime or not, and may have even committed the crime for good reason. The individual may have been given the opportunity to volunteer for the bootstrap operation in order to avoid more prison time. Such an individual could retain criminal tendencies, ranging from compulsive gambling to thievery to killing rages that could manifest themselves sometime later.

Death: Someone close to the NPC, such as a spouse, parent, or child, has died fairly recently. The NPC may be running away from from a sense of guilt, or simply be looking for a new start, but could be distracted by grief or depression at a critical moment.

Killing: The NPC has accidentally or deliberately killed someone. He or she may be given to violent rages, or fall into a remorseful depression.

Bad Debts: The NPC owes a major financial debt such as a gambling or loansharking debt, back taxes, or alimony payments. He or she is joining the bootstrap operation to escape.

Runaway: This individual is running away from a bad situation: a bad marriage, a bad relationship with parents, from criminals, etc.

Family Problems: Similar to the Runaway, this person is trying to escape from a bad relationship. In this case, however, the relationship has been legally terminated and the person simply wants to get away from painful surroundings.

Substance Abuse: The individual has problems with alcohol or drugs. Assuming the individual is able to retain access to an addictive substance, this will have a major impact during a critical moment of the project, such as during negotiations with So Skirans, or during a complex scientific or medical procedure, or during combat.

> The nightmare came again; the woman turning white on the operating table as the beep of the heart monitor slowed and stopped. He awoke and remembered the slip of the scalpel that nicked the aorta, and the resulting red flood. Most of all he remembered the grief and hate in her husband's eyes. For months he escaped by drinking himself into oblivion. The referrals stopped coming and his practice dwindled to nothing. Soon he was borrowing money from friends to survive. One evening, he was drinking away the day in a Startown bar when he heard the new bootstrap expedition was looking for an assistant surgeon. The next morning, he took his thundering hangover downtown and applied. "A new world, a new beginning," he thought. "Maybe I can finally get away from the demons."

Cowardice: The individual will break and run during combat or in other critical life-threatening situations.

Mental Instability: The NPC acts normal most of the time but may act hyperactive and manic, or become depressed and weepy for no apparent reason. In addition, the person cannot handle stress and will break down in a stressful situation. Under extreme stress, this person could totally withdraw into a catatonic state. The individual may be receiving medication. If so, this person may act normal while his or her medication is available but could exhibit symptoms if their medicine is withdrawn.

Hidden Illness: The individual suffers from a hidden, chronic, physical illness. As long as his or her medication is available, the NPC lives normally. However, if the medication is withdrawn, the illness flares up and could become life threatening. An individual with diabetes, epilepsy, or severe asthma would fall under this "flaw." Such a flaw could be discovered by routine physical examinations and deemed acceptable, or this flaw could be successfully concealed by the NPC, or the illness could be unusual and undetectable.

TRANSIT

A month is allowed for interviewing, recruiting, physical screening, assembling supplies, etc. This period is also used for firearms familiarization training for all members of the bootstrap team who do not have at least a skill level of 1 in Slug Weapon or Energy Weapon. All characters without such a skill receive a skill level 0 in Slug Weapon (Pistol), Slug Weapon (Rifle), Energy Weapon (Pistol), or Energy Weapon (Rifle).

At the end of this period, the bootstrap team boards the Group III *Aurora*-class clipper *Immanuel Kant* in orbit around Oriflamme. She is fresh out of the yards following her post-shakedown overhaul. *Kant* is loaded with a full complement of modules so she has jump-2 performance on the way out. Her modules include:

- 400 ton Fuel Module (refining)
- 200 ton Cargo/Cutter Module
- 2x100 ton Mk 1a Quarters Modules
- 100 ton Troop Carrier Module with assault landers
- 50 ton Cargo Module
- 50 ton Planetary Survey Module with skiff

Kant is also carrying her assigned fueler *Skate*, one 50-ton modular cutter with a passenger/cargo module, a fuel scoop module, and two pre-loaded cargo modules; one 30-ton ship's boat, one 10-ton skiff

attached to the planetary survey module, and three Fury assault landers attached to the troop carrier module (see the **Reformation Coalition Equipment Guide** for details on the above *Aurora*-class clippers, *Manta*-class fuel skimmers, modules, and small craft).

Kant is to leave the smaller cargo, quarters, planetary survey, and troop carrier modules in orbit around So Skire along with her small craft (except for *Skate*) so that the bootstrap team can unload their supplies and equipment as needed. The larger cargo/cutter module will be emptied and carried back to Oriflamme, with its contents, including the three cutter modules, left in orbit around So Skire.

Before *Kant* departs, her crew will clip together the stay-behind clipper modules into an orbiting station. This will give the team an orbital base to which they can retreat if the mission goes sour, and quarters for an orbiting quick reaction team (one squad of 13 RC Marines) equipped with the assault landers. The cutter will use her fuel skimming module to scoop fuel from the inner gas giant for herself, the other small craft, and the self-powered clipper modules. A 2000 square meter, 1 MW solar array is attached to the cargo module to provide power.

Kant's cruise will cover the route Helios, L'steich (where she will rendezvous with *Trigger*), Sand, and So Skire. Returning she will jump directly to L'steich, refuel, and jump home to Oriflamme. The outbound leg is expected to last about four weeks.

Kant's sistership *Thunderchild* is expected to call in four to six weeks with additional supplies.

The referee will roll for starship encounters at each system, but *Kant*'s captain has been given strict orders to avoid a fight if possible. After all, the bootstrap operation is a mission with long-term consequences. RCES does not want it aborted in a fight with a pirate.

PLANETFALL

Kant jumps into the So Skire system after four weeks in and out of jump space. She heads to the nearest gas giant where *Skate* scoops fuel to fill herself as well as *Kant*'s 400-ton fuel module. *Kant* and *Trigger* head inward, constantly looking for other vessels. Note that So Skire is only two parsecs from the class D starport on Targa and three parsecs from the class D starport and Hiver temporary staging base on Barlow. Therefore, encounters with outside human or Hiver starships are small but real possibilities (see the **Reformation Coalition Equipment Guide** for data on Hiver starships). Also, if small craft are encountered, this is an indication of some outside activity at So Skire, the only habitable planet in the system.

Once at So Skire, *Kant* assumes a standard parking orbit and prepares to land the bootstrap team leaders. On the way in, *Kant* dispatches a small craft to place a communications satellite in geosynchronous orbit around So Skire. The team is to land at Gotland, the largest of the three Dawn Isles and the seat of government for Holmgren, Lord of the Isles, nominally allied with the Reformation Coalition. The nearest thing Gotland has to a starport is a broad beach on a protected bay near the fishing village of Sudhaven. Spacecraft can either make a water landing and taxi to a pier built out into the bay, or land on the beach. The only other available clear areas are cultivated. Setting a 50-ton cutter down on a soon-to-be-harvested corn crop would be looked upon with dismay by the locals.

Holmgren was contacted more than a year ago by a covert RCES survey mission during the first exploration of So Skire. The RCES determined that he had the most stable popular support of any leader on the planet and that his driving interest was improving the life of his people. The Dawn Isles was judged to be the wealthiest nation on So Skire and the nation most likely to advance technologically. And, Holmgren was judged to be the leader most open to off-world contact and development in his nation.

The second survey of So Skire, a more ambitious and open mission, confirmed these findings and received permission from Holmgren for the bootstrap mission. The second survey team reported that Holmgren was eagerly looking forward to the bootstrap team believing them to be strong allies against his principal political enemy Rudolph the Bald, ruler of the Woden Empire.

The arrangement left with Holmgren is that the "star people" will return within a year and will pass over his capital at Kongsholm to announce their return to him with the characteristic double sonic boom of a spacecraft entering the atmosphere. Upon receiving the signal, Holmgren will hasten to meet them at the beach "starport."

Thunder on a Clear Day

With the crew in the planetary survey module keeping careful watch of the weather at the landing site (see page 23 of the Survey chapter for weather procedures), the team leaders may begin planning for their arrival. Bad weather can clearly complicate flight and unloading tasks, so the characters will be well advised to not ignore these details.

On approach to the landing beach, they can make a high altitude pass over Kongsholm, capital of the Dawn Isles on the west coast of Gotland to let Holmgren know they have arrived. If this is a high-level campaign, the player characters are the team leaders in this first encounter; if it is a low-level campaign, the PCs are members of the security force.

The very first encounter upon landing that the bootstrap team has with the locals will set to tone for the entire campaign. While Holmgren will be on his way, having heard the pre-arranged signal, there is no way for the bootstrap team to control who will be waiting for them on the beach. Will they be met by Holmgren's retainers, stationed here to await their arrival? Will the political situation have changed since the survey, with Holmgren overthrown and hostile troops waiting to ambush the bootstrap team? Perhaps there was some confusion about the proposed landing site, and they will land amid frightened, possibly xenophobic peasants who have no idea what is happening.

Holmgren has no radio. There is no way to find the answer to these questions without simply landing and finding out what will happen.

Roll 2D6 on the table to the right to determine the nature of the crowd which gathers at the landing site upon the Bootstrap team's arrival.

2D6	First Encounter
2	Nobles
3	Troops
4	Fishermen
5	Townspeople
6	Peasants
7	Peasants
8	Fishermen
9	Townspeople
10	Police
11	Troops
12	Mounted Troops

Nobles: The local Duke of Sudhaven and his retinue of 1D6 members of his household and 3D6 members of his household troops are on the beach waiting to greet the bootstrap team. They had been told by Holmgren to expect the team's arrival and they hurried to the landing site as soon as they saw the launch on approach.

Troops: Troops numbering 3D6 armed with spears and swords are drawn up in formation on the beach. Their commanding officer walks out to greet the team as they emerge from the launch.

Fishermen: 2D6 fishermen are sitting on and near their boats which are drawn up on the beach and were repairing their nets when the bootstrap team landed.

Townspeople: 4D6 curious townspeople from the nearby community of Sudhaven are standing on the beach as the bootstrap team lands.

Police: 1D6 members of the town watch are on the beach. They are

armed with thick staves that function as clubs. One is armed with a sword.

Mounted Troops: A cavalry detachment mounted on horseback armed with swords, lances, and composite bows ride on to the beach as the launch lands.

First Contact Interaction

Whenever groups of people meet for the first time, there are innumerable potentials for misunderstanding, and the fallout of such errors can have far-reaching effects. Such important moments should be roleplayed, allowing the players to experience the uncertainty guessing how best to respond to strange gestures or behaviors on the part of their counterparts. Are they drawing their weapons in honorary salute, or in preparation to attack? Should we draw ours to be safe, or will that frighten them?

These intangibles are the most dangerous when leaders cannot be present to attempt to maintain control of the proceedings, and to exert their leadership over potentially unsteady NPCs. This procedure may be used in any case when unfamiliar groups meet for the first time, such as here in the bootstrap campaign, but also in response to the "Native Encounter" random events result in the colony adventure (Chapter 7).

First, the referee rolls for the friendly team attitude on the table to the right. The result is the basic mental state of the team NPCs as they leave the launch. If PC leaders are present, one of these may attempt an Average: Leadership task to modify the team's attitude. Success indicates the result may be moved one level in any direction, Outstanding success allows two levels. (If Leadership assets are not possessed, Persuasion may be used, but the task becomes Difficult.)

1D6	*Team Attitude*
1	Hostile
2	Fearful
3	Wary
4	Relaxed
5	Open
6	Friendly

DMs on Team Attitude table: –1 if encounter is with troops; +1 if with civilians, +2 if with leaders (such as the local nobles on the table above). Apply a centering DM based on troop quality. A centering DM is one which works to bring the result to the center of the table: a result of 3 or 4. If the result is 4-6, the DM is used as a –DM. If the result is 1-3, the DM is used as a +DM. However, these +DMs will never raise the result to greater than four, and the –DMs will never lower the result to less than 3. Novice: no DM, Experienced: ±1, Veteran: ±2, Elite: ±3.

The local people who see the team on the beach will be able to sense their attitudes from the team's facial expressions, body language, and other non-verbal clues. This affects their own attitude to the team.

The leader of the friendly team must now attempt an Average Liaison Task to assure the locals' cooperation and positive attitude (if no Liaison skill, use Persuasion or Leadership, but difficulty level becomes Difficult). In the current example this would be a PC, or else Kaminski if the PCs are merely playing security troops. In the case of a random encounter between, say hunters and a local war party (in the case of the colony adventure), the referee must determine the talents of the group, but in most cases this will result in the use of the unskilled penalty (**TNE** page 108), and the outcome of the situation will be dicey.

Index the result of the task with the table to the right, modified by the attitude of the friendly party obtained above.

The reaction is modified by the team's attitude: +2 if Friendly, +1 if Open, –1 row if Wary or Fearful, –2 rows if Hostile. As an example, if the Liaison task is a success and the team is Friendly, go up two rows on the table to +1, Actively Cooperative. If the task is a failure and the team is hostile, the locals will be hostile and frightened and will flee and/or attack. (Because of the complexity of interpersonal and political relations, further developments after this initial contact are at the referee's discretion or according to scenario instructions, for example, immediately below.)

If the encounter goes smoothly, the locals will wait in place until Holmgren arrives, at which time they are escorted to Holmgren's palace in Kongsholm. How and where the meeting takes place is the referee's choice. If the team travels to Kongsholm, they should use local transportation to blend in and get the feel of Gotland and the Dawn Isles. The journey to Kongsholm would be a great opportunity for encounters and side adventures.

If the encounter goes badly, the team may have to retreat back to the ship. In that case, another attempt will have to be made to contact Holmgren, such as a covert mission to Kongsholm.

Meeting Holmgren

The leaders need to meet with Holmgren. His reaction will determine if the team is welcome in his nation or not. His reaction will be determined by another Liaison task as described above in First Contact Interaction. However, the result is modified by the final reaction of Holmgren's own people, and not the attitude of the bootstrap team.

HOLMGREN'S INITIAL REACTION

Task Result	*Reaction and Initial Level on Political Track*
+2	Totally Cooperative, Eagerly Welcomes Team. Level 2.
+1	Actively Cooperative, Friendly, appears to welcome team. Level 3.
Outstanding Success	Passively Cooperative, outwordly friendly, curious about team. Level 4.
Success	Neutral, cool and indifferent. Level 5.
Failure	Passively Uncooperative, seems agitated, worried, uncertain about team. Level 6.
Catastrophic Failure	Actively Uncooperative, seems very agitated, orders team back to ship. Level 7.
-1	Hostile, arrests team. Level 8.

Modifiers: +2 rows if local nobles eagerly welcomed team, +1 if local peasants or townspeople eagerly welcomed team or if nobles were friendly, -1 row if peasants/townspeople were uncooperative, -2 if nobles were uncooperative.

If the result is negative and unless the team is thrown in jail, they may attempt to win over Holmgren again 24 hours later with a Formidable test of Persuasion. If they are jailed, they will have to attempt to escape.

The notation of "Level" shows the initial position on the Political Track that corresponds to the result. See "Dealing with Holmgren," on the next page.

FIRST CONTACT REACTIONS

Task Result	*Reaction*
+2	Totally Cooperative, Eagerly Welcomes party.
+1	Actively Cooperative, Friendly, appears to welcome party.
Outstanding Success	Passively Cooperative, outwordly friendly, curious.
Success	Neutral, cool and indifferent.
Failure	Passively Uncooperative, seem agitated, worried.
Catastrophic Failure	Actively Uncooperative, seems very agitated, afraid; if troops may attack.
-1	Hostile and Frightened, if civilians will flee; if troops, will attack.

Holmgren, Lord of the Isles

Elite NPC

Combat Assets: Armed Martial Arts (Large Blade), Unarmed Martial Arts

Other Assets: Leadership 14, Persuasion 12, Bargain 10, Ground Tactics 10, Liaison 9, Streetwise 9, Willpower 9, Riding 9, History 8

Motivation:

Spade Ace: Holmgren is a charismatic and highly popular leader. He radiates charm in close company, and inspires all who hear him speak publicly. Holmgren is responsible for building his country's navy as a deterrent to aggressors from the mainland, and for improving the Dawn Isles' economy through shrewd trade pacts with other nations, particularly the Borean Enclave and the Aylward Islands.

Heart King: Holmgren is popular because he is honorable. He keeps his promises to his people by never promising what he cannot accomplish. His first act upon ascending to the throne was to fire the nation's corrupt tax collectors and appoint honest officials in their place.

Personality: Holmgren is genuinely interested in cooperating with the RC and the bootstrap team, but does have serious reservations the way that this should be done.

He will not stand for the RC coming in and doing everything for him, protecting him, defeating his enemies, and building new equipment that his people will not understand. This will not ultimately help his people; it will only make them dependent on outside protection, and will not allow them to help themselves. What is more, this will undermine Holmgren's political position with the Council of Nobles, who will see him as an impotent puppet of the off-worlders and will withdraw their support from him, invalidating his position as Lord of the Isles.

While he is open to and even eager for the benefits promised by the RC, he will irritate the PC leaders by insisting on knowing all of the details of every proposed action, and periodically make small, even cosmetic changes, just to prove that he is in control of the process. However, such cosmetic changes are important, as they will prove to the Council that the changes are under Holmgren's control, and that he must receive credit for them. The bootstrap team ignores these considerations at their peril, for if Holmgren loses power, there is no telling what his replacement will be like, and the ramifications for the unity of the Dawn Isles.

In these meetings, Holmgren will be fond of wagging his finger at the bootstrap team leaders and saying, "If you *give* a man a fish, he will eat for a day; if you *teach* a man to fish, he will eat for a lifetime."

While this remark gives insight into Holmgren's concerns, this is perhaps less important than the fact that it is true.

THE MISSION

Once contact is successfully made, the team and its equipment are brought down from orbit. They must establish a base camp and then set up plans for dispatching action teams throughout the Dawn Isles. Meanwhile in orbit, *Immanuel Kant* prepares to depart and puts together the orbiting station.

After the base camp is established, action teams fan out to sites where assistance is needed, as determined by the PCs and negotiated with Holmgren.

Dealing with Holmgren

As discussed in the Holmgren sidebar, Holmgren's success as Lord of the Isles depends on his walking the fine line between gaining the benefits of interstellar contact for his people without appearing to be too dependent upon them. While the Dawn Isles' Council of Nobles is not a particularly noxious pit of vipers as such bodies go, it is nevertheless full of ambitious leaders who will not miss a chance to see to their own power if Holmgren is squandering his own legitimacy.

Assisting Holmgren in walking this line is also part of the bootstrap team's job, as if he goes down in flames, their mission, in all likelihood, will as well.

All of this Byzantine and Machiavellian maneuvering is simulated by the use of a monthly die roll on a Politcal Table which drives the political position marked on a Political Track.

This is a modification of the political table and track presented in Chapter 4. In this bootstrap adventure, this political track combines the effects of two separate but related dynamics: 1) Holmgren's relationship with, and confidence in, the bootstrap team, and 2) Holmgren's power in, and support from the Council of Nobles as Holmgren's policies become more and more associated with those of the RC bootstrap team.

This means that each level on the Political Track has a dual function. First, it shows how willing Holmgren is to authorize further bootstrap activities. The higher the level, the happier he is with the team and their efforts, and the more willing he is to go along with more development.

Second, it shows how strong or precarious Holmgren's position is as Lord of the Isles. The higher the level, the stronger the bootstrap team has made his hold on power. The lower the level, the more the bootstrap team has botched their job, either by making Holmgren look like a fool for countenancing the efforts of bungling aliens, or by undermining Holmgren's power by making him look like a hollow, ineffectual puppet under the thrall of his "court magicians." Naturally it is this second function that explains Holmgren's willingness to further cooperate with the bootstrap team: their success in dealing with him goes hand in hand with their success in making Holmgren look good to his people and his power-hungry nobles.

Note that at the very beginning of the campaign, the political track only shows Holmgren's relationship with the bootstrap team, and has nothing whatever to do with his hold on power. It obtains both functions and retains them for the remainder of the campaign once the following two conditions are met.

1) The bootstrap team's relations with Holmgren on the political track rises to Level 3: Good, and

2) While the position is at Level 3, Holmgren agrees to allow at least one development operation, as explained in the "Lobbying for Permission" section which follows immediately.

Lobbying for Permission: Each month the bootstrap team leaders must present their requests for the upcoming team's operations. In general terms, the number of possible operations is one per A Team, based on the location of that team (i.e., if the A Team is assigned to train a military unit, the team must spend that month in the location where that unit resides, if the A Team is assigned to help the local miners, they must spend the month located where mining is taking place, etc.), four operations for the Base Team (again,

assuming that portions of their personnel are moved to the required location, or else that the persons being trained are brought to the base camp), and two operations for the command group (i.e., the PCs if they are the team leaders, with the same geographic caveat as discussed for the Base Team above). Thus the maximum total operations, and thus task rolls, per month is 14.

The details of these development operations tasks are described in "The Jobs" section on pages 59-60 below.

Each task desired by the bootstrap leaders requires a Persuasion roll. The difficulty level of this roll is shown on the Political Track, and is therefore based on the current level of these relations. Success indicates that Holmgren has granted permission for the indicated development task to be conducted during the current month. Failure and Catastrophic Failure both indicate that permission was denied.

PC bootstrap leaders should note that they may attempt these development tasks even if Holmgren denied permission, however, if these tasks fail, the –DMs on the political roll are *doubled.*

Bootstrap personnel who have had their operations for month cancelled may not be reallocated for other tasks that month.

If the request was approved, the group is transported to its required location and makes the indicated task roll. Success not only indicates that the team succeeded at its task (helping the locals to improve their agricultural, raw materials productivity, improved the training of local troops, etc.), but also succeeded in the altogether more ticklish aspect of handling the task so that it made Holmgren look good, and not just the bootstrap team. Failure can be either a failure to accomplish the basic task, or a successful task which somehow ended up making Holmgren look bad, ineffectual, weak, or somehow not in control of the bootstrap activities.

The Political Table: The political roll is made once per month, after the task rolls for all development tasks and random events for the turn have been made, as all of these items provide potential DMs for use on the table.

The Output roll DMs shown on the table are only used if the Economic Model is in use (see page 64 for details).

POLITICAL TABLE

D20	*Result and Output DMs*	*Track Movement*
–5	Dissolved, –5	Down 2 levels
–4	Coup Attempt, –4	Down 2 levels
–3	Censure, Assassination, –3	Down 1 level
–2	Caution, –3	Down 1 level
–1	Secession Threat, –2	Down 1 level
0	Secession Threat, –2	Down 1 level
1	Nobles Uncertain, –1	—
2	Nobles Uncertain, –1	—
3-18	No Effect	—
19	+1 DM, one random sector	—
20	+1 DM, one random sector	—
21	+1 DM, one random sector	Up 1 level
22	+1 DM, all sectors	Up 1 level
23	+1 DM, all sectors	Up 1 level
24	+1 DM, all sectors	Up 1 level
25	+2 DM, all sectors	Up 2 levels
26	+2 DM, all sectors	Up 2 levels

Nobles Uncertain: Small numbers of nobles express concern about the dangerous reliance on unreliable off-world support. –DM shown applies to only one sector (1-2: agriculture, 3-4: materials, 5-6: industrial)

Secession Threat: Small numbers of nobles begin to discuss the possibility of seceding from the Council along with their fiefs if the unacceptable reliance on off-world methods continues. –DM shown applies to only one sector.

Caution: Council of Nobles formally votes a Message of Caution to Holmgren, officially voicing their opposition to any further reliance on the off-worlders. –DM shown applies to materials and industrial only, not agriculture.

Censure, Assassination: Council of Nobles issues a Note of Censure to Holmgren, a stronger message than the Caution, above. As controversy continues to mount, small, disorganized group or individual attempts to kill Holmgren. If assassination is successful, Holmgren's replacement will order the bootstrap team out of the Dawn Isles on threat of death. Referee's discretion, low-level roleplay is recommended. –DM applies to all sectors.

Coup Attempt: Organized group of Nobles attempts to take over government from Holmgren. If successful, will place Bootstrap team under arrest. Referee's discretion, low-level roleplay is recommended. –DM applies to all sectors.

Dissolved: The Council votes to dissolve the position of Lord of the Isles, throwing Holmgren into jail to be tried for treason. The bootstrap team will be placed under arrest for eventual execution. Referee's discretion; if you don't start some low-level roleplaying now, you have to ask yourself what the heck you think you're doing playing this game, anyway. –DM applies to all sectors.

POLITICAL TRACK

Level	*DM*	*Diff Level*
Level 1: Excellent	+3	Easy
Level 2: Very Good	+2	Average
Level 3: Good	+1	Average
Level 4: Fair	—	Difficult
Level 5: Marginal	—	Formidable
Level 6: Poor	–1	Formidable
Level 7: Bad	–2	Impossible
Level 8: Terrible	–3	may not be attempted

DM: Die modifier applied to roll on Political Table on turns when that political level is in effect.

Diff Level: Difficulty level for Persuasion rolls when attempting to persuade Holmgren to allow development operations.

RCES SCOUTING REPORT

So Skire System

So Skire Subsector/Old Expanses 1732

Star System
Sector: Old Expanses
Subsector: 1732/So Skire
Star Type: M0V
Planetoid Belts: 0
Gas Giants: 4

Main World
Starport: X
Pre-Collapse Starport: E
Diameter: 9360 kilometers
Atmosphere: Standard
Hydrosphere: 71 percent

NOTES

So Skire has been a stable backwater world unaffected by Virus and the Collapse because of its low pre-Collapse tech level. Normally, it would not draw much attention. However, a recent survey by a free-lance team found significant heavy metal mineral deposits on this dense, high gravity world and a relatively friendly native population near the survey site. Coupled with its position on the spinward edge of a dense cluster of worlds leading toward Hiver space, this makes So Skire worthy of intensive contact and bootstrap operations. With proper and timely development, So Skire could become a major source of vital minerals for the Reformation Coalition and a friendly "bridge" world between the Coalition and Hiver space.

Physical

So Skire occupys Orbit 0 around its M0V primary "Mymr." So Skire orbits toward the outer edge of the habitable zone (Orbital Factor 800). This, and its primary's relatively low luminosity result in cool temperatures on the planet's surface. Orbits 1 and 2 are empty, orbits 3, 4, 5, and 6 contain the system's four gas giants.

So Skire has a small (size S) rocky moonlet orbiting at 85,140 kilometers (9 diameters) and a ring system at 18,920 kilometers (2 diameters).

So Skire is classified as a habitable world but it's no paradise. It has a base surface temperature of 4°C and temperatures ranging from +29°C to -76°C. So Skire's temperate zone extend from 24° north to 24° south of the equator (three hex rows on standard global data view maps). Latitudes north and south of this line experience severe seasonal freezing or permanent glaciation. Weather factors for So Skire total 0.

It is an old world. Much of its original atmosphere has leaked away into space in spite of its 1.55G surface gravity. So Skire's atmosphere has a pressure of 0.9 atmospheres and a 20 percent oxygen concentration making it breathable without assistance. The axial tilt is 26 degrees giving the world pronounced seasons. So Skire's day is 24 hours long, and its year is rather short at 47 standard (and local) days, which is fortunate, given the severity of its winters.

Oceans cover 71 percent of the planet. Land masses consist of one major continent, three minor continents, seven major islands, and five archipelagoes.

The "freeze lines" on So Skire (three hex rows each side of the equator) marks the beginning of "the barrens," a land region that freezes every winter. The barrens are made up of rugged badlands with some glacier tongues extending from the ice cap. Vegetation is limited to lichens and other small growth, somewhat analogous to the Terran permafrost region. The "tropics," between the north and south freeze lines, do not freeze during the winter, except for some localized temporary freezing during the winter nights of hex row 3. The polar caps begin eight hex rows north and south of the equator. These are permanently frozen regions covered with a kilometers thick layer of ice.

The oceans poleward of the freeze lines experiences intermittent freezing depending on the latitude and season. During the summer and fall, ice floes and 'bergs calving off the polar caps are frequently encountered above the freeze line. Increasingly dense surface ice with pressure ridging forms during the winter and spring seasons.

The northern half of the major continent is ice-locked as are two of the three minor continents and most of the third. Most islands and archipelagoes are in temperate waters, however, and the human habitation is naturally concentrated here.

The Drakensberg mountain range which follows the west coast of Woden, the major continent, lie along the Draken fault line. These mountains experience major seismic and volcanic activity, and continuing geological uplift as the Western Marine tectonic plate perpetually rides up and over the Woden plate. Seismic activity along fault lines throughout the planet is frequent, thanks to tidal stresses caused by So Skire's proximity to its primary. The Spires of So Skire, five volcanoes towering more than 5000 meters above Cape Titan were tourist attractions during the Last Imperium. The few visiting sportspersons and tourists that traveled "off the beaten path" contributed a significant share of the planet's off-world income visiting the Spires and climbing nearby peaks during this period. Other income came from the occassional trader and from research teams studying the world's unusually primitive civilization.

Another source of income was a rare algae that only grows on the surface of tiny mountain lakes among the Spires of So Skire. The sulfur and other elements in the volcanic discharge made the algae and the microrganisms it hosts unique producers of wide-spectrum antibiotics. This was a primary export of the world during the Rule of Man and early in the Last Imperium. However, this pharmaceutical was later synthesized and reproduced in vast quantities in high tech pharmaceutical plants and the market for So Skire's product dried up.

Now that these mass production methods were lost in the Collapse, this algae may become a valuable export to the nearby Coalition worlds.

The Asgard Strait separating the major continent from Frig, the continent immediately south, is frozen solid about 16 days out of the year. The Strait is the major marine traffic route between the Aylward Islands in the Western Sea and the states on the eastern coast of Woden.

Other continents include Loki northwest of Woden, and Ragnar south of the Aylward Islands. Except for the extreme northern tip of Ragnar, both are uninhabited.

Other major inhabited regions include the Aland, Gotland, and Bjornholm Islands, know collectively as the Dawn Isles, east of Woden.

History

So Skire was settled during the rapid expansion of the Empire of Man following the defeat of the Vilani in the Interstellar Wars. Early records are few, indicating it was settled as a mining colony by colonists of Terran descent. It was abandoned during the Long Night and the technology level of its surviving inhabitants crashed to TL 0. Their technology had climbed to TL 1 when they were rediscovered about 560 by Last Imperium scouts. By then, other resource worlds closer to the Imperial core had been developed and So Skire was noted in IISS journals and bypassed. Harsh agricultural growing conditions and the lack of native technology combined to keep the planet's population at around 100 million. The IISS and later the Solomani Confederation Navy had provided and maintained communications technology which helped So Skire's people remain united and govern themselves as a representative democracy. Otherwise, the IISS declined to "interfere" with the local society although it did allow trade and contact with off-worlders under supervision of personnel from the Scout base at Keghe (1733). With the Collapse, however, the communications satellites and ground-based networks failed, the base at Keghe disappeared, and the world became balkanized.

Techno-Politico-Military

So Skire's technology level is the equivalent of Terra's circa 1200-1300 AD. Iron is the predominent metal, used for weapons, plate armor, nails and other fasteners, wagon wheels, and utensils. Homes and other buildings are sturdily build of wood and stone to resist the high winds and cold temperatures. The indigenous population wear homespun cloth and leathers and furs taken from local animals. Agricultural production is primitive, using plows drawn by Terran-descended domesticated musk oxen and local equivalent animals for cultivation, and hand implements for harvesting. Local plant life is edible but must be supplemented with Terran-descended plants in the diet ,or with vitamins.

Transportation consists of riding animals, usually Terran-descended horses and mules, and wagons drawn by mules, horses, or musk oxen over rough roads on land, or by river barges. Sea transportation is by sailing ships and sail and oar-powered coastal galleys.

Aside from the recent contact by the RCES-sponsored survey team, there has been no known off-world contact since the Collapse. The survey team discovered the world's population is divided among eight nations scattered across the face of So Skire. They include:

1. Dawn Isles: Ruled by the Lord of the Isles, a benevolent feudal monarch supported by his people, the Dawn Isles is the most prosperous of the So Skire nations. It includes Aaland to the north, Gotland in the center, and Bjornholm in the south. The survey team's landing site was at the south coast of Gotland, virtually on the equator. Gotland has some of the richest farmlands and highest crop yields on the planet. It also has a proven supply of sulfur enabling it to begin producing crude gunpowder, making it the equal of any rival powers. Its people seem the most open to off-world contact and influence. Gotland has therefore been chosen as the prime base site and initial objective of the bootstrap team.

2. South Dawn: An archipelago running between Bjornholm and the barren island Bifrost in the south, South Dawn is also a monarchy ruled by a nephew of the Lord of the Isles and is closely allied with its neighbor to the north.

3. Borean Enclave: A small nation in the northernmost habitable portion of the Woden Continent, the enclave is ruled by a representative democracy. It is an active trading partner with the Dawn Isles, and its only mainland ally. The Boreans trade mainland timber for Dawn Island farm products and manufactured goods.

4. Svensholm: A small coastal nation existing primarily from fishing the rich shallow banks offshore in the Crimson Sea. Svensholm is allied to and partially occupied by the Woden Empire to the south. There is an active resistance to the Wodenites supported by both the Boreans and the Dawn Isles.

5. Woden Empire: The Woden Empire is rich in timber resources, possessing the largest harvestable forests in the settled areas of So Skire. It is ruled by Rudolph the Bald, who believes he is destined to reunite So Skire under his crown. Rudolph is an absolute monarch whose word is life and death. He is supported by his wealthy nobility and, surprisingly, by his impoverished population, seduced by the promise of a better life when The Empire rules all of So Skire. The Empire's crop land is poor and has difficulty supporting its population. Timber is grudgingly traded with the Dawn Isles for their farm products and manufactured goods.The Dawn Isles' rich farmland is a priority target for inclusion in the Empire. So is the integration of Svensholm, the Borean Enclave and their fishing fleets. However, the Dawn Isles' powerful navy has thwarted these plans so far.

6. The Southern Republic: The Southern Republic control So Skire's major maritime trade route through the Asgard Straits. The Republic is ruled by the Brotherhood, a mystical band that believes some day the starmen will return with their marvelous speaking boxes and help them reunite So Skire. The Republic charges merchant vessels tolls for the privilege of passing through their waters and the Straits. So Skire's maritime nations would like to end this practice but have not mustered enough power to break the Republic's hold on the Straits.

7. Aylward: Aylward includes North and South Aylward Islands and is ruled by a representative democracy. The islands are rich in precious metal deposits which are sources of trade goods to be exchanged for manufactured products from the Empire and the Dawn Isles. A "White Fleet" sails eastward each spring blown by the prevailing winds from the west. After passing through the Straits and paying its tolls, the fleet calls at ports in the Empire and the Dawn Isles. Here precious metals and jewelry are exchanged for iron nails, wire, fasteners, wagon and ship fittings, and other manufactured products. The fleet then continues eastward, eventually arriving home after a voyage around the world.

8. The Polity of Ragnar: Despite its impressive sounding name, the Polity is little more than a council of tribal chiefs who rule the wild clans of Ragnar. Ragnar has the lowest tech level on the planet, effectively TL-0. Any TL-1 artifacts are acquired through theft and piracy. Their chief activity is raiding the Aylward Islands and the White Fleets as they depart and arrive home. The Aylwarders may eventually tire of this, and take Ragnar under their control.

So Skire's estimated current population broken down by nation is shown at right:

Nation	*Population*
Woden Empire	30,000,000
Dawn Isles	20,000,000
Southern Republic	15,000,000
Aylward Islands	10,000,000
Borean Enclave	8,000,000
Svensholm	11000000
South Dawn	5,500,000
Ragnar	500,000
Total	100,000,000

The Jobs

The basic bootstrap Action Team (or "A Team" for short) of which there are eight on this mission, includes five personnel: a military advisor, an agronomist, a civil engineer, a medic and a security/commo specialist. All are armed with light weapons. Meanwhile, the Base or "B Team" at base camp includes specialists such as geologists, teachers, intelligence gatherers and analysts, security force members, and the air raft pilots. They are available for dispatch on special missions where their expertise is useful.

These are the jobs of the bootstrap specialists and the situations in which they work. If the PCs are low level characters, you can place them in one of these situations if they have the necessary skills, and have them roleplay with the local people on a day to day basis. If you are running a high level campaign, you can have the players travel from site to site and use "walk-around management" techniques to become personally involved. You can use these settings as starting points for "mini-campaigns" within the main campaign. Meanwhile, the main campaign will progress from month to month at high level with events that will positively or negatively impact the players. These events are described beginning on page 64.

Leaders: These are the players in a high level campaign, or they can be distant figures that occasionally appear to players in a low level campaign. Leaders have two basic jobs. First, they are diplomats, constantly working with Holmgren and his advisors to advance the work of the bootstrap team. Second, they plan and supervise the operations of their subordinate A and B Teams, seeing that their capabilities are used to the best possible effect. From time to time, these leaders will also appear personally to lend their skills or guidance to the low-level efforts of these teams. As always, leaders must also respond to and cope with events or emergencies that crop up and impact the mission.

Military Advisors: They work directly with key units of the Dawn Isles armed forces, training them in new tactics and methods of operations. Although there are no active hostilities as the team moves into place, there is always the chance of raids from the mainland. And, Holmgren might want advisors to accompany his troops on a raid against the Woden Empire.

A military advisor may attempt to raise the troop quality of a battalion by rolling a Formidable Instruction task. Six consecutive success results mean that the battalion being trained has risen one experience level. This higher level must be maintained by continuing to roll consecutive successes at a Difficult Instruction task each subsequent month. Only one quality level may be obtained this way, and this new level must be less than the experience level of the NPC instructor. For example, a Veteran military advisor could raise a Novice battalion to Experienced, but could not raise an Experienced battalion to Veteran.

Each monthly success on this roll adds +1 to the Political Roll, +2 if Outstanding Success. There is no penalty for basic failure, but Catastrophic Failure incurs a –1 DM on the Political Roll.

One military advisor is in each A Team, and the entire A Team must participate in this activity for the entire month, and may not conduct other development tasks during this time.

Geologists: They are to begin an immediate mineral survey of the three planetary hexes of the northernmost Dawn Isles (Aaland and Gotland). The data they can determine for the three hexes is found on page 48. After the Dawn Isles have been thoroughly surveyed, geologists may participate in covert survey missions to the mainland to look for useful mineral finds there.

A geologist may roll a Formidable Geology task each month to simulate the assistance of local miners in finding and accessing mineral wealth.

Each monthly success on this roll adds +1 to the Raw Materials output roll of the Dawn Isles (if using the economic model) and +1 on the Political Roll, or +2 on each roll if Outstanding Success. There is no penalty for basic failure, but Catastrophic Failure incurs a –1 DM on the Political Roll.

Geologists are part of the Base Team, and any such Geological tasks come under the maximum of four tasks per Base Team per month, but see also page 64 for survey requirements.

Agronomists: In many ways these specialists in farming science are the keys to the mission's success. They will probably be more intensely involved with the local civilian population than any other team members, except possibly the medics. They will visit farming villages near the A team camps and introduce new farming methods such as contour farming on hillsides and new implements such as an improved iron plow that should help increase crop yields and the income enjoyed by local farmers. At least one biologist who is an expert in fisheries is included among the agronomists and is assigned to improve the catch at one or more fishing villages.

An agronomist may roll a Formidable Farming and Instruction (i.e., lower of the two assets) task each month to simulate the assistance of local farmers in using advanced farming techniques to increase their yields.

Each monthly success on this roll adds +1 to the Agricultural output roll of the Dawn Isles (if using the economic model) and +1 on the Political Roll, or +2 on each roll if Outstanding Success. There is no penalty for basic failure, but Catastrophic Failure incurs a –1 DM on the Political Roll.

One agronomist is in each A Team, and the entire A Team must participate in this activity for the entire month, and may not conduct other development tasks during this time.

Civil Engineers: They also work with the local civilian population advising them how to build and improve roads, bridges, aqueducts, sewer systems and other public works to improve transportation and sanitation in the country. Civil engineers will also assist in the design and construction of public buildings as well as teach local farmers and townspeople improved architectural and construction methods.

A civil engineer may roll a Formidable Construction and Instruction (i.e., lower of the two assets) task each month to simulate the assistance of the local populace in improving their infrastructure.

Each monthly success on this roll adds +1 to the Industrial output roll of the Dawn Isles (if using the economic model) and +1 on the Political Roll, or +2 on each roll if Outstanding Success. There is no penalty for basic failure, but Catastrophic Failure incurs a –1 DM on the Political Roll.

One civil engineer is in each A Team, and the entire A Team must participate in this activity for the entire month, and may not conduct other development tasks during this time.

Metallurgists: Their job is to teach local metalworkers such as blacksmiths and smelters to make the best use of local metal deposits. Where the geologists find minerals such as nickel that can be used to make improved iron alloys, the metallurgist will teach the locals how to make and use the alloys. Improved farm implements, household goods, industrial products, and weapons all result from the metallurgists' work.

A metallurgist may roll a Formidable Metallurgy and Instruction (i.e., lower of the two assets) task each month to simulate the assistance of local craftsmen in improving their techniques and output.

Each monthly success on this roll adds +1 to the Industrial output roll of the Dawn Isles (if using the economic model) and +1 on the Political Roll, or +2 on each roll if Outstanding Success. There is no penalty for basic failure, but Catastrophic Failure incurs a –1 DM on the Political Roll.

Metallurgists are part of the Base Team, and any such Metallurgy tasks come under the maximum of four tasks per Base Team per month.

Doctors/Medics: A key element of the "Hearts and Minds" program, the A Team medic makes the rounds of villages near the A Team base taking care of wounds and diseases, and teaching local people basic medical skills and sanitation. The doctors back at the B Team headquarters not only take care of the bootstrap team members, they also are on call to assist the field medics with difficult cases especially when they affect important local individuals, such as the child of a village headman or a member of the nobility. One of the doctors is a veterinarian offering veterinary medical advice to livestock farmers.

Medical personnel are available to respond to medical requirements on the random events table, but also to conduct beneficial tasks each month.

A doctor/medic may roll a Formidable Medical (Diagnosis) task each month to simulate the treatment of the local populace in minor illnesses as well as administering innoculations against local diseases. This process increases the overall health and therefore productivity of the population.

Each monthly success on this roll adds +1 to all output rolls of the Dawn Isles (if using the economic model) and +1 on the Political Roll, or +2 on each roll if Outstanding Success. There is no penalty for basic failure, but Catastrophic Failure incurs a –1 DM on the Political Roll.

One medic is in each A Team, and the entire A Team must participate in this activity for the entire month, and may not conduct other development tasks during this time.

Doctors are part of the Base Team, and any such Medical tasks come under the maximum of four tasks per Base Team per month.

Teachers: The teachers have a "knowledge transfer" mission. They are to set up an academy for the brightest local inhabitants and teach them basic science, math, and language skills to foster improved communcation with the bootstrap team. They also teach the locals about the universe, So Skire's place in it, and the history and philosophy of the Reformation Coalition.

A teacher may roll a Formidable Instruction task each month to simulate the progressive education of the local population in basic concepts. By "raising the conciousness" of the society to the advantages of interstellar contact, these tasks have an enlarged influence on the Dawn Isles' political acceptance of interstellar contact.

Each monthly success on this roll adds +2 on the Political Roll, or +4 if Outstanding Success is rolled. There is no penalty for basic failure, but Catastrophic Failure incurs a –2 DM on the Political Roll.

Teachers are part of the Base Team, and any such Instruction tasks come under the maximum of four tasks per Base Team per month.

Intelligence Specialists: Based at B Team headquarters, the intelligence specialists are tasked with gathering political, military, and economic intelligence from throughout So Skire. They are also responsible for creating up-to-date, accurate maps of the planet. Orbital photography from the high station supplemented with local surveys are used for map making. As soon as the intel section arrives on planet, they begin setting up a network of informants in the Dawn Isles, and setting up electronic surveillance devices in key locations, including Holmgren's palace (they have brought along a large supply of gold and silver for payments to agents). Members of their section also work with Holmgren's own intelligence service in improving Holmgren's agent networks on the mainland, particularly in the Woden Empire and the Southern Republic.

Once their local agents are in place, the bootstrap intell section will conduct covert missions into the Empire and Republic and set up their own networks in these countries. The B Team intel shack is the most tightly guarded area on the headquarters base. These team members present perhaps the most interesting opportunites for low-level roleplaying that can be generated by the bootstrap campaign, and are an excellent choice for players that want to hire onto the bootstrap mission for low-level roleplaying.

Because of the tremendous diversity of these operations, there are no monthly development tasks that can be rolled, although the intel specialists are the characters that make the intelligence rolls vs. some of the results on the random events table. Rather, intel specialists are best handled by discussion between the referee and players on how they would best like to see them used.

Security Specialists: These are the "grunts" of the operation. This platoon-sized unit is split into three squads. 1st Squad is the quick reaction force aboard the orbital station. It is armed with light battle dress and standard Coalition TL-10 to -12 weapons (See the **Reformation Coalition Equipment Guide**, particularly pages 9-11, 18-19, 52-55, 60-71, 85-87, 93-99, and 106-108 for details on standard Coalition military equipment and weaponry). Its mission is to back up the team on the ground with an assault landing if they get into serious difficulty with the locals. 2nd Squad is the ground security force at the B Team headquarters. It is armed with TL-8 infantry weapons so as to not overly intimidate the local population. Its job is the hold the headquarters area until the team can be evacuated to orbit if the mission goes sour. It also backs up the field security squad. 3rd Squad is the field security squad. It is split with one member attached to each A Team in the field. The trooper doubles as the A Team's commo specialist. His or her primary job is the team bodyguard. The team could not withstand a determined assault, but usually, a firepower demonstration will be enough to calm restless locals. 1st and 2nd squads swap duties once a week.

Security specialists have no development tasks to roll, but are instead involved as body guards in the entire spectrum of such operations. PCs who seek a low-level *entré* into the bootstrap adventure will really get a chance to "see the world" by signing on as security specialists.

Air Raft Pilots: This includes two pilots who double as mechanics. The team has two convertible air rafts each with a capacity of six persons (one pilot and five passengers) and 1.86 tonnes of cargo, and a maximum speed of 630 kph at altitude and 158 kph at NOE. (For more details see the **Reformation Coalition Equipment Guide**, pages 114-115.) The chief job of these pilots is the rapid transportation of bootstrap team members to where they are most needed, such as in response to medical or military emergencies, to meetings with Holmgren, etc. It is no accident that the A Teams are sized to each fit in a single air raft.

So Skire Bootstrap Team Composition

Command Group	7
8 Action Teams	
Military Advisor	8
Agronomist	8
Civil Engineer	8
Medic	8

Orbital Group Subtotal	22 (+9)
Bootstrap Team Total	108 (+9)

*Parentheses indicate crewmembers from *Kant* crew; not included in Bootstrap Team Total.

INTEGRATING PCS AND DETAILED NPCS WITH THE MASS COMBAT SYSTEM

In the event that the campaign requires the armies of Woden and the Dawn Isles to face each other in the field, the influence of the Reformation Coalition military advisors, both PCs and NPCs, will be felt. These clashes will be resolved with either the standard TNE combat system (rarely, only for very small engagements) or, more often, with the mass combat system presented in Chapter 5 of this book. The following modifications are for use with the mass combat system to allow integration of character abilities.

These modifications are based on the assets of the character *in command* of the unit in question. For the purposes of this bootstrap adventure, this is also expanded to include the PC or NPC military advisor to a given unit.

Ground Tactics: If the Ground Tactics *asset* of the character in charge is higher than unit's asset based on NPC quality, use the Ground Tactics asset for all detection rolls.

In addition, when rolling for blocking movement, the Ground Tactics *skill level* is used as a DM on the D20 roll. If the unit itself is attempting to block an enemy unit, the skill is a –DM on the roll. If an enemy unit is attempting to block the unit, the skill is a +DM on the enemy's roll.

When attempting to withdraw before combat, or if an enemy is attempting to withdraw before combat, add the Ground Tactics *skill level* to the unit's movement factor to determine which unit is faster (the enemy unit should have this benefit granted as well).

For purposes of order of fire, the Ground Tactics *assets* of the opposing commanders is used as the final tie breaker to see who fires first.

For fire resolution, use *one half* (round fractions down) of the commander's Ground Tactics *skill level* as a +DM on the fire resolution roll.

Leadership: The Leadership asset is used to avoid adverse moral effects. Whenever a unit reaches its Retreat, Rout, or Surrender level, a PC or detailed NPC leader can make a roll against his or her Leadership asset. Success indicates that the morale effect is disregarded, failure indicates that the morale condition takes effect normally, and Catastrophic Failure indicates that the morale condition becomes one level worse (i.e., Retreat becomes Rout, Rout becomes Surrender, Surrender remains Surrender). Difficulty level is based on the morale level that has been reached: Retreat is Average, Rout is Formidable, and Surrender is Impossible.

Instruction: The sustained use of instruction skill on a body of troops can affect their troop quality as discussed on page 61 above.

Admin/Legal: For each level of skill (not asset), treat the unit as being one hex closer to its supply base for purposes of determining supply.

Mapping: Leaders with mapping skills may roll a Formidable task vs. Mapping each turn to find the best path through terrain for the turn. Outstanding Success multiplies the unit's movement allowance by 1.5 (round to the nearest whole number), success adds 1 to the movement rate for the turn, failure has no effect, and Catastrophic Failure subtracts 1 from the turn's movement rate (the unit got lost). Note that leg infantry units get no greater benefit for Outstanding Success than they do for basic success.

This works only for ground units, and not for lift (contra-grav) units.

Mass Combat Ratings

The mass combat ratings of the Woden and Dawn Isles armed forces are listed below, along with the rating for RC quick reaction squad.

Woden Empire:

3 divisions of foot (TL-1 Experienced)
Combat Value (each): 200; Movement Rate: 2/1

6 divisions of foot (TL-1 Novice)
Combat Value (each): 180; Movement Rate: 2/1

2 mounted divisions (TL-1 Veteran, with 5 cavalry squadrons each, 2 heavy and 3 medium)
Combat Value (each): 180; Movement Rate: 3/2

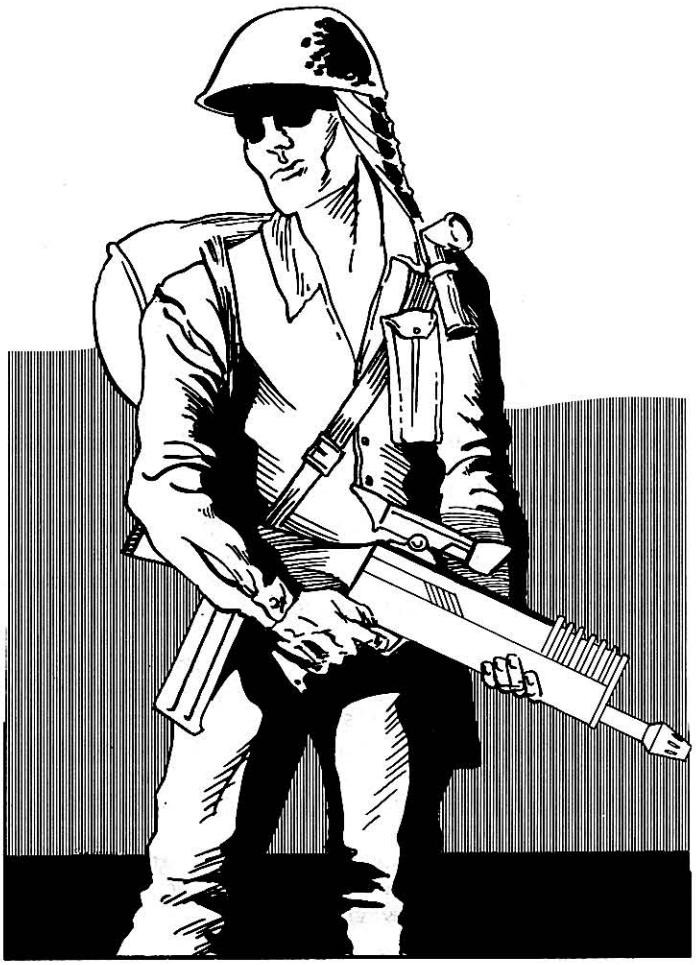
5 separate cavalry squadrons (TL-1 Veteran, light)
Combat Value (each): 18; Movement Rate: 3/2

1 Imperial Guard division (TL-1 Veteran)
Combat Value: 300; Movement Rate: 2/1

Dawn Isles:

5 divisions of foot (TL-1 Experienced)
Combat Value (each): 200; Movement Rate: 2/1
2 in Kongsholm, 2 in Aalanagrad, 1 in Sudhaven

2 cavalry brigades (TL-1 Experienced)
Combat Value (each): 60; Movement Rate: 3/2
1 each in Kongshold and Aalanagrad



1 amphibious brigade (TL-1Veteran)
Combat Value: 54; Movement Rate: 2/1
Kongsholm

2 Marine battalions deployed as ship's troops (TL-1 Veteran)
Combat Value (each): 18; Movement Rate: 2/1
Based out of Kongsholm and Aalanagrad, but mostly at sea

1 arquebusier battalion (TL-2 Elite)
Combat Value: 60; Movement Rate: 2/1
Kongsholm

Reformation Coalition:

1 Marine squad deployed as orbital quick reaction team (TL-11 Veteran)
Combat Value: 3; Movement Rate: 2/1

USING THE ECONOMIC MODEL

Some referees may wish to play out the bootstrap campaign with a full-up economic model. Because this model is designed primarily for the more manageable scale of a colony of a few hundred persons rather than a nation of a few million, this will require some additional preparation from the referee.

The map of the Dawn Isles on page 60 is already rendered with the 20-km mapping hex grid, but this will probably need to be enlarged to allow detailed inspection and use (GDW grants permission to owners of the **World Tamers Handbook** to make photocopies of this map for purposes of enlargement, etc., as required for play of the scenario). The population of the Dawn Isles is 20,000,000 persons, and referees can assume that all infrastructure for this population is already in place. The referee will have to place the population, capital goods, and determine which land is currently under use for agricultural and raw materials purposes. Population and industrial capital will be concentrated in the two main communities of Kongsholm and Aalanagrad, but there will also be smaller such pockets in Sudhaven and the other settlements indicated on the map. Agricultural and raw materials land will be scattered out around these cities and settlements, and all cities and settlements are connected by a minimal TL-1 road net.

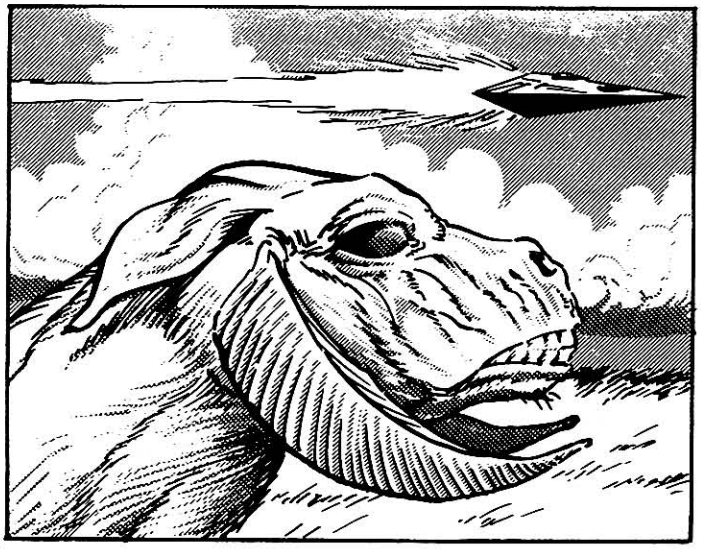
The data used with the economic model is presented on page 50, but this is not available to the PCs until they complete goal-oriented surveys of these hexes. This task will require all four of the scientists detailed to the Base Team, and the PC leaders may wish to detail more personnel to the survey tasks to cut the time required. For purposes of the time reduction factors (see page 20), the ad hoc orbital station left by *Immanuel Kant* is considered to be a spacecraft.

Note that if the four B Team scientists are being used for a survey, the number of development operations that may be conducted by the B Team per month is reduced to 3 (from 4), and may not include geologist or metallurgist tasks.

The various tasks conducted by the members of the action and base teams also have an impact on the output rolls of the economic model as indicated in "The Jobs" section beginning on page 61. These DMs are used during monthly turns in which tasks were allowed by negotiation with Holmgren and were rolled as successes.

RANDOM EVENTS

Once the bootstrap team is settled in and begins functioning, the campaign moves to a high level. Events begin to happen once a month that affect the campaign.



Weather Events

Use the weather events table found on page 36 of Chapter 4.

Scenario Specific Random Events

Use the table below for bootstrap campaign random events, in place of the Random Events table found in Chapter 4. As with the table in Chapter 4, roll 16+ on 1D20 to see if this table should be consulted. Otherwise skip this table for the month.

D20	*Result*	*Political Roll DM*
1	Disastrous Plague	See notes
2	Disastrous Livestock Disease	See notes
3	Serious Plague	See notes
4	Serious Livestock Disease	See notes
5	Holmgren Has Heir	+2
6	Holmgren raids Woden	See notes
7	Woden raids Dawn Isles	See notes
8	Holmgren invades Woden	See notes
9	Woden invades Dawn Isles	See notes
10	Personal Event	See notes

Disastrous Plague: Very serious disease strikes people of the Dawn Isles. 1D20×10 persons die each day until Impossible Medical (Diagnosis) task is completed. Referee must randomly determine settlement in which task breaks out, and task may not be rolled until a bootstrap medic arrives in the hex. Task may be rolled once per 24 hours thereafter. If plague is stopped before 500 persons die, +4 on Political roll for this turn, +3 if before 750, +2 if before 1000, +1 if before 2000. Otherwise –4.

Disastrous Livestock Disease: Very serious disease strikes livestock: Kills 1D20 units of livestock until Impossible Medical (Diagnosis or Veterinary Medicine) task is completed. Referee must randomly determine settlement in which task breaks out, and task may not be rolled until a bootstrap medic arrives in the hex. Task may be rolled once per 24 hours thereafter. Due to diseased meat, agricultural output cut in half for this turn. If disease stopped before 50 units die, +4 on Political roll for this turn, +3 if before 75, +2 if before 100, +1 if before 200. Otherwise –4.

Serious Plague: Serious disease strikes people of the Dawn Isles. 1D6×5 person die each day until Formidable Medical (Diagnosis) task is completed. Referee must randomly determine settlement in which task breaks out, and task may not be rolled until a bootstrap medic arrives in the hex. Task may be rolled once per 24 hours thereafter. –2 DM on all output rolls this turn. If disease stopped before 75 people die, +2 on Political roll for this turn, +1 if before 150. Otherwise –4.

Serious Livestock Disease: Serious disease strikes livestock: Kills 1D6 units of livestock until Formidable Medical (Diagnosis or Veterinary Medicine) task is completed (task may be rolled once per 24 hours). Due to diseased meat, agricultural output reduced by 25% for this turn. –1 on political roll. If disease stopped before 15 units die, +2 on Political roll for this turn, +1 if before 30. Otherwise –4.

Holmgren Has Heir: Holmgren's Queen Christina gives birth to a healthy son by cesarean section performed by a bootstrap doctor after a long and difficult labor. Holmgren is ecstatic with joy, and the people rejoice throughout the Dawn Isles, thanking the local diety for the heir and for the bootstrap team for saving him and the Queen. Holmgren and Christina have been married for more than a decade and nearly gave up hope of having a child.

Holmgren raids Woden: Holmgren wants to stage a raid on Woden to demonstrate the increasing effectiveness of his armed forces, and to raise the morale of his people (perhaps in response to event below). This raid will involve bootstrap team military advisors. He wishes to select a limited goal which will have a noticeable effect, but

which can be accomplished with a relatively small operation. This event proceeds at referee's discretion, as it should involve planning and participation by the bootstrap leaders (especially if they are PCs), and should be resolved using the mass combat system in Chapter 5.

A successful raid will yield +DMs on the political roll, while failure will yield –DMs.

Woden raids Dawn Isles: A small naval force from Woden will sortie to land troops and hit a Dawn Isles coastal settlement (perhaps in response to event above). Bootstrap intel team members will have an opportunity to get advance notice of the raid and prepare for it, either by agents in Woden, or via the coastwatcher network. Further details are up to the referee, but should involve PC participation, either as intel geeks, security specialists, military advisors leading Dawn Isles ground troops, or the bootstrap leaders. Event should be resolved using the mass combat system in Chapter 5.

Repulsing the raid with minimal losses, or maximum damage to Woden, will yield large +DMs on the political roll, while the reverse will yield the reverse.

Holmgren invades Woden: Holmgren wishes to stage a major invasion of the Woden mainland to attain major goals. The bootstrap team will be involved in all major aspects, from intelligence gathering to planning to accompanying the ground troops as advisors. Event proceeds at referee's discretion with low-level roleplaying, high-level planning, and resolution in accord with the mass combat system in Chapter 5.

DMs on political roll are commensurate with results, ranging from +10 (national defeat of Woden, capture of Rudolph the Bald) to –10 (loss of entire army in overseas operations).

Woden invades Dawn Isles: Major invasion by bulk of Woden army. Except for difference in scale, similar to notes for the Woden raid above.

DMs on political roll are commensurate with results, and should range up to +8. There is no lower limit, as the lower limit would be the utter defeat of the Dawn Isles and the destruction of its government, obviating the political track.

Personal Event: Roll 2D6 on the following table. Use the table as a random generator to set up low-level roleplaying situations. Low-level roleplaying can actually reverse or cancel the effects of these results.

2D6	*Event*	*Political Roll DM*
2	Rescue by native	+2
3	Rescue by team member	+2
4	Aid by native	-1
5	Aid by team member	-1
6	Friendship	0
7	Cooperation	0
8	Argument	0
9	Minor Crime by native	-1
10	Minor Crime by team member	-1
11	Major Crime by native	-2
12	Major Crime by team member	-2

Rescue by Native: A member of the bootstrap team is rescued from a dangerous situation by a local person.

Rescue by Team Member: A local person is rescued from dangerous situation by a member of the bootstrap team.

Aid by Native: A member if the bootstrap team is helped in a difficult situation by a local person. This may be an intellectual or "knowledge event" rather than an action event.

Aid by Team Member: A bootstrap team member gives a great deal of help to a local person which is greatly appreciated.

Friendship: Locals and team members strike up strong friendships including romantic relationships, possibly leading to marriage. Team members become part of the community rather than guests.

Cooperation: Locals and team members cooperate and work well with each other.

Argument: One or more arguments break out between team members and key members of the local population.

Minor Crime by Native: One or more natives commit a minor crime against a team member or team facility. Roll on the Minor Crime table for the crime.

Minor Crime by Team Member: One or more team members commit a minor crime against a local person. Roll on the Minor Crime table for the crime.

1D6	*Minor Crimes*
1	Brawl
2	Fight
3	Bribery
4	Petty Theft
5	Custom Violation
6	Insult

Reroll if the crime was committed by a native and the result was "5: Custom Violation." This result indicates a team member accidentally violated a native custom such as walking on sacred ground or knocking over a sacred statue, etc. The "Insult" result is not exactly a crime, rather it's an indication that one person's behavior was deliberately or accidentally insulting to another.

Major Crime by Native: One or more natives commit a major crime against a team member or team facility. Roll on the Major Crime table for the crime.

Major Crime by Team Member: One or more team members commit a major crime against a local person. Roll on the Major Crime table for the crime.

1D6	*Major Crimes*
1	Theft
2	Rape
3	Assault
4	Robbery
5	Kidnapping
6	Murder

Rudolph the Bald, Emperor of Woden

Experienced NPC

Combat Assets: Armed Martial Arts (Large Blade), Archery

Other Assets: Leadership 12, Persuasion 12, Ground Tactics 12, Riding 12, Willpower 10, Streetwise 10

Motivation:

Spade King: Rudolph and his bands rode out of the continental outback 20 standard years ago and conquered the coastal cities, establishing the Woden Empire. He will use every means in his power to satisfy his ambition, conquering all of So Skire. Two things stand in his way: Holmgren and the priests of the Southern Republic.

Club King: Rudolph enjoys watching others suffer and has fun inflicting pain. He doesn't care who is hurt as long as his lust for power is satisfied. He keeps his followers terrorized by his rages and by occasionally killing one of them in front of his court.

See **TNE** pages 210-212 and **Traveller Players' Forms** for more information on the use of animal encounter tables.

World: So Skire **UWP: X-657843-1** **Terrain Type: Prairie** **Other Information: Gotland**

CHAPTER 7: COLONY

Colony ('käl-ə-nē) n. 1. A group of people who settle on a distant world but remain under the political jurisdiction of their native world. 2. The region thus settled. 3. A territory distant from the state having jurisdiction or control over it. 4. A community of people of the same nationality or pursuits.

BALDUR

Life is tough on Baldur. Ask any Balduri. They spend day after day inside a dome on the seabed of a poisonous ocean. Some say that the only thing between a Balduri and boredom is the fight to survive. The only way Balduri ever see the sky and stars is aboard an outbound starship. Life is tough, disciplined, and crowded. The Balduri are tough, disciplined, and dependable. But even the toughest Balduri feel the urge to walk freely under an open sky. No wonder people say they appear to have their bolts screwed in a little tight.

THE VENTURE

Your group is on Baldur after a long series of freelance recovery and scouting operations into the Shenk and So Skire subsectors. Your ship is in Baldur's orbital yard for a long overdue annual maintenance and refit. You thought you would have made more than enough cash from the recovered jump drive you sold at Auction to pay for the maintenance, but with a splendid display of irony, the yard master's office just gave you the news that you need a new jump drive of your own. 80 years of shoving a scout through jump space has just worn out the old one. Clansman *isn't going anywhere for a long time. So, you order her put into orbital storage, arrange to have your personal belongings shuttled down, and you start looking for "honest work."*

Referee's Note: If the PCs played the "Survey" campaign in Chapter 3 of this book, the referee may have had them produce the survey results for Poyzen (So Skire 1736) themselves and sell it to the Balduri government. Naturally the means by which the players arrive at the outset of this venture must be adjusted for each PC group.

One evening at dinner, the group overhears two Balduri government officials talking about the new Colonial Office. If the group is interested in what they are hearing, they may make an attempt to join in. Since they are dining in a convivial atmosphere with plenty of wine and good food, the two Balduri are curious about the off-worlders and welcome their company (Carousing or Liaison: Easy). The characters meet Dimitri Rostov and Stefan Burg, a Balduri and Oriflammen, respectively, both newly appointed as senior managers in the Colonial Office. After some initial small talk during dinner, the table is cleared, brandy is ordered all around, and the conversation proceeds to weightier matters.

"Baldur is a member of the Reformation Coalition, but cannot allow others to be the guarantors of its future. Although the Coalition stands for many of the things we Balduri support, we need the means to stand on our own if need be, because we have unique needs which the Coalition may not be able to meet. At the same time, any growth in our strength means that we will be able to provide that much more energy and leadership to assist the Coalition as a whole," Rostov explains.

"Our government has formed the Colonial Office, a government department tasked with finding worlds suitable to the establishment of colonies. These colonies will allow Baldur to meet more of its own needs in terms of raw materials, as well as providing materials to trade for the things that we need. In addition, the establishment of these colonies will advance the goals of the Coalition to expand the benefits of trade and civilization as rapidly as possible. And rather than suffering through interminable Assembly debates about how such colonies should be established under joint RC leadership, by proceeding on our own we can start the job more quickly, and therefore earn the benefits more quickly as well.

"This venture is co-sponsored by Oriflamme, which like Baldur has been frustrated by the lack of priority that the RC has given to the development of the trailing frontier," says Burg. "Both worlds feel that if this half of the Coalition is to prosper, it needs to take matters into its own hands. Not only will these colonies provide bases for further expansion and defensive buffers against threats from the Wilds, but they should prove to be profitable trading partners and sources of valuable raw materials. This might include rare earths and radioactives, or pharmaceuticals from plants and fungi, or especially for Balduris, naturally-produced luxury foods such as fresh meat."

"As you know from the prices in this restaurant," chimes in Rostov, "a steak is a rare and expensive treat on Baldur after a lifetime of eating processed yeast proteins. Whoever set up a food raising and export venture or dug a lanthanum mine on a colony world could get rich very quickly with the right exports."

"However," Rostov continues, "Baldur does not have a large body of experienced explorers, scouts, and leaders, 'world tamers,' I believe they are called."

"And Oriflamme's resources have been prioritized for other areas," Burg adds.

"The Colonial Office is looking for people to participate in or lead these colonial expeditions, people with plenty of off-planet experience and a multitude of talents," says Burg as Rostov nods approvingly. "Perhaps your group would be qualified, and interested."

If the PCs are interested, Rostov and Burg can collect information and credentials from them which will allow the Colonial Office to assess the group's qualifications.

The Offer

Several days later, the players go to the Colonial Office to discuss the mission. Once again, they meet with Rostov and Berg, who explain that they are satisfied that the group meets the Office's qualifications.

"This is a one year assignment," they explain. "It's not without its risks. After recruiting and training, you'll be loaded aboard *Cumulus*, a relic freighter we recently recovered in Alpha Crucis. She's capable of jump 4 if her drives hold together."

"This job does have its rewards. If you stick it out for one year and have begun shipping out exports by the end of that time, you will find Cr100,000 in each of your bank accounts on Baldur, and *Clansman* will have a new jump drive. Of course, we will have used *Clansman* for some of our own work while you're away.

"We'd like to offer you each a berth in the expedition. If you accept, here is where you will be going." says Berg, projecting the data for Poyzen on the wall behind him.

Referee: Hand out copies of the pages 77-79 (located at the end of the chapter) for the players to examine. These pages represent the data which the characters are being shown in the briefing. After the players have reviewed the data, the briefing is concluded.

"Want to sign up?" asks Rostov, handing the characters a contract and a pen.

PLAYERS: DO NOT READ BEYOND THIS POINT.

REFEREES' NOTES ON POYZEN

1. The Balduri planners have already selected the intended colony site, the island marked on the global data view, and shown in more detail on the close-up map. Unless the players prefer to pick their own colony location, they will be given data on the intended colony location on the island. The economic model data for this planetary hex is as follows.

Agricultural Richness: 1.5
Agricultural Useable Area: 80%
Raw Materials Richness: 120
Raw Materials Useable Area: 25%
Fossil Fuels: Yes
Radioactives: Yes
Extractable Hydro Power: 1050 kW per 20-km mapping hex
Extractable Wind Power: 157.5 MW per 20-km mapping hex
Base Latitude Temperature: +28°C
Summer Maximum Temperature: +40°C
Winter Minimum Temperature: +11°C
Weather Factors: 0

2. Contrary to the survey data, Poyzen is inhabited. The Scout base staff was cut off from Cobham and the base was destroyed by a Vampire raid. The survivors fled into the nearby mountains and reverted to a base sustainable tech level of 0. Living in caves, they have managed to develop communities totaling some 5000 people. The largest community of about 2000 people is run by the Chief Scout, a TED armed with the base's few remaining working laser rifles and a solar cell recharger. His authority is on the wane as other inhabitants move off into distant communities, mostly in the mountains and jungle of the continent's west coast (the continent is indicated on the map with the symbol for the old scout base, and is just to the west of the planned colony location). Everyone else is armed with spears and clubs.

PROCEEDING WITH THE CAMPAIGN

At this point, the adventure can proceed in one of two ways, depending on your players' capabilities and interests, and whether you will be running a primarily high level or low level campaign. Throughout this campaign at appropriate locations you'll see suggestions for using your players in a high or low level campaign. In the first example below, high level players can become involved in the complexities of recruiting NPCs. Low level players simply sign on with the expedition under the leadership of NPCs.

High Level: If your group is to be the leaders of the colony expedition, they make a deal with Rostov and Berg to lead the operation. The next step will be finding and recruiting some 100 colonists and traveling to Poyzen.

Low Level: If your group is looking for jobs on the expedition, Rostov and Berg are doing the recruiting. They will also be leading the operation. For players with a military background, there is plenty of opportunity for work as members of the expedition's security team and police force.

GETTING THERE

The colonial expedition has been given the use of the relic freighter *Cumulus*. *Cumulus* will load the characters and the voluntary colonists and depart for Oriflamme. Here, *Cumulus* will load additional colonists and livestock and equipment for the expedition. *Cumulus*' specifications can be found on page 107. Two other starships useful for colony transport can also be found in the equipment section. These can be used in other colony adventures, or enterprising PCs can perhaps convince the colony sponsors to allocate additional shipping to establish the colony.

Colonial transports like *Cumulus* are not luxury liners. They are designed to provide relatively cheap transportation to a large number of people, their personal possessions, livestock, equipment, and provisions for the colony. Colonists are carried in a portion of the cargo hold fitted with half-bunks. The half bunk is a light frame bunk stacked two-high with just enough adjacent locker space for the individual's personal possessions. Each half bunk displaces seven cubic meters, weighs 250 kilograms, and costs Cr25.

Once *Cumulus* is finished loading at Oriflamme, she will jump to Tuer, refuel, and make the short Jump-1 hop to Poyzen.

COLONISTS

Colonists are a diverse group of people who settle a new world for a number of reasons. Some go to start a new life with new opportunities. Others are running from their past, or to escape from a poor environment. Still others relocate because they have no choice. These people range from highly motivated, highly skilled professionals through yeoman farmers to shiftless ne'er do wells and forced deportees who may be criminals or chronic malcontents. The PCs will have to deal with them all.

The sections below deal with the colonists on a fairly detailed level, in order to allow low-level roleplaying in the colony campaign. However, these colonists will also be described in terms of the Chapter 4 economic model.

Voluntary Colonists

The characters must spend at least two weeks advertising for voluntary colonists. The number of colonists available depends on on the planet's population (the method used below to calculate these numbers can be used for any planet; Baldur's statistics are noted below for use with this particular campaign) and the type of colonist willing to emigrate to a new world. Each voluntary colonist will pay steerage passage plus Cr1000 to join the expedition. The number of colonists that can join the expedition depends on the passenger capacity of the transport. This is the hold capacity remaining after space has been allocated for rations, capital, weapons, and whatever equipment is being carried.

Recruiting Voluntary Colonists: There are four categories of voluntary colonists to be recruited. These include *professionals*, *artisans*, *farmers*, and *others*.

The detailed recruiting described below is included for a campaign that will have the capacity for high and low-level play. The high-level play is demonstrated by the fact that the PC leaders are having to make the choices of who to bring along. The low-level *potential* is demonstrated by generating colony members in sufficient detail to allow meaning roleplaying opportunities later on, and can actually be turned into immediate low-level play by conducting interviews with the prospective colonists.

However, if the PC colony leaders are not particularly interested in the potential for low-level play, and simply want to run a colony solely via the high-level economic model presented in Chapter 4, there is no need to go through with any any detailed interviews or creation of templates. However, unless the PC group is confident that they possess all skills that may be needed to respond to random events (Medical and Veterinary skills, etc.) they should still recruit a handful of professionals with known skill levels to meet these needs.

Professionals: These are volunteer colonists with useful professional skills. They would be commissioned characters (where appropriate) drawn from careers such as Law Enforcement, Medicine, Veterinary Medicine, and Science. Individuals with Engineer skills, and retired Army or Marine officers would also be included in this category. Professionals are primarily used as important NPCs with crucial skills, and are therefore intended for low-level roleplaying, and cannot really be easily classified in terms of the economic model.

The number of professional individuals interested in joining the colony equals the home world's population number (Baldur's is 7) plus the highest Recruiting skill level in the PC group. The referee should roll up professionals as detailed NPCs for the players to consider as colonists. In addition to considering their career qualifications, the players may wish to interview these professionals. See Chapter 6, Bootstrap, for the interviewing procedure.

In addition to the recruiting procedure, the referee should secretly consider the attitude of each of the professionals reaction to the PCs. Do they support what the PCs are doing? Will they attempt to subvert the PCs and attempt to take over the colony? Will they simply not get along and sow discord? The referee can simply establish these conditions based on his or her plans for the unfolding campaign, or can determine these things randomly by drawing motivation cards or rolling 2D6. The table below gives an example of how this could be done, but referees should feel free to expand the detail of this table. Naturally the PCs can determine these details only by a successful interview process which includes successful rolls on Interview, Interrogation, or Psychology.

2D6	*NPC Professional's Attitude toward PC Leaders*
11-12	Identifies with and strongly supports PCs' goals, and the PCs' interpretations of them
9-10	Supports the PCs' goals and will not actively oppose the PCs, but may sometimes in good faith publicly disagree with the PCs on how best to accomplish these goals
6-8	Willing to be led by the PCs, but will respond accordingly to good or poor treatment

4-5 Agrees with the PCs' goals, but will attempt to subvert the PCs' leadership in order to take over leadership of the colony

2-3 Is opposed to the PCs as well as their goals

Artisans: Each year living in the domes became more oppressive, as she tried to keep running the business that she had founded with her husband—machining and repairing replacement parts for the relic high-tech machinery. Ever since her husband had been killed in a bulkhead collapse three years ago, that life had become increasingly grim. She missed his stories about the worlds beyond the murky sea and murky sky, and his gentle advice on recreating the precise countours of power shafts and transfer gears. She needed a fresh start, someplace where she could be reminded of something besides what she had lost. Last night, she saw it on the news video. A colonial expedition was heading out into the Wilds to settle the empty garden planet discovered six months ago. She could have her own shop, fixing and taking care of all of the colony's tools, and building new implements from the native metals she smelted herself. She could see for herself the worlds he had told her about and practice her trade in a new way. With her skills as a metallurgist, she knew she could do it.

These are volunteer colonists with useful technical skills. These may come from any career but must have a skill from the Technician, Artisan, or Engineer skill clusters. In the economic model, artisans would primarily be industrial and materials laborers, although there are some exceptions to this. For example, a Hunter would be considered a special type of Artisan, and would be included under agricultural laborers or armed forces laborers, depending upon how the colonial leaders intended to use his or her skills.

The number of artisans interested in joining the colony equals two times the quantity of the home world's population number plus the highest Recruiting skill level in the PC group (for Baldur this is 2×[7+Recruiting]). The referee should determine the statistics and skills of these individuals using the NPC templates assigning them skills from the Technician or Artisan skill cascades. If desired, the players can select higher skilled individuals and generate complete UPP statistics and skills as well as interview them using the bootstrap interview procedure.

Farmers: We hadn't had a good harvest in three years, and the crops we did grow we had to sell to the technarchs at their prices. Sure, the barony provided materials to keep putting crops into the ground, but you pay them back one way or another, and I was close to losing my freedom and becoming tied to the land. It's hard to throw away a lifetime of work, but at least if I leave now I can leave—call it breaking even by walking away with my freedom, and that of my wife and kids. I hear there's a chance for a fresh start, though. A starman came to the grange hall last week, telling us of a new world they want to settle with farmers just like us. A world so rich you can get four crops a year. Crops that we sell for money that goes in our pockets. And land that's almost endless, a place to expand where my kids can have their own land some day. Is there any question about the right thing to do? Let's go! To the stars!

Farmers are colonists with experience farming the land and handling domestic animals. They will have at least Farming skill and be the backbone of any colony. (*Note*: farmers are not available on Baldur; these will have to be recruited from Oriflamme. The nearest thing the Balduri have to farming is tending yeast vats.) Farmers are obviously considered to be agricultural laborers for the economic model.

To determine the number of farmers interested in joining the colony, roll a number of D6 equal to four times the quantity of the world's population number plus the highest Recruiting skill level in the PC group (for Oriflamme, 4×[8+Recruiting]). Each will have at least Farming 1. The players may wish to interview one out of ten farmers to determine their UPP statistics and skills using the NPC templates. Additional skills come from the Animal Handling skill cluster, including Veterinary Medicine, but may optionally include Gun Combat or Mechanic. If desired, the players can interview higher skilled individuals and generate complete UPP statistics and skills for them.

Families: *There's a lot of talk about the dawn of a new era and how the universe is starting over again, like a little baby. Well it doesn't look much different from where I'm sitting. The bulkheads still creak at night, and people are still scrounging to keep the old machines working for just one more month.*

I suppose I'm used to it, but I didn't take a wife just to doom her to more of the same until she's old and tired of waiting for a brighter future. She deserves better, and our kids deserve better, and I'm going to see that they get a look at this bright new dawn that people are building.

They're recruiting people for this new colony and we're going to be part of it. I don't know how to farm, but I can learn. That's what fathers and husbands are for, is to do what needs to be done, and I'm going to be a good one. I don't have all the money for our fare, but I'll get the rest of it somehow. Me and my family are going to build a new world—a world for us, a world for everyone.

Most colonists will have families, and this is allowed for in the economic model by treating each laborer as 1/4 of an actual full-time worker. Therefore it is simple to calculate that, on average, the colony consists of four-person families each with one full-time worker.

For low-level roleplaying purposes, however, important families who will interact with the PCs on a detailed and regular basis should be generated in detail. Roll 1D6 for the number of adults in the family: 1 = 1, 2-5 = 2, 6 = 3. Roll 1D6–2 for the number of children. Ages, sexes, and other details of children and adults is at the referee's discretion.

Others: Colonists with any background. They are mostly city dwellers with no particular useful skill. Unskilled colonists with military backgrounds would be useful as security specialists and members of the colonial militia. (If your characters are playing a low level campaign, this is probably where they will fit in.) For the economic model, these are laborers who can be assigned to any sector, as they will be able to learn what they need to do their jobs.

Roll a number of D6 equal to eight times the world's population number plus the highest Recruiting skill level in the PC group to determine the number of other voluntary colonists interested in joining the expedition (for Baldur this is 8×[7+Recuiting]). The players may wish to interview one out of ten individuals in the other category to determine their UPP statistics and skills using the NPC template system. Their skills may come from any career or skill cluster.

Involuntary Colonists

When *Cumulus* reaches Oriflamme, she'll be taking on more than farmers, livestock and equipment. Conveniently not mentioned by Burg (assuming that he even knew) when the characters were recruited were the Oriflammen colonists that were coming aboard—not of their own free will.

For a number of years there has been a small but growing resistance movement against the feudal technocracy governing Oriflamme. The recent growth in this movement was sparked by Marines returning from the Wilds where their experiences have turned their political sentiments against any sort of feudalism. Whole cities on the planet have become hotbeds of anti-government feeling. Some direct action, such as bank robberies in the name of the resistance, provocative graffiti painted on public walls, and an occasional letter bomb have taken place. However, open revolt has not yet broken out. Nonetheless, there have been wholesale roundups of suspected ringleaders and sympathizers. And what better way to eliminate troublemakers but to send them to the stars?

After the farmers are loaded at Oriflamme, any remaining free passenger space in the cargo holds—but not exceeding 50 percent of the total colony population—will be filled with involuntary colonists

and their families by the Oriflamme security apparatus. 90% of these involuntary colonists are undesirables and their families (no point in making people angry and leaving them on Oriflamme), 10% are criminals. As the Oriflamme government is attempting to quietly "dump" these people, it provides no documentation about their actual circumstances to the colony leaders.

Note that from the point of view of the economic model, the PCs will not be able to distinguish these colonists from the "Other" colonists generated above. The "Other" colonists will simply be added together with the Involuntaries for a total number of laborers which the PCs will have to assign to economic sectors without being able to distinguish between the reliable and unreliable workers. PC colonly leaders will only be able to tell the voluntary "Others" from the involuntaries by making a specific effort to do so, such as interviewing (conducting regular Observation, Psychology, Interview/Interrogation, and Admin/Legal tasks) or via low-level roleplaying, at the referee's discretion. Even in this case, the PCs may not be able to tell the criminals from the undesirables.

Undesirables: *I was walking home after looking for work and minding my own business when the cops sprung a snap trap on the street. Lines of them sealed off the block and moved in, questioning anyone standing there. If you gave them any lip or made a sudden move, you'd get a crack on the head and thrown in the wagon. The sergeant said I looked healthy, and two of his men grabbed me and threw me into the prisoner van. After a long ride in the dark, we were emptied into a holding pen full of people. Some were crying, others were sick, waking up from the blows. We could look through the wire and see the blast berms and concrete landing pads of the downport. There was a large shuttle on one of the pads. The guards had strung a barbed wire corridor between our pen and the shuttle. "There's your new home," one of the guards said. "You're off to a new world."*

"But what about my wife?" I said.

"Oh, sorry," he answered. "We'll round her up and send her along next time."

Treat these as Others listed above. They may be from any career. These persons will not necessarily be opposed to the player characters' goals, but the circumstances of their inclusion in the colony may well make them uncooperative. These may be assigned to any economic sector.

Criminal: *Me 'n' the guys just finished knocking over this mom 'n' pop store when the reds and blues came on and we wound up inside the pigs' van faster'n we could blink. The judge gave us a choice: jail or some jerkwater colony where they don't even have running water. I'd been in jail before, too many times. Maybe the colony would work out, full of hicks that are easy pickin's. Maybe a couple of the guys would like to come along and we could set up a real nice operation. After all, the judge called the colony a land of opportunity.*

These may be from the Criminal, Tough, or Bureaucrat careers. At some point during colonization, these individuals will resume their criminal careers on the colonial world and actively work against the player characters. These may be assigned to any economic sector.

THE COLONY

Two weeks and two jumps out of Oriflamme, *Cumulus* enters the Poyzen system. After a quick fuel stop at the outer gas giant, she heads in-system and enters orbit around Poyzen. The colonists fidget aboard *Cumulus* while her captain and the colonists' command group meet and confer about the landing site. Although the leaders will have chosen a site before this, there is always a chance for a last-minute change, should anything appear amiss. The first survey crew recommended that the colony be established on a large island near the equator. There was fresh water evident both from orbit and confirmed by the ground survey. The colony site is on a sheltered bay which could eventually become a seaport. The terrain was open and rolling, with pockets of forest, assuring a supply of wood and farmland. Most importantly, there is no sign of any indigenous habitation.

PC leaders or security teams may wish (or be ordered) to conduct a final reconnaissance of the ground before commencing the irrevocable debarkation. If they haven't thought to do this before, they should make sure that they have arrived at the correct time of year: at the beginning of the local growing season. It would be a shame to arrive as the first snow is falling with only a month of rations...

Debarkation

As soon as the landing zone is secured, the ship's crew will begin shuttling down the colonists along with their rations, capital goods, and tents for temporary shelters.

Start-Up: See page 36 for start-up assumptions.

Mapping: It is at this point that the PC colony leaders should prepare their sketch map of the colony's placement, showing the location of agricultural land, housing and industrial capital, materials capital, roads, food storage areas, power generating facilities, and the like (these should all be within the same 20-km hex). This detail is not necessary for the economic model so long as they are all in the same hex, but will be essential for low-level roleplaying.

Reviving Livestock: This is the responsibility of the colony's veterinarians (usually recruited as professionals). Each low berth worth of livestock (10 rations worth of livestock are carried per livestock low berth) is rolled as a discrete task: Average: Veterinary Medicine. Failure indicates that the revival failed and the livestock is dead. Be sure to keep records on how much livestock is successfully revived, as this will affect the output of the agricultural sector.

Starport

The colony's starport will be a bare area of ground, or a lake or ocean bay if the land is too rugged for a safe landing. Other than a navigation beacon, it will have no facilities until the colony develops beyond its first primitive state, and will be treated as Class X. By purchasing (either by local manufacture or by import) a fuel purification plant, the colony can upgrade this to Class E. Until then, incoming starships will have to refuel at local gas giants or use oceanic refueling.

THE FIRST YEAR

The first year of any colony's existence is critical to its survival. This year teaches the colonists how to survive the rigors of a new world including severe seasonal weather, contact with indigenous people, native wildlife, and the compatibility of local soil and plant life with the colonists' crops and livestock. This is also a testing time of the PCs' leadership abilities. How the players govern and cope with various problems as they arise may mean the difference between a stable, cohesive colony and one that is broken into fighting factions.

The first year is played out on two levels. PCs and NPCs go about their jobs on the low level of day-to-day interactions that can be played out face to face. On the high level, the colony's leaders deal with the more abstract aspects of the colonial economic model, dealing with major events month to month, and tracking such vital statistics as livestock survival, food production, and gains and losses in the colony's population through deaths and births.

Jobs

Colonists have a wide variety of jobs that suggest adventure scenarios which can be played out in low-level roleplaying. These include:

Farmers (Agricultural Laborers): These are the backbone of the colony. They may or may not have farming skill or experience. Farmers plow the fields, plant, cultivate, and harvest the crops, and care for the livestock. Farming is usually mundane work, but now and then man or nature intervenes and the farmer must cope with an emergency. Farms by their nature tend to be isolated, and farmers often have to face a hostile environment on their own.

TEMPLATE NPCS

Here are a number of template NPCs used for low-level roleplaying as the PC leaders establish and run the colony. As noted above, professional voluntary colonists are generated as detailed NPCs. The remaining voluntary colonists—artisans, farmers, and others, as well as involuntary colonists and a few additional types, are presented here as template NPCs.

Artisan

Artisans provide the colony with useful technical skills. They may be blacksmiths, carpenters, masons, or if the colony's tech level is high enough, machinists or mechanics. These are the people who build the buildings, machinery, and artifacts that enable a colony to function.

Economic Model: Industrial or Materials Laborer

Level: Novice

Combat Assets: Armed Martial Arts (Club), using trade tools, hammers, axes, etc.

Other Assets: Bargain 8, any two of Carpenter, Jeweler, Mason, or Metallurgy, one at 12, the other at 6. If the local tech level supports these skills, add Electronics, Machinists, and Mechanic to the possible skill list.

Hunter

Hunters may be recruited to help the colonists locate and kill local game during the colony's initial stages. They may also serve as scouts and trackers, particularly if indigenous inhabitants are discovered on the colony world.

Economic Model: Agricultural or Armed Forces Laborer

Level: Veteran

Combat Assets: Choose two from Slug Weapon (Slug Rifle), Archaic Weapons (Archery), Armed Martial Arts (Small Blade), Unarmed Martial Arts.

Other Assets: Any four from **Perception, Acrobat, Explore, Animal Handling** (Riding, Guard/Hunting Beasts), Small Watercraft; one at 14, three at 10

Farmer

The farmer is the backbone of the colony. He or she grows the food the colony must have to survive and prosper. The more efficient the farming, the more labor can be freed up to produce export goods, be it luxury foodstuffs, raw materials, or even manufactured goods. The farmer is a highly skilled individual with the knowledge to grow the maximum amount of crops the land will provide and to care for a wide variety of livestock.

Economic Model: Agricultural Laborer

Level: Novice

Combat Assets: Slug Weapon (Slug Rifle), Armed Martial Arts (Club).

Other Assets: Farming 14, Riding 10, Guard/Hunting Beasts 8, Biology 9, any three from **Perception, Technidan, Explore, Determination;** one at 12, two at 9.

Veterinarian

Veterinary Medicine is the skill used in caring for diseased and injured animals and in assisting domesticated animals in various important activities such as becoming impregnated and giving birth to their offspring Veterinary doctors and technicians also inspect freshly killed meat for any diseases that may be harmful to consumers. They are also necessary to guarantee the successful revival of animals transported in low berths.

Economic Model: None; professional detailed NPC

Level: Novice

Combat Assets: *Slug Weapon*

Other Assets: Medical (Veterinary Medicine) 14, Biology 12, any two from **Animal Handling** at 10, any other two Physical Science at 8, Research 4.

Miner/Prospector

If you find resources, you need the people to exploit them. That's the job of the professional miner who digs the hydrocarbons and ores the colony needs to build its infrastructure.

Economic Model: Materials Laborer

Level: Experienced

Combat Assets: Armed Martial Arts (Club) using mining tools such as shovels, pry bars, and picks; Unarmed Melee Combat.

Other Assets: Construction, Excavation, Combat Engineer, all at 12; any one of the following: Technician, Geology, Carpenter, Metallurgy at 10.

Mercenary/Security Specialist

Any colony being established on a potentially hostile world will want one or more mercenaries or ex-military types along to train a colonial militia and form the backbone of any security force.

Economic Model: Armed Forces Laborer

Level: Veteran

Combat Assets: *Energy Weapon* or *Slug Weapon*, Unarmed Martial Arts, *Armed Martial Arts*, Autogun, Grenade Launcher

Other Assets: Leadership, Instruction, Recruiting, Ground Tactics, Muscle Transport, all at 12.

Other

The "Other" class of voluntary colonists are willing workers and support the colonization effort. However, they lack farming and survival skills, and may have never lived outside a city before. However, city dwellers possess a native intelligence which suits them to rapidly picking up whatever skills they might need.

Economic Model: May be assigned to any economic sector

Level: Novice

Combat Assets: Unarmed Melee Combat

Other Assets: Any two from the following: Service, Streetwise, **Technidan,** Admin/Legal, Bargain, Willpower; one at 10, one at 8.

Undesirable

These are also individuals without farming, survival, or artisan skills. However, they've been press-ganged into the colony against their will for a variety of political or economic reasons. Although not criminals in the strict sense, they may have anti-social tendencies and come from the lower strata of society.

Economic Model: May be assigned to any economic sector, are usually indistinguishable from "Other," above

Level: Novice

Combat Assets: Unarmed Melee Combat

Other Assets: Any two of the following: Streetwise, Leadership, Carousing, Persuasion, Bribery, Gambling, Bargaining, Act/Bluff, one at 10, one at 8.

Criminal

Sometimes governments will sweep petty criminals out of their jails and dump them on colonial expeditions. Or, they may be rounded up on the street and given the choice of a jail term or exile. Either way, they spell trouble for any colony.

Economic Model: May be assigned to any economic sector, are usually indistinguishable from Undesirable, above

Level: Experienced

Combat Assets: Slug Pistol, Armed Martial Arts (Small Blade), Unarmed Martial Arts.

Other Assets: Any three from the following: Leadership, **Vice, Crime, Charm, Vehicle,** Admin/Legal; one at 12, two at 10.

Resistance Fighter

Ex-Oriflamme Marine charged with treason. However, because of an excellent combat record and service to the Reformation Coalition, this person is allowed to live in exile. (Roll 1D6: on 5-6 this NPC was an officer.)

Economic Model: May be assigned to any economic sector, are usually indistinguishable from "Other," above

Level: Veteran (Officer: Elite)

Combat Assets: Slug Weapon (Slug Rifle), Slug Weapon (Slug Pistol), Armed Martial Arts (Large Blade), Unarmed Martial Arts, Autogun, Grenade Launcher

Other Assets: Survival 10 (Officer: add Leadership 13, Ground Tactics 12).

Livestock

The accompanying table is presented to assist the referee in fleshing out the abstract livestock requirements from the economic model. Assume that one ration equivalent of living livestock equals about 100 kg of animal. These equivalencies are intended to be helpful for roleplaying *color*; as the economic model contains many abstractions about food as labor vs. food as mass, food as slaughtered animals vs. food as produced by animals, players and referees should not attempt to read too much into these figures.

Animal	*Weight (kgs)*	*Volume (m^3)*	*Cost (Credits)*	*Terran Equivalent*
Draft Animal	1000	10	2000	Percheron Draft Horse
Riding Animal	600	6	3000	Quarter Horse
Dairy Animal	600	6	500	Holstein Cow
Large Meat Animal	1000	10	400	Hereford Steer
Medium Meat Animal	50	0.5	100	Meat Swine
Small Meat Animal	10	0.1	10	Rabbit
Guard/Herding Animal	50	0.5	100	German Shepherd Dog
Small Pest Control Animal	7	0.1	free	House Cat
Egg Producing Animal	4	0.1	1	Chicken

Artisans (Industrial and Materials Laborers): On a colonial expedition, these are the "village smithies." Artisans are the metal smiths that produce plow blades, scythes, horse shoes, pots and pans, and most importantly nails: all the metal tools and implements needed by the colony. Early on, this is produced from bar iron imported aboard the colony transport. Native metal sources must soon be found, however, or vital metal artifacts cannot continue to be produced.

Artisans also include the carpenters, stone masons, and brick layers who build the buildings, fences, and other structures needed by the colony to build a permanent home. Others weave cloth from local fibers and produce plates and cups from local clays.

Miner/Prospector (Materials Laborer): These find the vital fuels and metals that enable the colony to survive and grow. Although they may have to bust sod with the rest of the colony for the first few months in order to eat, prospectors also head into the wilderness looking for coal, oil, phosphates, nitrates, and ores of all kinds. Prospectors should have Geology skills to enhance their ability to find an ore body or hydrocarbon deposit, but anyone might get lucky and strike it rich.

Mercenary/Security Specialists (Armed Forces Laborers): These have two jobs: internal security and external security. Security specialists have the full time job of keeping law and order in the colony. They also supply security against any external threat. In addition, security specialists should have enough military and training experience to serve as the cadre for the colonial militia, which might be needed if any indigenous people become hostile or if a hostile party lands from off-planet.

Explorers (PCs or Detailed NPCs): As the colony grows, it will need new land for its people. Explorers have the job of finding and mapping new colony sites and transportation routes for anticipated expansion. They also are the people who answer the question, "What's out there?" Although the colony has a gross picture of Poyzen's many continents from orbital surveys, only the explorers travelling overland or by sea can fill in the fine-grained details.

Hunters (Agricultural Laborer): During the early days of the colony, local wildlife may be a valuable resource for protein. It may also be valuable for its hides and furs. Hunters are colonists who head into the outback to harvest wildlife, taking care to preserve enough life so it will renew itself.

Leadership: If the players are playing the roles of the colony leaders in a high level campaign, they will have one basic job, that of supervising, inspiring and encouraging the colony members to do their best for the good of the colony. The leaders must also respond to and cope with events that affect the colony as a whole.

Veterinary Medicine

Veterinary Medicine is a cascade skill of Medicine that may be chosen as a specialty in the Medicine career. In an emergency, Veterinary Medicine may be substituted for Medical skill using the normal cascade guidelines. The reverse is also true. Individuals who specialize in Veterinary Medicine may be commissioned as a Doctor of Veterinary Medicine, otherwise they work as a veterinary technician. There are no ranks nor promotions.

Individuals who choose a skill from Animal Handling or Physical Science clusters may receive skill in Veterinary Medicine in place of one of the skills listed in these clusters in the basic TNE rules. You may use the Veterinarian Template NPC or generate your own as the colony's "vet."

Scenario Specific Events

The events and tables which follow are supplemental to the random event tables found in Chapter 4, and reflect the specific details of this colony campaign.

Explanation of Scenario-Specific Results: Certain of the new entries on the table on the facing page require elaboration as follows.

Friendly Starship: A friendly starship arrives and assists or trades with the colony. Roll 1D6 on the table below to determine the ship type and its action.

1	Colonial Transport
2	Far Trader
3	Scout
4	Warship
5	Far Trader
6	Scout

Colonial Transport: *Cumulus* arrives with another load of colonists sent to join the existing colony. These are Agricultural and Materials Laborers with a handful of Professionals, well equipped to survive and thrive on a new world. Capital goods and livestock sufficient to employ all embarked, as well as two months of rations for those embarked. Political roll DM +1

Far Trader: A Far Trader arrives with a load of high tech tools, weapons and other trade goods useful to the colony (referee's discretion). The captain wants to sell these in exchange for fresh fruit, vegetables, grain, and meat (i.e., rations). These goods will be traded to the colony for direct cash value, without having to devalue the colony's money by dealing with exchange rates. Political roll DM +1.

Scout: A Scout arrives with news and mail from Baldur and offers to carry news and mail back home. Political roll DM +1.

Warship: An RC warship arrives in the star system. Ship's officers land at the colony and tell the colonial administrators that their ship will be on patrol in the system for a month, and will pay direct cash value (not devalued by exchange rates) for rations equal to five times the crew size. Members of the crew will also land to enjoy shore leave at regular intervals and uphold the naval tradition of freely spending credits: Agricultural sector output roll +1 this turn, Industrial output roll +3. However, on a 1D10 roll of 7+ there will be a brawl requiring 1D6×500 credits of construction industry production to repair.

If a hostile ship arrives while the warship is on patrol, the warship will attempt to protect the colony. The warship is a Victrix-class sloop (crew 26) on 1-3, a mercenary cruiser (crew 72) on 4, and a clipper (crew 150) on 5-6. Political roll DM +2 (+1 if brawl).

1	Colonial Transport
2	Corsair
3	Slaver
4	Warship
5	Vampire Cruiser
6	Slaver

Hostile Starship: A hostile starship arrives and threatens the colony. Roll 1D6 on the table at left to determine the ship type and its action.

Colonial Transport: *Cumulus* appears with 1D10×10 involuntary colonists and criminals, and no additional capital goods, live-

Random Events: This table is a slightly modified replacement for the generic random events table in Chapter 4. Some of these events are more elaborate versions of events on the original charts, in order to provide more suggestions and opportunities for low-level roleplaying.

D20	*Result*
1	Natives Encountered
2	Unfavorable Government Development, see below
3	Plague strikes populace: 1D6 person die each day until Formidable Medical (Diagnosis) task is completed (task may be rolled once per 24 hours). –2 DM on all output rolls this turn. –1 on political roll.
4	Disease strikes livestock: Kills 1D6 units of livestock until Formidable Medical (Diagnosis or Veterinary Medicine) task is completed (task may be rolled once per 24 hours). Due to diseased meat, agricultural output reduced by 25% for this turn. –1 on political roll.
5	Hostile Starship, see below
6	Vermin eat 1D10×5% of stored rations. –2 on political roll.
7	Blight destroys crops. Agricultural output for turn cut in half. –2 on political roll.
8	Earthquake: 1D6×10% of housing destroyed. –1 on political roll.
9	Vermin eat 1D6×5% of stored rations. –1 on political roll.
10	Major crime, see below
11	Minor crime, see below
12	Native animal attack, see below
13	Indigenous animals stampede, destroy 1D20 units of agricultural capital. –1 on Political roll.
14	Major crime, see below
15	No traders arrive this month, no exports sold this turn, all rations set aside for export spoil.
16	Friendly Starship, see below
17	Discovery of hardy, edible, local life form. Permanently add +2 to all future agricultural output rolls. +2 on political roll this turn only.
18	Population explosion of local edible lifeforms. Multiply agricultural output by 2 for this month. +2 on political roll.
19	Favorable Government Development, see below
20	Natives Encountered

stock, or rations. These are dumped into the new colony's economy and social structure with criminal tendencies and no useful skills. –1 on Political roll.

Corsair: A Corsair attacks the colony with a small landing force attempting to seize whatever valuables are on hand. Low-level roleplaying negotiation results may allow them to be placated by donations of colony exports. If the colony elects to fight, this must also be roleplayed using the TNE combat rules. In this case, the corsairs will bombard the colony from orbit, killing 1D10×5 colonists and 1D10×5 units of livestock, and destroying 1D10×5 units of capital machinery and 1D20×50 cubic meters of housing before withdrawing. –2 on Political roll.

Slaver: A Far Trader arrives and lands a raiding force to seize colonists for sale in the slave markets of the Wilds. If they resist, the slaver will bombard the colony from orbit doing damage as the corsair above. They will then take 1D6×10 of the colonists as slaves. Any attempts to modify or thwart this result must be roleplayed using the appropriate combat rules. –3 on Political roll.

Warship: A warship from the Wilds arrives (referee's discretion whether it is a vampire, hostile power, mystery ship, etc.). It bombards the colony from orbit destroying 1D6×10% of housing, 1D6×10% of capital machinery, and killing 1D6×30% of the colonists and 1D6×10% of the livestock. The warship is a Close Escort on a roll of 1-4 on 1D6; a Mercenary Cruiser on a roll of 5-6. –3 on Political roll.

Vampire Cruiser: A Vampire Cruiser arrives. On a 2D6 roll of 1-3, the cruiser threatens to destroy the colony unless the colonists provide 1D10×10 replacements to join its crew. If the colonists refuse, the cruiser bombards the colony, causing the damage shown under Warship above. –3 on Political roll.

Native Encounters: NPC colonists have encountered natives. When this result is obtained, roll on the First Encounter table to determine what type and how many natives have been encountered by the colonists. Note from the world map that the former starport and scout base was located on the continent immediately to the west of the proposed island colony site. If the colony is located on this island, roll 1D6 on the table below. If the colony is located on the continent with the former starport, roll 2D6. If located elsewhere on the world, disregard the Native Encounter result.

Once the composition of the native group is established, consult the Interaction section of the Bootstrap Chapter to determine the attitudes of the colonist group and the native group upon meeting.

2D6	*First Encounter*
2	Chieftain
3	Warriors
4	Fishermen
5	Fishermen
6	Warriors
7	Peasants
8	Peasants
9	Fishermen
10	Fishermen
11	Warriors
12	Mounted Warriors

Chieftain: A native chieftain and 3D6 members of his household troops are encountered on an exploration expedition. Their boats are drawn up on the beach nearby.

Warriors: Warriors numbering 3D6 armed with spears and bows are encountered nearing the colony.

Fishermen: 2D6 fishermen are sitting on and near their boats which are drawn up on the beach and are repairing their nets when a group of colonists stumble upon them.

Peasants: 2D6 peasants are encountered by a colonial exploration team tilling their fields. Further investigation will reveal a village with 2D5×10 inhabitants.

Mounted Warriors: A mounted group armed with swords, lances, and composite bows on riding beasts is encountered by a colonial exploration team.

Favorable Government Development: Due to changes in the political situation on Baldur, the colonial program becomes a popular and growing concern. Exports from the colony become highly sought-after. Multiply monthly export monetary value by 1.25

Unfavorable Government Development: Changes in the political situation on Baldur adversely affect the colony, roll 1D6 below.

1	Funding Cut
2	Government Takeover
3	Criminal Charges
4	Colony Terminated
5	Colony Abandoned
6	Hostile Colony Established

Funding Cut: A reallocation of government funding results in a decline to the shipping dedicated for colonial support. Roll 1D10 each month for 4+ to see if shipping arrives to allow the shipping of exports. If no ships arrive, no exports may be made, and no revenue generated. A second result of this event is the same as "Colony Abandoned." –2 on Political roll.

Government Takeover: Political maneuvering on Baldur causes the colonial administration to change its colonial policy and replace the current colony leaders under allegations of incompetence. A warship arrives to return them to Baldur where they are once again unemployed. The players may avoid replacement by succeeding at a legal appeal (Formidable: Admin/Legal). If they fail, they are replaced with inexperienced government lackeys. If they succeed, there is still a –2 DM on the political roll. If they refuse to return, they will be left on their own.

Arrest Warrant: As above, but political maneuvering requires trumped-up charges against the colony leaders to deflect attention from malfeasance elsewhere. A warship and a detachment of Marines arrive with a warrant to arrest the world tamers and return them to Baldur where they are charged with fraud and embezzlement. They are

replaced with inexperienced government lackeys. If they run, they will be hunted by the Marines.

Colony Terminated: A change of governmental priorities results in the abandonment of the colonial program as an unnecessary drain on resources, and shipping is sent to take the colonists home. If PC leaders attempt to convince them to stay, this will require low-level roleplaying, Persuasion tasks, etc., at the referee's discretion. The main criteria should be the current position on the Political Track, with high levels making most colonists favorably inclined to stay, and so on.

Colony Abandoned: A change of governmental priorities results in the abandonment of the colonial program as an unnecessary drain on resources, and the colony is simple abandoned. The shipping which had previously been sent to the colony is cut off, and the colony must now rely on other shipping. Roll 8+ on 1D10 each month for shipping to arrive and allow exports to be shipped. Roll randomly each month to find the world that the cargo will be shipped to, in order to calculate proper exchange rates. Once this result has been obtained, results of 1-5 on this table are treated as no effect. –2 on the Political roll.

Hostile Colony Established: Another colony is established on the world. Source of colony is at referee's discretion, and the two may end up competing for resources or access to export markets, referee's discretion. Alternately, it may be a different type of colony such as a penal colony, or a colony of slaves working a mine.

Native Animal Attack: Native animals attack colonists or their livestock. Roll 1D6. On a roll of 1-3, livestock are attacked. On a roll of 4-5, colonists are attacked. On a roll of 6, one or more player characters are attacked. Use the animal encounter table to logically or randomly determine kind and number of animal attackers. If the attack is by a large number of herbivores, it is a stampede that could damage a large amount of property and kill people and livestock, particularly if the herbivores are large. An attack by a solitary animal would probably be an attack by a pouncer, however, there are other possibilities depending on the attack's circumstances. These are up to the referee.

Minor Crime: Minor crime occurs in the colony, damaging morale to the tune of –1 on the Political roll for the turn. Roll 1D6 to determine the offense for purposes of low-level roleplaying. These are suggestions to help jog the imagination; disregard inappropriate results.

1	Brawl
2	Fight
3	Bribery
4	Petty Theft
5	Custom Violation
6	Insult

Brawl: 2D6 colonists overindulge at a tavern, get into an argument, and a major fist fight breaks out.

Fight: A fist fight breaks out between two colonists on the colony's main street.

Bribery: A colonist attempts to bribe a colonial leader for extra seed grain, a larger meat ration, or other unusual benefit.

Petty Theft: Petty thefts of tools and small valuables begin to occur. At the referee's option, the thefts may be the result of a small native animal attracted to shiny metal objects who takes it back to its nest as a "treasure."

Custom Violation: This occurs only when colonists and natives are interacting. Possible causes include:

Territory: The colonists have settled on native lands considered hereditary property by the local people.

Hunting Rights: The colonists have settled on native hunting lands, disrupting the local game population and threatening the natives with starvation.

Religion: Colonists accidentally defile sacred land or a terrain feature.

Insult: A colonist accidentally insults a native with a minor customs violation. Other possibilities are up to the referee.

Major Crime: Crimes are being committed in the colony, damaging cohesion to the tune of –2 on the Political roll. Roll 1D6 to determine the type for low-level roleplaying purposes; DM+2 if criminals are among involuntary colonists. These are suggestions to help jog the imagination; disregard inappropriate results.

1	Theft
2	Livestock Theft
3	Extortion
4	Robbery
5	Kidnapping
6	Murder

Theft: Seed grain is being stolen. The seed grain thefts may be the result of small vermin eating the grain, or at referee's option a colonist stealing the grain for consumption or later resale. Seed grain theft during the first year is a threat to the survival of the colony and may be a capital offense.

Livestock Theft: The colony's animals begin disappearing. Scouts find one or more badly butchered carcasses several days later. Are native animals responsible or are hungry colonists?

Extortion: Shopkeepers and artisans complain that they are being forced to pay protection money after an arsonist torches a shop. Shopkeepers begin to be beaten at random if they don't pay up.

Robbery: Colonists start being robbed of money and valuables late at night. At the referee's discretion, if farmhouses are located on homesteads, a gang of 1D6 armed raiders rob farmers of their livestock, grain, and tools.

Kidnapping: A colonial professional is kidnapped by an armed gang and is held in a remote hideout for ransom. The characters must organize a search and rescue mission.

Murder: One or more colonists are murdered. Roll 1D6. A single person is murdered in a result of 1–4. 1D6–3 persons are killed in a result of 5–6. The single victim may be the result of a crime of passion or a domestic dispute. The single person may also be killed during a robbery or other crime. Multiple murders may be the result of vicious criminal gangs such as the farmhouse raiders mention under "Robbery." The exact circumstances are up to the referee.

SUBSEQUENT YEARS

Assuming the characters and colony survive the first year and the exports are flowing, the characters will receive their Cr100,000 world tamer fee deposited in the bank of their choice on Baldur. The players now have two choices: resign to return home and collect their fee, or stay on at the colony, let the fee accumulate interest, and collect the 10 percent royalty on the value of shipments to the home world.

Taking the Money

This is a "sure thing" choice if the colony has succeeded in shipping exports. It lets the characters move on to new adventures with a lot of cash in their pockets. It also ends this campaign.

Staying On

If the characters have not made the first shipment by the end of the first year or they like the challenge of life on an untamed wilderness planet and they are leading a thriving colony, they may decide to stay on for additional years.

In these subsequent years, the PCs may wish to delegate routine administrative responsibilities to key NPCs and concentrate their efforts on exploring nearby territory and opening it for settlement. If the world has proven to be hospitable, the colonists will begin to spread out and form new settlements nearby. This can happen in an organized fashion under the control of the original colony or individually as bands of pioneers trek over the horizon seeking their independence from high level PCs' government. How the PCs deal with this can be the substance of a subsequent campaign.

Additional Rewards

There are a number of rewards the players can earn beyond the simple monetary payment discussed above. Successful leaders who stay on may well be given permanent land grants by the Baldur government, and the colony may win eventual membership in the Reformation Coalition. Under these circumstances, PCs may find themselves standing for seats in the RC Assembly of Worlds, to become involved in some truly high-level roleplaying.

Or, with their new-found riches and experience, the PCs may decide to start their own colony world farther out in the Wilds and set themselves up as rulers of an independent power, beholden to none, (or maybe just get killed dead by vampires).

The possibilities are limitless.

RCES Scouting Report
Poyzen System So Skire Subsector (1736/Old Expanses)

NOTES

Poyzen served as a scout base and refueling stop along the So Skire Main during the Third Imperium. However, its heavily tainted atmosphere (believed to be the source of the planet's name) made it a low priority for development compared with other more habitable worlds nearby. Shortly before the Rebellion and subsequent Collapse, the volcanic outgassing that was the source of the taint slowed, then ceased. The sulfuric compound taint has since settled out, and in a rare instance in recorded planetological history, a world's atmosphere has become clean. Poyzen is now a virtually Earth-like virgin garden world, ripe for settlement.

The Poyzen System

Poyzen occupies Orbit 3 around an unnamed G3V primary known only by its sector coordinate designation. It is almost centered in its life zone, giving the world moderate temperatures in its equatorial and temperate regions.

Orbit 0 is contains a sun-blasted chunk of rock less than 500 km in diameter. Orbit 1 has a tidally-locked ball of rock about 3000 km in diameter. Orbit 2 is occupied by a 7000 km desert world with a thin carbon dioxide atmosphere. Orbit 4 contains a small gas giant. Orbit 5 has an ice ball planet consisting of frozen water and ammonia ices along with crystalline formations that make it sparkle like a giant snowball in the starlight. Orbit 6 has a large gas giant, and Orbit 7 a small gas giant.

Poyzen has an airless, rocky moon 2000 kilometers in diameter, orbiting 145,000 kilometers out.

Physical

Now that its atmosphere has cleaned itself up, Poyzen is a garden world in every respect. It has a base surface temperature of 8°C and a temperature range of from +40°C to -69°C. Because of its relatively severe axial tilt of 35°, Poyzen's polar caps melt during their summers and freeze solid during their winters. Poyzen has a 369 day year and days that are 30 hours long. Surface gravity is average at 0.9 G. The atmosphere is surprisingly dense at 2.4 standard atmospheres in pressure with an oxygen concentration of 20 percent. The extreme heating and cooling at the poles leads to frequent violent weather. The dense atmosphere makes high winds extremely dangerous on Poyzen.

Oceans cover 69% of the planet. There are ten small continents fairly evenly distributed around the globe. Four major islands and nine archipelagoes complete the land masses. Much of the land on and near the equator is covered with jungle. Two major volcanic mountain ranges are found on two of the equatorial continents while a large desert occupies the wind shadow on the largest. The balance of the land is relatively open fertile grassland and forest. Note that the two northern continents, the northern-most portion of the western-most continent, and the southern polar continent experience frequent glaciation and severe erosion. Because of the lack of human habitation, none of the continents have been named. Previous surveys have used numbers or Greek letter designations beginning with the western-most continent.

History

Poyzen had a scout base and a class-C starport frequently used as a refueling stop by free traders and other small starships traveling the So Skire main beginning about 570. The world was never settled on a permanent basis. The starport and Scout base was staffed by a 200-person crew on tours of duty from the nearby Scout base on Cobham (So Skire 1835). The starport and Scout base was destroyed by unknown causes during the Collapse. The fate of the staff is unknown. Poyzen is presently believed to be uninhabited.

CHAPTER 8: STARS & PLANETS

STARS

These are generated in accordance with the rules presented on TNE page 192, when not using published pregenerated sectors. These can be generated in advance or on a hex-by-hex basis, allowing the universe to be generated randomly as the campaign proceeds.

PLANETS

Planets are generated according to the system found on pages 192-195 of the TNE rulebook. This generation system provides the standard UWP data for such worlds, but planets that are to be surveyed for potential habitation require a closer level of detail, produced in the following section, "Detailing Planets." For the purposes of a world tamer campaign, survey missions will concentrate on worlds within the habitable zones of star systems, so referees should concentrate on detailing those worlds. Details for the remaining (inner and outer zone) worlds of the system may or may not be required in further adventures.

DETAILING PLANETS

This section provides the level of detail required for world tamer survey, colony, and bootstrap missions. This detail need not be generated for all worlds in a campaign, but only those for which detailed exploration or colonization is intended or likely.

I. Years and Days

Calculating a planet's orbital period around its star, which yields the length of its year in days, and calculating the length of the planetary day is a multi-step procedure. To calculate both, you need to know the mass of the primary star the planet is orbiting, and the distance in kilometers from the primary star.

1. Determine the primary star's mass from the Stellar Mass table by cross indexing the star's spectral type with its luminosity class. The resulting value is in solar masses (Sol = 1).

STELLAR MASS

Spectral Type	*Luminosity Class* II	III	IV	V	D
A0	14	12	6	3.2	0.36
A5	11	9	4	2.1	—
F0	10	8	2.5	1.7	0.42
F5	8.1	5	2	1.3	—
G0	8.1	2.5	1.75	1.04	0.63
G5	10	3.2	2	0.94	—
K0	11	4	2.3	0.825	0.83
K5	14	5	—	0.570	—
M0	16	6.3	—	0.489	1.11
M5	16	7.4	—	0.331	—

2. Determine the distance of the planet's orbit from the central star in AUs using the Orbital Distance table.

ORBITAL DISTANCE

Orbit	*AUs*	*Million Kilometers*
0	0.2	29.9
1	0.4	59.8
2	0.7	104.7
3	1.0	149.6
4	1.6	239.4
5	2.8	418.9
6	5.2	777.9
7	10.0	1495.9
8	19.6	2932.0
9	38.8	5804.0
10	77.2	11,548.0
11	154.0	23,038.0
12	307.6	46,016.0
13	614.8	91,972.0
14	1229.2	183,885.0
15	2548.0	367,711
16	4915.6	735.363.0
17	9830.8	1,470,666.0
18	19,661.2	2,941,274.0
19	39,322.0	5,882,488.0

3. Compute the orbital period using this formula:

$$P = \sqrt{D^3 + M}$$

P= Period in standard years. Multiply by 365.25 to convert to standard days.

D= Distance in AUs. Multiply by 149.6 to covert to millions of kilometers.

M= Mass of central star in solar masses (from the Stellar Masses table).

4. Compute the planet's rotation period in hours using this formula:

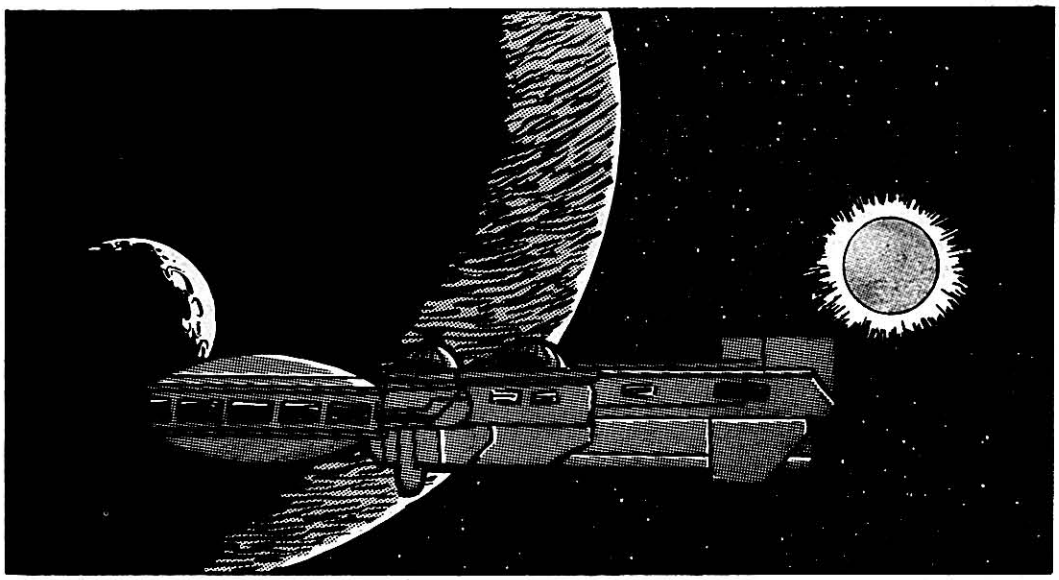
$$P = 4A + 5 + (M+D)$$

P= Rotation period in hours (Divide by 2 to determine the length of the local day and local night at the equator in hours, and divide by 24 to get rotation period in standard days.)

A= Dice Roll 2D6-2.

M= Mass of the central star in solar masses.

D= Distance from the central star in AUs.



If the result is greater than 40, roll 1 D10 for 6+ for the world to be tidally locked. See further discussion below on pages 86 and 90.

If the central star is a K type star roll 1D6. The planet is tidally locked on a result of 4-6.

If the central star is an M type star, and the planet is in the habitable zone, roll 1D6. It is tidally locked on a result of 3-6; if it is in the inner zone it is automatically tidally locked.

5. Determine the planet's orbital eccentricity with the following table. This will be used to compute temperature below.

2D6	*Orbital Eccentricity*
2-7	0.000
8	0.005
9	0.010
10	0.015
11	0.020
12	Roll 1D6 below:
	1 0.025
	2 0.050
	3 0.100
	4 0.200
	5 0.250
	6 extreme (referee's choice)

II. Base Mean Surface Temperature and Variation

Compute the base surface temperature of the world using this formula:

$$T=L\times O\times E\times G$$

T = World's base mean surface temperature (Kelvin; subtract 273 to get Celsius)

L = Luminosity of the primary star (From the Luminosity Table).

O = Orbital factor for the world (from the Orbital Factor Table).

G = Greenhouse effect for the world (from The Greenhouse Effect Table).

E = Energy absorption factor for the world (from the Energy Absorption Table). Within each atmosphere type, the column HZ indicates a world with that atmosphere type in the habitable zone, and the column NHZ indicates a world with that atmosphere type not in the habitable zone (i.e., in the inner or outer zone)

Luminosity

Spectral Type	Luminosity Class II	III	IV	V	D
A0	6.85	4.09	3.53	3.08	0.27
A5	5.40	3.08	2.47	2.00	—

Greenhouse Effect

Atmos Code	Greenhouse Effect	Atmos Code	Greenhouse Effect
0	1.00	7	1.10
1	1.00	8	1.15
2	1.00	9	1.15
3	1.00	D	1.15
4	1.05	E	1.00
5	1.05	F	1.10
6	1.10		

IIa. Effects of Orbital Eccentricity: The eccentricity of the orbit as calculated above will cause higher temperatures at closest approach to the primary star and lower temperatures at farthest separation from the primary star, as follows:

$$Tc = O\times 30$$
$$Tf = O\times -30$$

Tc = Temperature modifier at closest approach

Tf = Temperature modifier at farthest separation

O = Orbital eccentricity

IIb. Effects of Latitude: Determine the temperature modification effects of latitude from the following table; noted in terms of hex rows on the global data view planetary map.

Latitude Temperature Modifiers

Hex Row	UWP Size Digit Size 1	Size 2, 3	Size 4, 5	Size 6, 7	Size 8, 9	Size A
1	+9	+12	+15	+18	+21	+24
2	+6	+8	+10	+12	+14	+16
3	+3	+4	+5	+6	+7	+8
4	0	0	0	0	0	0
5	–3	–4	–5	–6	–7	–8
6	–6	–8	–10	–12	–14	–16
7	–9	–12	–15	–18	–21	–24
8	–12	–16	–20	–24	–28	–32
9	–15	–20	–25	–30	–35	–40
10	–18	–24	–30	–36	–42	–48
11	–21	–28	–35	–42	–49	–56

III. Seasons

A planet's seasons and corresponding variation in temperature depend primarily on its axial tilt. A planet with no tilt has no seasons, rather it has a constant basic climate all year round. A planet with a high degree of tilt has massive temperature variations between seasons and consequent violent weather, as the atmosphere constantly attempts to equalize the extremes between the seasonal hemispheres. To determine the variations between seasons, follow this procedure:

1. Determine the planet's axial tilt. Roll on the Axial Tilt table.

2. If necessary, roll on the Secondary Axial Tilt table.

AXIAL TILT

2D6	*Axial Tilt (in degrees)*
2-3	0° +(2D6-2)°
4-5	10° +(2D6-2)°
6-7	20° +(2d6-2)°
8-9	30° +(2d6-2)°
10-11	40° +(2d6-2)°
12	Use Secondary table

SECONDARY AXIAL TILT

1D6	*Axial Tilt (in degrees)*
1-2	50° +(2D6-2)°
3	60° +(2D6-2)°
4	70° +(2D6-2)°
5	80° +(2D6-2)°
6	90°

3. Use the following formula to determine the maximum increase in base temperature during the planet's summer season.

$$T = 0.6A$$

T = the base temperature increase during the summer.

A = axial tilt in degrees.

4. Use the following formula to determine the maximum decrease in base temperature during the planet's winter season.

$$T = A$$

T = the base temperature decrease during the winter.

A = axial tilt in degrees.

5. The above base seasonal temperature changes are modified by latitude as shown on the table below, where latitude is noted as the hex row on the global data view planetary map. For example, in hex row 5 on a world with an axial tilt of 28 degrees, these base temperature changes would be multiplied by 0.75.

IV. Day/Night Temperature Variation

First compute the length of daytime or nighttime by dividing the world's rotational period by 2. Then compute the rotation-luminosity factor R with the following formula:

$$R = L + \sqrt{D}$$

R = Rotation-luminosity factor

L = Luminosity of the primary star as used in the base temperature step above

D = Distance from the primary star in AUs as found on the Orbital Distance table on page 83

The value R is then used to calculate the daytime temperature increase and nighttime temperature decrease below.

Daytime Temperature Increase: The average temperature increase during the world's day is computed based on R above and the length of the local day in hours (as on Daytime Temp Increase table). The plus temp may never exceed the absolute maximum plus temperature.

Nighttime Temperature Decrease: The average temperature decrease during the world's night is computed based on the length of the local night in hours. Minus temp per hour of night is in Celsius degrees (as on Nighttime Temp Decrease table). The minus temp may never exceed the absolute maximum minus temperature.

DAYTIME TEMP INCREASE

UWP Atm Digit	*+Temp per hour of Daylight*	*Absolute Maximum +Temp*
0	1.0×R	0.1×Max
1	0.9×R	0.3×Max
2, 3, E	0.8×R	0.8×Max
4, 5	0.6×R	1.5×Max
6, 7	0.5×R	2.5×Max
8, 9	0.4×R	4.0×Max
D, F	0.2×R	5.0×Max

NIGHTTIME TEMP DECREASE

UWP Atm Digit	*–Temp per hour of Night*	*Absolute Maximum –Temp*
0	20.0 C	0.80×Base
1	15.0 C	0.70×Base
2, 3, E	8.0 C	0.50×Base
4, 5	3.0 C	0.30×Base
6, 7	1.0 C	0.15×Base
8, 9	0.5 C	0.10×Base
D, F	0.2 C	0.05×Base

Max : the Base Mean Surface Temperature (Kelvin) as calculated earlier × R

Base : the Base Mean Surface Temperature (Kelvin) as calculated earlier

V. Axial Tilt Effects

	Degree of Axial Tilt											
Hex Row	*0*	*1-5*	*6-10*	*11-15*	*16-20*	*21-25*	*26-30*	*31-35*	*36-45*	*46-60*	*61-84*	*85+*
1	0.00	0.00	0.00	0.00	0.00	0.00	0.00	0.00	0.25	0.50	0.75	1.00
2	0.00	0.00	0.00	0.00	0.00	0.00	0.00	0.25	0.50	0.75	1.00	1.00

9	0.00	0.25	0.75	1.00	1.00	1.00	1.00	1.00	1.00	1.00	1.00	1.00
10	0.00	0.50	1.00	1.00	1.00	1.00	1.00	1.00	1.00	1.00	1.00	1.00
11	0.25	1.00	1.00	1.00	1.00	1.00	1.00	1.00	1.00	1.00	1.00	1.00

VI. Temperature Worksheet

Creation of a temperature worksheet as follows allows rapid consultation of maximum and minimum temperatures for all planetary hex rows.

Note that column 3 shows the base temperature for all hex rows in Celsius degrees, column 9 shows the highest possible temperature for each hex row (Celsius), and column 15 shows the lowest possible temperature for all hex rows (Celsius).

The upper worksheet may be photocopied by owners of this book to assist in detailing their own worlds.

The lower worksheet is a sample, filled out for a UWP size 8 world with a dense atmosphere, 26° axial tilt, 25 hour rotational period, and orbital eccentricity of 0.020. The temperature values used are: base temperature of 9°C, summer plus of 16°C, winter minus of 26°C, daytime plus of 5°C, nighttime minus of 7°C, and orbital eccentricity plus/minus of 1°C.

				Highest Possible Temp						Lowest Possible Temp

VII. Temperature on Tidally Locked Planets

Worlds which are tidally locked to their primary stars have their temperatures computed differently.

The base temperature applies to the twilight region between the world's light and dark side, rather than hex row 4. By convention, the twilight region is in hex row 1 on the map (both rows on either side of the equator). Also by convention, the top hexrows are the permanent dayside, and the bottom hexrows are the permanent nightside.

Use the maximum plus for the daytime plus, since daytime is effectively infinite.

To determine the latitude mod per hexrow on the dayside, divide the daytime plus by the world's UWP size digit (but the dayside plus temperature must never exceed the maximum daytime plus in any hex row, however).

Use the maximum minus for the nighttime minus, since nighttime is effectively infinite.

To determine the latitude mod per hexrow on the nightside, divide the nighttime minus by the world's UWP size digit (but the nightside temperature minus must never exceed the maximum nighttime minus in any hex row, however).

Axial tilt has no effect, as the world does not rotate.

Orbital eccentricity works normally.

VIII. Density & Gravity

Use these tables to determine the density of the planet, and from that information, the planet's surface gravity.

World Density

1D6	Density
1	Low
2-4	Average
5-6	High

DMs: -2 if the world is in the outer zone. Modified rolls of less than 1 are treated as 1.

Density Equivalent

Density	Density Equivalent in Earths (Terra = 1)
Low	.55
Average	1.0
High	1.55

IX. World Mass

If the planet has a satellite, the world's mass must be calculated in order to calculate the satellite's orbital period. To determine world mass, use this formula.

$$M=K\times(R+8)^3$$

M= Mass in standard masses (Terra = 1)
K= Planet's density in Earths (see Density Equivalent table).
R= UWP size digit (use 0.6 for size S).

World Gravity

	Density		
Diameter	Low	Average	High
1600 (1)	.10	.15	0.3
3200 (2)	.15	.25	0.5
4800 (3)	.30	.40	0.8
6400 (4)	.35	.50	1.0
8000 (5)	.45	.60	1.2
9600 (6)	.55	.80	1.6
11,200 (7)	.60	.90	1.8
12,800 (8)	.70	1.0	2.0
14,400 (9)	.70	1.1	2.2
16,000 (A)	.80	1.3	2.6

Satellites

Many planets will have satellites, and some gas giants located in the habitable zone will have satellites that are habitable and which can serve as the main world of a system. The presence and characteristics of satellites are determined using the procedures in **TNE**, pages 194-195.

Orbital Period: To determine the orbital period of a satellite around its central planet, follow this procedure:

1. Multiply the planet's radius (half the diameter listed in the UWP World Size table on Page 188 of **TNE**) by the orbit number (**TNE** page 195) to calculate the satellite's distance from its planet in kilometers.
2. Calculate the mass of the central planet as described in the previous section.
3. Use the following formula to compute the orbital period:

$$P=\sqrt{([D+400{,}000]^3\times 793.64)+M}$$

P= Period in standard days
D= Distance in kilometers
M= Mass of central planet in standard masses

Satellite Rotation Period: Compute the satellite's rotation period in hours using this formula:

$$P = (4A) + 5 + (M+D)$$

P= Rotation period in hours (Divide by 2 to determine the length of the local day and local night at the equator in hours, and divide by 24 to get rotation period in standard days.)
A= Dice Roll 2D6-2
M= Mass of the planet in standard masses
D= Distance from the planet in kilometers divided by 400,000

If the result is greater than 40, the satellite is tidally locked to its central world on a 1D10 roll of 6+.

MAPPING A WORLD

This section describes how to draw a map based on the detailed data generated so far. **Traveller** uses a hex grid in the form of a flattened icosahedron (a 20-sided solid the same shape as 20-sided die) for mapping the surface of a world. The map is divided into 20 interlocking triangles of 25 hexes each, totaling 500 hexes per map. These hexes are called "planetary hexes." The equator is 35 planetary hexes long. Blank copies of this standard map format, called the "global data view," are available in the **Traveller Players' Forms** book.

Note that the following material is presented as guidelines only. As such, they are intended to be aids to creativity, and not boundaries upon it. Within the parameters of the previously generated UWP data, referees and world designers should feel free to create world maps using whatever methods are comfortable for them.

Planetary Hex Size

The Survey chapter of this book contains a discussion of planetary hexes and their relationship to 20-kilometer mapping hexes as used in the Survey, Colony, and Bootstrap chapters. Page 20 contains a table showing the dimensions of planetary hexes for each of the UWP world sizes. Note that these figures are based on the average world diameter for that UWP size, not the entire possible range. (For example, a UWP size code of 8 indicates worlds whose diameters range from 12,000 km to 13,599 km, with an average diameter of 12,800 km. See TNE page 188 for more details.)

For conversion to 20-km mapping hexes, it is best to stick with the average diameter figure which is used on the page 20 table. For those who prefer to know the exact actual size of each hex based on the world's actual diameter, use the following procedure.

1. Calculate the circumference of the world by multiplying its diameter in kilometers by 3.1416.
2. Divide the resulting circumference by 35.

This is the width (between opposite hexsides) of the planetary hex.

Tectonic Plates

Multiple tectonic plates occur on worlds with average and high densities (low density worlds have only a single tectonic plate). Multiple plates are the solid world crust floating atop the planet's molten mantle, and separated by fault zones. They may be converging, traversing, or diverging.

Converging tectonic plates cause heavy seismic activity and build mountains as they collide.

Traversing plates are relatively stable, but slide against each other causing seismic activity.

Diverging plates are separating, creating vast trenches in the planet's crust.

Number of Plates: To calculate the number of tectonic plates on a planet:

Add the world's UWP size and UWP hydrosphere digits and subtract 2D6.

Note that it is possible for world to have only one tectonic plate (as is already the case with low density worlds). This world would have little or no seismic activity.

Tectonic Plate Size	
1D6	*Size in Hexes*
1	2D×5
2	2D×10
3	2D×15
4	2D×20
5	2D×25
6	2D×30

Size of Plates: For mapping purposes, calculate the number of hexes per tectonic plate. To do this, roll 1D6 on the Tectonic Plate Size table

By default, the last tectonic plate placed is the largest, and is always as large as the remaining number of hexes on the world map grid. Exact placement of the plates is up to the referee or world designer. Sketch them lightly in pencil on the map grid; they won't appear on the final map, but they'll be useful in determining the layout of continents and oceans, establishing seismic effects, and locating some terrain features.

Plate Movement: For each plate boundary, roll on the table at the right to determine plate movement.

Tectonic Plate Movement	
2D6	*Movement*
2	Converging
3	Converging
4	Converging
5	Converging
6	Traversing
7	Traversing
8	Traversing
9	Diverging
10	Diverging
11	Diverging
12	Diverging

Continents & Oceans

Once the tectonic plates are located, the designer can begin outlining continents and oceans. This depends on the planet's UWP hydrographic code. If it is 5 or less, map oceans first, and all leftover hexes will be land masses. If it is 6 or greater, map continents first, with all leftover hexes becoming oceans and other bodies of water. If no water is present (code 0), go directly to determining terrain.

Mapping Water Hexes

First calculate the actual hydrographic percentage. See the World Hydrographics table on **TNE** page 188 to see the minimum and maximum hydrographic percentage for each code. For example, a digit of 4 indicates a value between 35 and 44 percent. Use 1D10 to find the exact number in this range by adding the 1D10 result to the minimum number, and treating results of "10" as "0."

To calculate the total number of water hexes on the planet, multiply the actual hydrographic percentage by 5. Thus a world with a hydrographic percentage of 42% has 210 water hexes out of 500 total hexes.

To calculate the number of land hexes, subtract the water hexes from 500. Our sample world has 290 land hexes (500-210 = 290).

If the planet has 49% or less water, determine exactly how many lakes, seas and oceans are present. To do this:

1. Multiply the planet's UWP hydrographic code by 3.
2. Roll 1D6 and add the result to the result in step 1.
3. Compare the result to the Oceans Table.

Oceans			
Result	*Major Oceans*	*Minor Oceans*	*Other Bodies of Water*
1	0	0	No Significant Water Surface
2	0	0	No Significant Water Surface
3	0	0	Scattered Lakes
4	0	0	Scattered Lakes
5	0	0	1D6-3 Small seas, 2D6 scattered lakes
6	0	0	2D6-3 Small seas, 2D6 scattered lakes
7	1D6-4	1D6-3	3D6-3 Small seas, 2D6 scattered lakes
9	1D6-3	1D6-2	3D6-3 Small seas, 2D6 scattered lakes
10	1D6-3	1D6-1	3D6-3 Small seas, 2D6 scattered lakes
11	1D6-2	1D6-1	3D6-3 Small seas, 2D6 scattered lakes
12	1D6-2	2D6-2	3D6-3 Small seas, 2D6 scattered lakes
13	1D6-1	1D6-1	3D6-3 Small seas, 2D6 scattered lakes
14	1D6-1	2D6-2	3D6-3 Small seas, 2D6 scattered lakes
15	1D6-1	3D6-3	3D6-3 Small seas, 2D6 scattered lakes
16	1D6	2D6-2	3D6-3 Small seas, 2D6 scattered lakes
17	1D6	3D6-3	3D6-3 Small seas, 2D6 scattered lakes
18	1D6	1D6-1	3D6-3 Small seas, 2D6 scattered lakes
19	1	1D6-1	3D6-3 Small seas, 2D6 scattered lakes
20	1	2D6-2	3D6-3 Small seas, 2D6 scattered lakes
21	1	3D6-3	3D6-3 Small seas, 2D6 scattered lakes

Scattered Lakes: Scattered lakes are very small bodies of water; a hex containing scattered lakes is considered to be 1/2 of a hex of water surface. Determine the location of scattered lakes before placing other bodies of water. Divide the number of scattered lakes by two and subtract that valve from the water hex total.

Small Sea: Small seas cover roughly one hex of water surface. The number of small seas is in the Oceans Table "Other Bodies of Water Column." Deduct the small sea hexes from the water hex total before determining the size of major and minor oceans.

Major Oceans: A major ocean is a body of water that covers 15% or more of the world's water surface area. As an example, if a world has 160 water hexes, each major ocean must cover at least 24 hexes. If there is only one major ocean, it will include almost all of the planet's water surface area.

Minor Oceans: Any water surface area left after major oceans are placed is divided into minor oceans. A minor ocean covers less than 15% of the planet's water surface area.

Any body of water can have major islands (1 hex) and archipelagoes (1/2 hex).

Mapping Land Hexes

If the actual hydrographic percentage of a world is between 50 and 100%, map the land hexes first. The remaining hexes are water hexes. If the hydrographic percentage is 100%, any land will be incidental islands.

To calculate the number of land hexes, subtract the water hexes from 500.

If the planet has 51% or more water, determine exactly how many major and minor continents and islands are present. To do this:

1. Multiply the planet's UWP hydrographic code by 3.
2. Roll 1D6 and add the result to the result in step 1.
3. Compare the result to the Continents Table.

CONTINENTS

Result	Major Continents	Minor Continents	Other Land Masses
16	2D6+1	1D6-1	3D6-3 Major Islands, 2D6 Archipelagoes
17	2D6+1	2D6-2	3D6-3 Major Islands, 2D6 Archipelagoes
18	2D6+1	3D6-3	3D6-3 Major Islands, 2D6 Archipelagoes
19	2D6	1D6-1	3D6-3 Major Islands, 2D6 Archipelagoes
20	2D6	2D6-2	3D6-3 Major Islands, 2D6 Archipelagoes
21	2D6	3D6-3	3D6-3 Major Islands, 2D6 Archipelagoes
22	1D6	1D6-1	3D6-3 Major Islands, 2D6 Archipelagoes
23	1D6	2D6-2	3D6-3 Major Islands, 2D6 Archipelagoes
24	1D6	3D6-3	3D6-3 Major Islands, 2D6 Archipelagoes
25	1D6-1	1D6	3D6-3 Major Islands, 2D6 Archipelagoes
26	1D6-1	2D6	3D6-3 Major Islands, 2D6 Archipelagoes
27	1D6-1	3D6	3D6-3 Major Islands, 2D6 Archipelagoes
28	1D6-2	1D6-1	3D6-3 Major Islands, 2D6 Archipelagoes
29	1D6-3	1D6-2	3D6-3 Major Islands, 2D6 Archipelagoes
30	1D6-4	1D6-3	2D6 Major Islands, 2D6 Archipelagoes
31	0	0	1D6-3 Major Islands, 2D6 Archipelagoes
32	0	0	Archipelagoes
33	0	0	Archipelagoes
34	0	0	Archipelagoes
35	0	0	No significant land surface
36	0	0	No significant land surface

Archipelagoes: Archipelagoes are groupings of small islands, considered to be 1/2 of a hex of land surface. Archipelagoes are placed prior to major islands and larger land masses. Divide the number of archipelago hexes by 2 and subtract the result from the total number of land hexes.

Major Islands: Major islands are land areas covering roughly one hex. The "Other Land Masses" column on the Continents Table indicates how many major island hexes are present on a world. Deduct the number of major island hexes from the total number of land hexes before determining the size of major or minor continents.

Major Continents: A major continent covers at least 15% of the land surface area of a world. The Terran equivalents of major continents are Eurasia (37%), Africa (20%), and North America (16%). The other continents are minor continents.

Minor Continents: Any land surface remaining after major continents have been placed are divided up between minor continents. A minor continent covers less than 15% of the world's land surface.

Note that any land mass can have land-locked small seas (1 water hex each) and scattered lakes (1/2 water hex each).

Placement

Next, place the land and water bodies determined above, using the tectonic plates as guides. When placing continents, divide them up as evenly as possible among the tectonic plates. Ideally, there should be one continent per plate. Plates may also underlie oceans. Plates overlap when there is more than one plate per continent, or when a continental plate lies next to an oceanic plate. These are active seismic zones.

Continents separated by only one hex may be joined by a narrow strip of land called an isthmus. Likewise, oceans only one hex apart may be joined by a strait. Decide these options either by personal preference or with a random die roll (9 or above on 2D6 indicating the presence of an isthmus or strait).

Terrain

Once the land masses are placed, it is time to map the planet's terrain. This includes surface feature terrain such as ice caps, tundra, steppes, mountains, badlands, and open terrain; life influenced terrain including deserts, jungles, and forests; and terrain affected by civilization: cities and farmlands.

Ice Caps: These are frozen wastes covered with ice. To determine how far from the poles ice caps extend and where tundra is located, use the axial tilt and temperature determination procedure in the "Seasons" section of this chapter. The temperatures generated by this procedure will indicate how many hex bands from each pole have below 0° Celsius freezing conditions all year round.

Tundra: Tundra is marshy, semi-frozen open terrain located usually within one hex next to the polar icecaps (if any).

Steppes: Steppes are open grasslands with very few trees, if any. Steppes may be placed anywhere except in the polar regions or in coastal hexes.

Mountains: Mountains are created by plate tectonics. Place mountain ranges along tectonic plate boundaries on land hexes. Mountain ranges are represented by two or more contiguous mountain hexsides. (Island chains—which are the tops of mountains rising from the seabed—may be placed along undersea tectonic plate boundaries.)

Badlands: Badlands occur next to mountain hexsides, much like tundra occurring next to ice caps. This is rugged, high terrain with broken ground, gullies and cliffs.

Deserts: There are three types of desert:

Continental Deserts: Continental deserts are placed on any continent where ten or more contiguous, non-tundra, non-badland hexes are present and a 2D6 dice throw of greater than or equal to the planet's UWP code is made. If a desert result occurs, roll 2D6-1 for the number of desert hexes present. When only one continent is present, check once per map triangle with 10 or more contiguous open hexes.

Wind Shadow Deserts: Wind shadow deserts occur because mountain barriers block movement of moisture in the atmosphere. There are wind shadow desert hexes equal to the planet's UWP hydrographic code–1D6. Place them next to mountain or badlands hexes.

Coastal Deserts: Coastal deserts occur because prevailing winds blow moisture out to sea. There are coastal desert hexes equal to the planet's UWP hydrographic code -2D6. They may be placed in any coastal hex within four hexes of the polar caps.

All desert terrain is dry and supports very little to no life.

Jungles: Jungle hexes are placed in regions where temperatures range between 20° and 40° Celsius. If a group of 10 contiguous, non-desert, non-badlands hexes exist on a continent with this temperature range, and a throw of less than or equal to the UWP hydrographic code is made on 2D6, a jungle is present. Islands and archipelagoes may also have jungle terrain. Roll 2D6-1 for the number of island jungle hexes. Jungle hexes must be within three hexes of an ocean or sea. They may not be next to desert hexes.

Jungles teem with life, but are difficult to cultivate or travel through.

Mixed: All remaining hexes are mixed hexes. These are forested if in a wild state, or cultivated farmland if settled. Cities and other settlements are generally located in mixed terrain hexes, usually along rivers or on seacoasts for access to transportation or to a water supply.

Starports: Starports are usually located in mixed terrain, on or near the equator. The equatorial location enables departing ships to take advantage of the planet's rotational velocity at liftoff.

Tidally Locked Worlds

A tidally locked world always has one hemisphere facing its primary star in perpetual daylight and the other facing away in perpetual night. Habitable regions are generally located in the twilight band between the center of the hot hemisphere and the center of the cold hemisphere.

When mapping a tidally locked world, designate the top of the map grid as the starward side or "hot pole" and the bottom of the grid as the nightside or "cold pole." The equator becomes the twilight band where most inhabitants live.

The world's hottest temperature is located at the hot pole, and the coldest temperature at the cold pole. The base surface temperature is found in the center of the twilight band, where the primary star perpetually lingers on the horizon.

Ice sheets cover the cold pole while sun-baked deserts cover the hot side. Any oceans would be found near the equator, fed by drainage from the melting cold polar cap.

ATMOSPHERIC COMPOSITION

This section is intended as an optional tool for referees who wish to add specific detail to **Traveller** worlds. It is not intended as a substitute for the standard UWP atmosphere guidelines discussed elsewhere in this book (Chapter 3, Survey) or in other **Traveller** products.

The mix of gases that make up a world's atmosphere depends on their molecular weight and the minimum molecular weight retained by the world's gravity. The Minimum Molecular Weight Retained table shown here contains values for Low, Average, and High Density worlds with UWP sizes ranging from 1 to A. Note that this density refers to the density of the planetary body, not the planet's atmosphere.

MINIMUM MOLECULAR WEIGHT RETAINED

UWP	*Low Density*	*Average Density*	*High Density*
1	vac	vac	vac
2	vac	vac	90
3	91	45	32
4	63	31	22
5	35	17	12
6	28	14	10
7	18	9	6
8	13	6	4
9	11	5	3
A	8	3	1

Compare the minimum molecular weight retained figure with the molecular weight of gases shown in the Molecular Weight of Gases table. The world's atmosphere will retain gases which have a molecular weight of at least the figure shown for the world's UWP size figure and density. As an example, an average density UWP size 8 world will retain gases in its atmosphere with a molecular weight of 6 or higher.

MOLECULAR WEIGHT OF GASES

Constituent	*Molecular Weight*
Molecular Hydrogen (H_2)	2.00
Helium (He)	4.00
Methane (CH_4)	16.00
Ammonia (NH_3)	17.00
Water Vapor (H_2O)	18.00
Neon (Ne)	20.20
Molecular Nitrogen (N_2)	28.00
Carbon Monoxide (CO)	28.00
Nitric Oxide (NO)	30.00
Molecular Oxygen (O_2)	32.00
Hydrogen Sulfide (H_2S)	34.10
Argon (Ar)	39.00
Carbon Dioxide (CO_2)	44.00
Nitrous Oxide (N_2O)	44.00
Nitrogen Dioxide (NO_2)	46.00
Ozone (O_3)	48.00
Sulfur Dioxide (SO_2)	64.10
Sulfur Trioxide (SO_3)	80.10
Krypton (Kr)	83.80
Xenon (Xe)	131.30

Notes on Selected Atmospheric Gases

Ammonia (NH_3): An irritant gas, ammonia requires protective measures even in mild concentrations. Unlike methane, ammonia has a sharp, pungent odor, and leaks are quickly noticed.

Worlds with ammonia are much like those with methane: large, cold, and with standard to very dense pressure. Ammonia is postulated as an alternative to oxygen as a life-supporting gas.

Carbon Dioxide (CO_2): A non-irritant gas, CO_2 occurs commonly, either by itself or in various combinations. Worlds with carbon dioxide in the atmosphere may be in the early stages of developing carbon-based life (although within a few hundred million years the atmosphere will have changed completely). On the other hand, the local life may be evolving in a totally alien direction.

Carbon dioxide atmospheres have the property of trapping heat, causing a greenhouse effect, which may force the world's temperature far above the range in which humans can survive without protective equipment. A runaway greenhouse effect can turn a world into a hostile inferno, and thus be rated as a corrosive or insidious atmosphere.

Hydrogen (H_2): A non-irritant gas, hydrogen is not poisonous. However, like methane, hydrogen combines explosively with oxygen. A spark can cause an explosion, followed by the precipitation of water, the product of the combination of these two elements. Hydrogen will make up a significant proportion of the atmosphere on large, cold worlds, and is often found in combination with methane and ammonia.

The smallest and lightest of atoms, hydrogen poses a special problem that can require an atmosphere containing any significant amount of it to be rated insidious. The atoms are so small that they can seep right through fabrics, plastics, and even solid metal in a process called diffusion. An airtight seal is not necessarily hydrogen-tight. Starship hulls and the walls of buildings can be sealed against hydrogen leakage; vac suits, however, cannot.

Methane (CH_4): A non-irritant gas, methane (also known as "natural gas") is dangerous if mixed at a low (7-14%) concentration with a standard oxygen-nitrogen atmosphere. Any spark can cause the methane to explode and burn fiercely. This can pose a hazard to adventurers if methane leaks into their habitat, space ship, or vac suit. Pure methane is an odorless, colorless gas, making detection almost impossible.

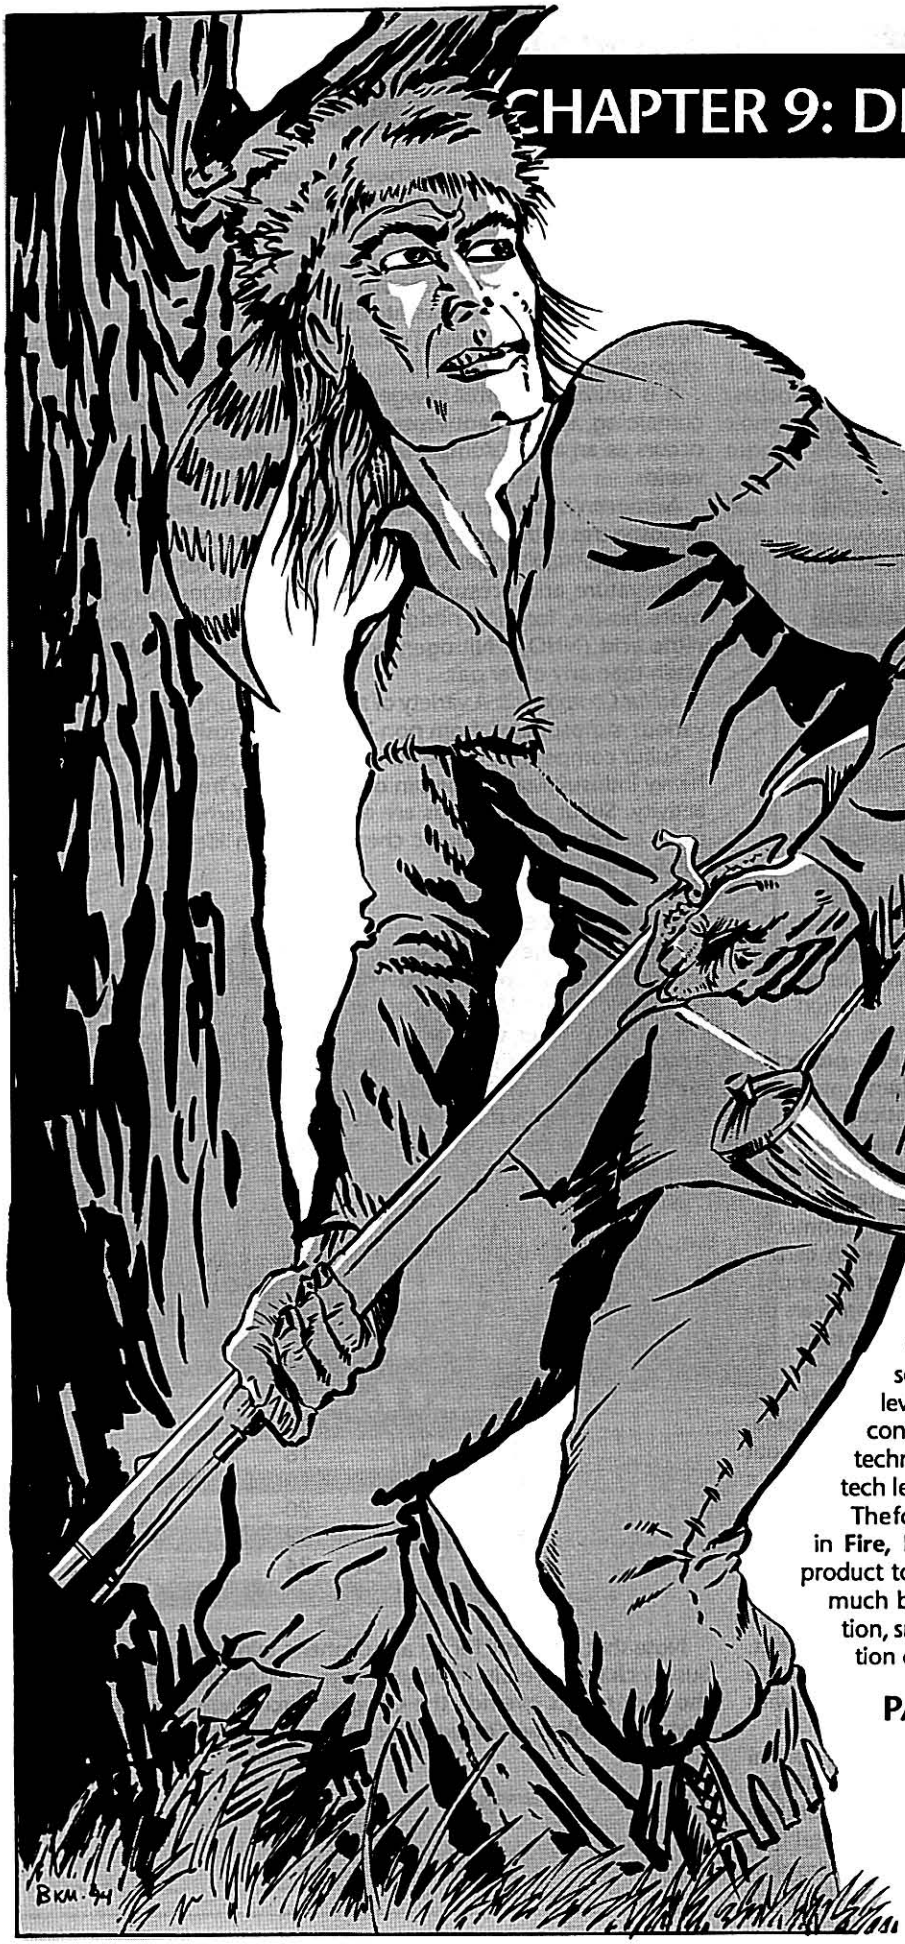
It is unlikely that free oxygen will be found in an atmosphere containing a significant amount of methane. Methane generally occurs as an active component of the atmosphere on large, cold worlds.

Nitrogen (N_2): a semi-irritant gas, nitrogen is relatively inert in atmospheres with standard temperatures and pressures. If nitrogen and oxygen are present in an atmosphere with more extreme temperature and pressure conditions, the atmosphere becomes more hostile, forming nitrides (nitrogen-oxygen compounds) or nitric acid (NHO_3). Nitrogen occurs in world atmospheres more often than any other gas.

Sulfur Compounds: A variety of sulfur compounds can be found in various atmospheres, from non-irritant to corrosive.

Sulfur compounds in the atmosphere can result from prolonged heavy industrialization, or can occur naturally from heavy volcanic activity. Sulfur compounds are a possible alternative to the more usual carbon-based organic chemistry. Such life forms would be totally alien.

Oxygen Percentage



The percentage of free oxygen in a planet's atmosphere depends on the percentage of water covering the world. For purposes of this rule, worlds with a UWP atmosphere code of 0-9 have hydrospheres consisting of water, while worlds with atmosphere codes of A-C have hydrospheres consisting of fluids other than oxygen (and, by definition, do not themselves consist of oxygen in any case). The Oxygen Percentage table shows the percentage of free oxygen in a world's atmosphere based on its UWP hydrographic code.

OXYGEN PERCENTAGE

UWP Hydrographic Code	*Percentage of Free Oxygen*
0	5
1	10
2	12
3	14
4	16
5	18
6	19
7	20
8	22
9	24
A	26

Note that if the roll for an atmospheric taint (see page 16 of the Survey chapter) results in either a high oxygen or low oxygen taint, the taint results override the Oxygen Percentage table, indicating that some unknown external factors have caused this taint.

CHAPTER 9: DESIGN SEQUENCES

BLACK POWDER FIREARM DESIGN

This design sequence is aimed at designing "primitive" firearms, by which we mean weapons firing black powder ammunition. This ammunition consists solely of a bullet and a quantity of black powder. Sometimes the ammunition is included in complete cartridges, wrapped in paper, while at other times the bullets and loose powder are carried and loaded separately.

Due to the tremendous variety of weapons available in a relatively narrow technological band, the following rules make reference to tech levels 2M and 3M ("mature TL-2" and "mature TL-3", where TL-2M is more advanced than TL-2 but not as good as TL-3, and TL-3M is better than TL-3 but not as good as TL-4). The items available at these tech levels represent more mature versions of weapons used at the main tech levels. All tech level 3 weapons designed using the standard design sequence in **Fire, Fusion & Steel** (including tech level 3 brass cartridge ammunition) should be considered 3M technology. Whether or not mature technology items are available on a world or at a given tech level is entirely up to the referee.

The following design sequence parallels that provided in **Fire, Fusion and Steel**, but does not require that product to use. As classic firearms are defined almost as much by their ammunition as by their own construction, small arms design consists of two parts: ammunition design and weapon design.

PART I: Ammunition Design

Ammunition is defined by five characteristics: the tech level, the diameter of the bullet in millimeters (also refered to as caliber), the type of the bullet (spherical, conical, or shot), the length of the cartridge in millimeters, and the type of cartridge (paper or loose powder).

Tech Level: Black powder small arms are available at tech levels 2 and 3. By tech level 4 virtually all firearms use smokeless powder and fixed metallic cartridge cases.

Bullet: The diameter of the bullet in millimeters is called its caliber, and weapons are commonly referred to by their caliber, such as 18mm. Although standard weapons listed in the game are usually in increments of 0.5 millimeters (such as 5.5mm, 7.5mm, etc.) weapons may be designed in any caliber desired, such as 11.43mm or 4.71mm. Small arms may be made in any caliber up 20mm. (Weapons of 20mm and above are usually considered to be cannons.)

Bullet Type: Spherical bullets and shot are available at tech level 2. Conical bullets are available at tech level 3M. Prior to the adoption of conical bullets, rifles fire "patched spherical bullets," which are bullets wrapped in a leather patch to insure a tight fit in the barrel.

If the bullet type is shot (a shotgun shell) the number of bullets in the shell must be specified at this time. The number of bullets must be a multiple of 4.

Cartridge Length: The length of the cartridge is a means of defining how much powder is used to propell the bullet, and is the actual length of the barrel cavity in millimeters filled with powder when the weapon is loaded. The longer the cartridge, the more propellant is contained in it and therefore the more powerful the ammunition.

Ammunition is often referred to by two numbers, the caliber followed by the cartridge length, which helps distinguish it from other ammunition of the came caliber. In the case of shotgun shells the length includes the container for the bullets as well, and so 12 gauge shotgun shells (the most common current shotgun round) is also called 18.5x70mm round, even though the powder cartridge is much shorter than 70mm.

Cartridge Type: For our purposes there are two types of black powder cartridges: loose and paper. Loose cartridges are actually separately carried bullets and powder (often in a powder horn). Paper cartridges include both a bullet and a pre-measured amount of powder all wrapped in paper and sealed against moisure using either wax or grease.

Ammunition Evaluation

Once the ammunition round has been designed, determine its length, weight, magazine weight, and average muzzle energy.

Length: The ammunition length is determined using the following formulae:

Lab = Lc + d
Lac = Lc + 2d
Lasg = Lc

Lab: Length (in millimeters) of spherical bullet ("ball").
Lac: Length (in millimeters) of conical bullet.
Lasg: Length (in millimeters) of shotgun ammunition.
Lc: Length (in millimeters) of the cartridge.
d: Diameter (in millimeters) of the bullet.

Weight: The ammunition weight is determined using the following formula:

$Wa = AwmLc\pi r^2$

r: Radius (in millimeters) of the bullet (half the diameter).
π: 3.1416
Wa: Weight (in grams) of a complete round of ammunition.
Lc: Length (in millimeters) of the cartridge.
Awm: Ammunition weight multiplier, which depends on the bullet type, as shown below.

Ammo Type	*Awm*
Shotgun shell	0.003
Spherical ball	0.003
Conical bullet	0.005

Average Muzzle Energy: The average muzzle energy of ammunition is determined using the following formula. (The actual muzzle energy will be affected by the design of the weapon itself.)

$Ea = TmCmLc\pi r^2$

Ea: Average muzzle energy (in joules) of a cartridge.
Lc: Length (in millimeters) of the cartridge.
r: Radius (in millimeters) of the bullet (half the diameter).
π: 3.1416.
Tm: Tech Level Modifier, as shown on the table below.
Cm: Cartridge modifier, as shown on the table below.

CARTRIDGE MODIFIER

Cartridge Type	*Cm*
Shotgun	0.2
Spherical Ball	0.15
Patched Spherical Ball	0.225
Conical Bullet	0.3

TECH LEVEL MODIFIER

TL	*Tm*
2	0.5
3	0.6

Price: The price of the ammunition is determined by the following formula:

Cr = WTm

Cr: Price in credits.
W: Weight of the round in grams.
Tm: Type multiplier, as determined below:

Type	*Tm*
Shotgun	0.01
Loose Powder	0.005
Paper cartridge (TL-2)	0.05
Paper cartridge (TL-3)	0.01

PART II: Weapon Design

1. BARREL

The barrel of a firearm carries the bullet after the cartridge is fired. Shotguns and muskets, intended for very short ranges, fire their bullets through a smooth bore. Beginning at tech level 3 the barrel is often rifled to impart a spin on the bullet, giving it stability (and thus accuracy) in flight. In addition, the barrel provides a gas-tight constricted space within which the expanding gas of the exploded propellant can act on the bullet, accelerating it. Once the bullet leaves the muzzle of the barrel, however, it begins decelerating. In general, the longer the barrel the higher the muzzle velocity, up to the point where the bullet reaches its greatest possible velocity.

Average Barrel Length: First, determine the average barrel length for the ammunition being used by the weapon. The following formula is used:

$Bla = (Ea+d^2)Rm$

Bla: Average barrel length (in centimeters) - the length of the barrel which allows the ammunition to achieve its average muzzle energy.
Ea: Average muzzle energy (in joules) of the ammunition.
d: diameter (in millimeters) of the bullet.
Rm: Rifling multiplier, as shown below:

Type	*Rm*
Smoothbore	20
Rifled	5

Note 1: Regardless of the results of the above calculations, average barrel length is never less than 10cm.

Note 2: If using **Fire, Fusion, and Steel**, the normal table for rifling multiplier is used, but an additional multiplier of x5 is added for black powder weapons.

Actual Barrel Length: The actual barrel length can be any length desired down to a minimum of 20% of the average barrel length and up to a maximum of 230% of the average barrel length.

Type of Barrel: Barrels may be either light or heavy. All black

powder weapons use heavy barrels except for shotguns, which use light barrels. Weapons other than shotguns may either be rifled or smoothbore. (All shotguns are smoothbores.) Rifled barrels are not available until tech level 3.

Barrel Weight: The weight of the barrel is determined using the following formulae.

Wbl = .02Lb

Wbh = .03Lb

Wbl: Weight (in kilograms) of a light (shotgun) barrel.

Wbh: Weight (in kilograms) of a heavy barrel.

Lb: Length (in centimeters) of the barrel.

Barrel Price: The price of the barrel is determined using the following formula:

Cr = WbBtm

Cr: Price of the barrel in credits.

Wb: Weight of the barrel in kilograms.

Btm: Barrel type multiplier, as determined by the following table:

Type	*Btm*
Smoothbore	100
Rifled	200

Note: Owners of **Fire Fusion and Steel** will notice that black powder rifles have a barrel that weighs as much as a heavy rifled barrel but costs only as much as a light rifled barrel. This is a new type of barrel called Black Powder Rifled.

Actual Muzzle Energy: Once the barrel length is decided on, the weapon's actual muzzle energy can be determined using the following formula.

E = Ea{1 + (0.5[Blp-1])}

E: Actual muzzle energy (in joules) of the weapon.

Ea: Average muzzle energy (in joules) of the ammunition.

Blp: Actual barrel length (cm) dived by average barel length (cm): Bl/Bla

Bl: Actual length (in centimeters) of the barrel of the weapon.

Bla: Average barrel length (in centimeters) for the ammunition used.

If a multiple bullet (i.e., shot) round is fired from the weapon, divide the actual muzzle energy of the round by the number of bullets in the round to determine the energy of each bullet. This is the value used when calculating damage, penetration, and range for multiple round bullets.

Damage: Once muzzle energy is known, it is possible to calculate damage using the following formula.

D = (√E)+15

D: damage value (if D = less than 0.8, damage is 1D6–1, written as "–1.").

E: muzzle energy (in joules).

With a multiple bullet round damage is calculated separately for each bullet. The result is the medium range damage of each bullet. The close range damage *of the entire round* is determined by the following formula:

Dr = .75NDb

Dr: Damage value of the round.

Db: Damage value of a single bullet.

N: number of bullets in the round.

Penetration Rating: It is also possible to determine penetration rating of rifle bullets once muzzle energy is known by consulting the following table.

E	*Pen*
0-2000	Nil
2001-3000	1-Nil
3001-5000	2-Nil
5001-10,000	2-3-Nil
7001-20,000	2-4-6
20001-50,000	2-3-4
50,001+	2-2-3

(*Note*: If using **Fire, Fusion and Steel,** use the penetration table published there but treat all black powder weapons as being one energy category lower, i.e., a black powder weapon of 601-2000 Mj uses the penetration rating for the 0-600 line.)

Smoothbores (shotguns and muskets) are treated diferently, as their bullets tend to be heavy and slow-moving. All smoothbore bullets (both spherical ball and shot) have a penetration of 3-4-5.

(Note that the very high close-range damage of multiple-bullet shotgun shells is caused by multiple bullet hits, each with a lower damage value. In most cases the penetration of multiple bullets from a shotgun will be nil.)

2. LOCK

The lock is the mechanical heart of a black powder firearm. It allows the user to fire the weapon by means of a trigger which activates the mechanism of the lock and in turn ignites the propellant powder charge. Different varieties of locks are available at different tech levels. All locks have a length of 0 (they add nothing to the length of the weapon as they are mounted alongside the barrel) and have a fixed weight, price, and reload time (given in number of actions), as shown on the following chart.

TL	*Type*	*Mass*	*Price*	*Reload*
2	Match Lock	0.3	30	4
2	Wheel Lock	0.6	100	3
2	Snaphanse	0.5	200	2
2M	Flint Lock	0.5	50	2
3M	Percussion	0.3	20	2

3. STOCKS

Stocks refer to rifle stocks and pistol grips. The desired stock for the weapon is selected from the following table. Note that carbine stocks are generally fitted to rifles with short barrels (up to 80% of the average barrel length for the cartridge) or sport versions of rifles. They are not considered sturdy enough for full-length rifles in military use. At tech level 2, "carbines" are often called arquebuses or musketoons.

TL	*Type*	*L (cm)*	*M (kg)*	*Cr*
2	pistol grip	0	0.4	10
2	wooden stock	35	2.5	30
2	carbine stock	25	1.5	25
3	pistol grip	0	0.3	10
3	wooden stock	25	1.5	25
3	carbine stock	25	1.0	20

Range: Once the type of stock is known, the weapon's range can be calculated according to the following formula:

SR = (√E) CmBlm

SR: Short range (in meters) of a weapon.

E: Muzzle energy (in joules).

Cm: Configuration modifier, as shown below. If two configuration descriptionss apply to the same weapon, multiply them together to determine the total configuation multiplier.

Configuration	*Cm*
One-handed	0.4
Two-handed*	1.3
Smoothbore single shot**	0.5

*Note: Two-handed refers to weapons specifically designed to be fired with two hands, and thus including a stock instead of simply a pistol grip.

**Note: Shotgun single-slug rounds, but *not* multiple-shot rounds

Blm: Modification to short range for barrel length. The barrel length modifier is determined by the following formula:

Blm = 1 + ([Blp–1] ×C)

Blm: Barrel Length Modifier.

Blp: Actual barrel length (cm) dived by average barel length (cm): Bl/Bla

Bl: Actual length (in centimeters) of the barrel of the weapon.

Bla: Average barrel length (in centimeters) for the ammunition used.

C: Constant. If (Blp–1 is a negative number, the constant is 1.2. If (Blp–1 is a positive number, the constant is 0.75.

Recoil: Now the weapon's recoil when firing a single shot can be calculated.

R = [(0.15 $\sqrt{E}$)+Ww] + Em

R: Recoil number

E: Muzzle Energy

Ww: Weight, in kilograms, of weapon (loaded)

Em: Modifier for high muzzle energy. If the weapon has high muzzle energy, add to the final recoil as shown on the chart below.

E	*EM*	*E*	*EM*
1001+	1	10,001+	4
2501+	2	20,001+	5
5001+	3	50,001+	6

Bulk: Once the final length of the weapon has been determined the bulk can be calculated. Bulk is equal to the weapon length (in centimeters) divided by 15, rounding all fractions down.

4. ADDITIONAL CONSIDERATIONS

The following items are either options that can be added to a weapon, or are special circumstances that must be considered.

Bayonet Lugs: Bayonet lugs are simple standardized brackets at the end of the weapon barrel. A bayonet lug costs nothing, has negligible mass, and adds no length to the weapon, but must be specified as part of the design.

A bayonet is less useful than a hand-held knife unless it is mounted on a well-balanced weapon with sufficient length to allow it to be used as a spear point. This is affected by tech level and bulk.

Tech Level: Weapons with fixed bayonets at tech level 2 suffer a +1 Diff Mod for their chances to hit in melee combat, due to the bulky and heavy nature of stocks.

Bulk: Only weapons with a bulk of 4 or more may profitably benefit from a bayonet lug. Shorter weapons may have them, but the mounted bayonet counts as a short range (instead of long range) melee wepon and suffers a +1 Diff Mod for its chance to hit in melee combat. Note that this translates into a +2 Diff Mod if the weapon uses a tech level 2 stock.

Reload Time: The listed reload number is that used by the weapon. However, the reload time may be increased due to extreme bulk, type of ammunition used, and presence of a fixed bayonet.

Extreme Bulk: Very long weapon are difficult for a single soldier to load by means of conventional muzzle loading techniques. Add one to the reload value per bulk number in excess of 9. For example, a flintlock musket with a bulk of 11 would have a reload rating of 4, meaning that it requires four actions to reload.

Ammunition Type: Patched ball and loose powder ammunition talke longer to reload than conventional cartridges. These increases are cumulative, and so a flint lock rifle firing a patched ball and using loose powder (instead of a paper cartridge) would have a reload time of 4. These modifiers should be noted with the ammunition, however, instead of the weapon, since the same weapon firing a paper cartridge spherical bullet would have a reload rating of 2.

Ammunition	*Reload*
Patched Ball	+1 action
Loose cartridge	+1 action

Fixed Bayonet: Add one to the reload time of any muzzle-loaded small arm which has its bayonet fixed on its bayonet lug.

Multiple Ammunition Types: Black powder rifles must fire either a conical bullet or a patched spherical bulet to take advantage of the weapon's rifling. A rifle can fire an unpatched spherical ball, but performs like a musket when it does so. When evaluating a black powder rifle, it is a good idea to also evaluate its performance with unpatched ball ammunition. Most of the differences between a rifle and a smoothbore are included in the performance of the ammunition itself, but when calculating range be sure to include the 0.5 smoothbore multipler.

WAGONS

Wagons may be designed for use on low-tech worlds using the Ground Vehicle Design sequence in **FF&S** with the following additions and exceptions:

Chassis: The chassis is generlaly made of wood, and need only have an equivalent armor value of 0.2. Use the following values for wood construction:

TL	Type	Toughness	Mass	Price (MCr)
1	Wood	0.2	0.8	0.001

Since the wagon is drawn by draft animals, no internal provision need be made for a power plant.

Suspension: Add this line to the Suspension table

Type	*TL*	*Vol.*	*Mass*	*SA*	*Price*
Wagon Wheel	1	3.5	0.1	70	.002

Power Plant: Wagons are pulled by draft animals which become the wagon's power plant. Each draft animal pulls with a force in megawatts equal to its mass in tonnes multiplied by 0.0005. A 2-tonne draft animal, for example, pulls with the equivalent of 0.001 MW.

Horses average 350 kg in mass.

Oxen average 600 kg in mass.

Crew: One wagon driver on a bench seat, which counts as a restricted passenger seat.

Passengers: If desired, additional bench seats may be installed for passengers. Treat these as Restricted Seats.

Road Speed:

Base road speed in kilometers per hour = (MW + LM) x 7000.

MW = pulling power, in megawatts, of the draft animals.

LM = loaded mass in tonnes of the vehicle, excluding the mass of the draft animals.

However, road speed is limited to the maximum speed of the draft animal pulling the vehicle. Light draft animals (massing 500 kilograms or less) have a maximum road speed of 5 kilometers per hour. Heavy draft animals (massing over 500 kilograms) have a maximum road speed of 2.5 kilometers per hour.

Cross-Country Speed: Base cross-country speed in kilometers per hour = (MW + LM)x4000.

However, cross-country speed is limited to the maximum speed of the vehicle being drawn and the maximum speed of the draft animal drawing it (as noted above). Vehicle maximum cross-country speeds are limited by the loaded mass (in tonnes, but not counting the mass of the draft animals) of the vehicle, as shown in the box to the right.

LM	*Max Speed*
0.4	4.5
0.6	4.0
0.8	3.5
1	3.0
>1	2.5

Combat Move: The combat movement of animal-drawn vehicles (in meters per turn) is the vehicle's maximum speed (in kilometers per hour) multiplied by 2.15, rounding the result to the nearest increment of 5.

BOW WEAPON DESIGN

Bow weapons are projectile weapons that use mechanical energy (rather than chemical energy as in firearms) to launch projectiles intended to do damage to a target. As such, they are low-tech alternatives or precursors to firearms, but also remain in limited use at high tech levels in specialized roles or for sporting and recreational purposes.

1. Design

A bow is defined by three characteristics: material, length, and type. As some of these are tech-level dependent, the designer must first determine the tech level of design and then specify its exact characteristics.

Material: There are five materials from which bows are commonly made, as shown on the Bow Material Table below. Select one for the bow.

Length: Bow length is measure in meters from tip to tip. Select any length desired.

Mass: Based on the length and material, calculate the mass of the bow. The mass in kilograms per meter of bow length is given on the Bow Material table. Multiply this value by the bow length in meters to determine its total mass in kilograms.

Shaft Energy: Based on the length and material, calculate the energy of an arrow fired from the bow (called its shaft energy). The shaft energy, in joules per meter of bow length, is given on the Bow Material table. Multiply this value by the bow length in meters to determine its total shaft energy in joules.

Price: Based on the length and material, calculate the price of the bow. The price in credits per meter of bow length is given on the Bow Material table. Multiply this value by the bow length in meters to determine its total price in credits.

Type: There are two types of bows: conventional bows and crossbows. If a conventional bow, the design process is complete.

Any bow at tech level 1 and higher may be a crossbow, and any bow longer than the average height of an adult of the race for which it is designed *must* be a crossbow. (Humans have an average height of 1.8 meters.) Crossbows are not available at tech level 0.

Crossbows require a stock/trigger and a cocking mechanism in addition to the bow itself. A bow with a shaft energy of 500 or more joules requires a windlass, and is called a heavy crossbow. A bow with a shaft energy of less than 500 joules requires only a cocking handle and is called a light crossbow.

Consult the Crossbow Hardware Table for the masses and prices of these items and add them to the mass and price of the bow to determine the total mass and price of the weapon.

BOW MATERIAL

TL	*Material*	*M*	*E*	*Cr*
0	Wood	0.6	50	100
1	Horn	0.5	60	150
1	Composite	0.7	70	200
2	Steel	2	150	200
7	Composite Steel	1	200	300

TL: Tech level of construction.
Material: material used to construct the bow.
M: Mass, in kilograms, per meter of bow length.
E: Shaft energy, in joules, per meter of bow length.
Cr: Price in credits per meter of bow length.

CROSSBOW HARDWARE

Item	*Mass*	*Cr*
Stock/trigger	1.5	50
Cocking handle	0.5	25
Windlass	1	75

Mass: mass in kilograms of noted item.
Cr: price in credits of noted item.

2. Evaluation

Once the bow is designed, the following combat characteristics can be determined.

Reload Rate: Reload rate, in the required number of actions to prepare another arrow for firing (exclusive of the aiming action) is depenent on the type of bow, as shown below.

Weapon	*Reload*
Bow	1
Crossbow	3
Heavy Crossbow	5

Damage Value: The damage value of an arrow is calculated the same as for a bullet. Divide the square root of its shaft energy by 15 and round to the nearest whole number.

$$D = (\sqrt{E})+15$$

Calculated damage value of less than 0.8, however, become recorded damage values of "–1" (meaning 1D6–1).

Penetration: Any bow with a shaft energy of 601 joules or more has a penetration of 1-Nil. All other bows have a pentration of Nil.

Bulk: The bulk of the bow is the length of the bow in meters divided by 0.15, rounding fractions down.

Required Strength: Required strength is equal to the shaft energy of the bow divided by the torsion efficiency of the bow, rounding fractions to the nearest whole number. Torsion efficiencies are listed below.

Type	*TE*
Conventional Bow	15
Composite Steel Bow	30
Light Crossbow	30
Heavy Crossbow	60

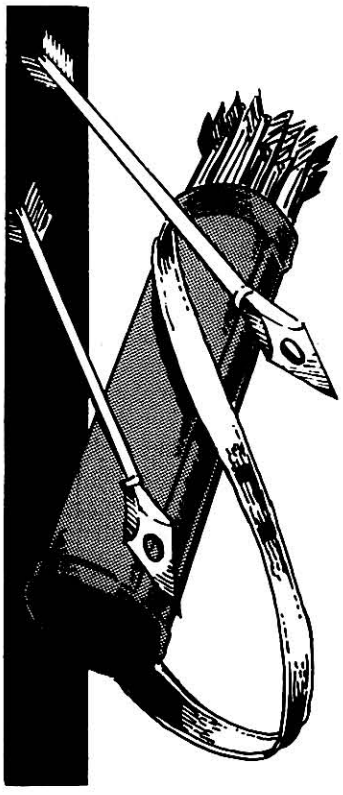
Required strength is recorded in the single shot recoil column of the weapon's record form, and is used in exactly the same manner as a recoil number.

Range: The short range in meters of a bow weapon is equal to three times the square root of its shaft energy in joules, rounding to the nearest increment of 10 meters.

$$SR = 3\sqrt{E}$$

3. Ammunition

Ammunition for conventional bows is called arrows; ammunition for crossbows is called bolts or quarrels. In either case, the specifics are the same.



Price: One arrow or bolt/quarrel costs Cr1.

Mass: One arrow or bolt/quarrel masses 40 grams (0.04 kg).

Ammunition is carried in containers called quivers. Quivers may be worn over the shoulder or hanging from the belt. Quivers are designed by specifying the number of arrows/bolts/quarrels they are to carry.

Price: A quiver costs 0.5 credits per arrow/bolt/quarrel that can be carried in it.

Mass: The mass of a quiver is equal to the mass of the ammunition that can be carried in it.

BLACK POWDER CANNON DESIGN SEQUENCE

For owners of **Fire, Fusion, & Steel** this design sequence will be quite familiar, as it is an abbreviated version of the CPR gun design procedure. This sequence covers black powder artillery built at tech levels 2 and 3. A black powder cannon is a specialized (primitive) form of CPR gun relying on a less efficient form of propellant.

Part I: Weapon Design

A. Specifications

The characteristics of black powder cannon are determined by five specifications. In addition, the weapon's muzzle energy is used through the rest of the design sequence and is calculated at this time.

1. Tech Level: Select a tech level appropriate to the world where the gun was built. These weapons are built at tech levels 2 and 3. Some weapon features are described as "mature" tech level 3 innovations, and so are only available at mature tech level 3 worlds (abbreviated tech level 3M). See page 92 for a discussion of mature tech levels.

2. Type: There are five types of black powder cannons: mortars, howitzers, smoothbore guns, rifled muzzle-loading guns, and rifled breach-loading guns. Mortars and smoothbore guns are available at tech level 2 and up. Howitzers are available at tech level 3 and up. Rifled guns (both types) are available at tech level 3M.

3. Bore Size: Bore size, also known as caliber, is the diameter of the gun's bore. The smallest black powder cannon has a bore of 5cm. The cannon table lists bore sizes in increments of centimeters, but intermediate sizes may be selected as well, such as 7.62cm.

4. Barrel Length: Barrel length is expressed as a length in calibers. That is, a 12cm gun with a barrel fifteen calibers long would be (12x15=180) 180 centimeters long. Barrels may be of any length desired up to 80 calibers. Howitzers may not be any more than 12 calibers long while mortars may not be any more than 5 calibers long. Field guns usually range from 15-25 calibers long while longer barrels are usually reserved for heavy siege artillery.

5. Mount: Mortars must be mounted on a mortar carriage, which is a flat stable platform designed to take the stress of high angle fire. Guns and howitzers may be mounted either on field carriages or truck carriages. Field carriages have a single axle and two large wheels, with a trail that rests on the ground during firing. It is designed to provide both a mobile carriage and a stable firing platform. Truck carriages are lower and generally have two axles and four small wheels. They are lighter and handier, but are not suitable for cross-country movement. They are mostly used in fortresses and aboard ships.

6. Muzzle Energy: The cannon table (page 99) lists the muzzle energy, in megajoules (Mj), of each bore size gun assuming a barrel length of 60 calibers. (Note that the information on this table is the same as that printed on page 109 of **Fire, Fusion, & Steel.**) For bore sizes which fall between those listed on the table, use interpolation to find the correct muzzle energy.

For every caliber in length longer than 60, increase the muzzle energy by 1%.

For every caliber less than 60, reduce the muzzle energy by 2%, until the weapon reaches 15 calibers. For every caliber in length less than 15 calibers, reduce the muzzle energy by 1%.

When this calculation is completed, multiply the result by the configuration modifier found on the Cannon Configuration table to the right.

CANNON CONFIGURATION

Configuration	*Multiplier*
Smoothbore Gun	0.3
Rifled Gun	0.6
Howitzer	0.25
Mortar	0.15

B. Mass

The complete cannon weight is equal to the weight of the cannon barrel plus the carriage.

1. Gun Mass: Consult the Cannon table (page 99) and read the weapon mass (in tonnes). The mass on the table assumes a 60-caliber gun. Increase or decrease the mass by 1% for each caliber change in length up or down. A gun 25 calibers long, for example, is 35 calibers less than 60, and so would mass (100–35=65) 65% of the mass shown on the table.

If the bore size falls between two bore sizes on the table, interpolate the correct value.

Once this calculation is done, multiply the result by the configuration multiplier found on the table below.

Configuration	*Multiplier*
Mortar	1.5
TL 2 gun	1.0
TL 3 Gun	0.75
Howitzer	0.6

2. Carriage Mass: The carriage mass of a cannon, in tonnes, is determined by its barrel mass, configuration, and tech level, according to the following formula:

CrM = TM × CM × BM

CrM: Carriage mass in tonnes.
BM: barrel mass in tonnes.
CM: configuration modifier from table below.
TM: tech multiplier from table below.

CONFIGURATION MODIFIER

Configuration	*CM*
Gun, truck carriage	0.6
Gun, field carriage	1
Howitzer, truck carriage	0.9
Howitzer, field carriage	1.5
Mortar	0.8

TECH MULTIPLIER

TL	*TM*
2	2
3	1

C. Gun Crew

The number of crewmen required to man a gun depends on its bore size and carriage. A field gun or howitzer requires crewmen equal to its bore size in centimeters (rounding fractions down) plus 5. A mortar or a cannon on a truck carriage requires crewmen equal to its bore size in centimeters (rounding fractions down).

A 7.6cm field gun, for example, requires a crew of 12, while the same weapon on a truck carriage requires only 7 crewmen.

D. Range

Cannons have four direct fire ranges: short, medium, long, and extreme. Black powder weapons cannot engage in indirect fire in the modern sense, although mortars and howitzers can lob shells over obstructions.

Short range is mostly a function of the muzzle velocity of a weapon, which is largely determined by its barrel length. A secondary consideration is the size of the round, as larger rounds lose velocity from drag more slowly than do smaller rounds.

Short direct fire range in meters for a black powder cannon is equal to the sum of its bore size in centimeters plus its barrel length in calibers plus 20, all multiplied by a configuration multiplier.

SR = Cm(B+L+20)

Configuration	*Cm*
Howitzer (TL 3 only)	2
TL 2 SB gun	2.5
TL 3 SB gun	3
TL 3M Rifled ML	5
TL 3M Rifle BL	4.5

Mortars calculate range differently. Mortars have only a long range and an extreme range (twice long range). They may not fire at any target at ranges less than their calculated long range nor more than their extreme range, and all shots fired are resolved as extreme range fire.

Long range is calculated using the following formula:

$$LR = B \times BL \times TM$$

LR: long range in meters. Mortars have only a long range and an extreme range. May not fire at anything at less than long or greater than extreme. All shots count as extreme range.

B: bore in cm.

BL: barrel length in calibers.

TM: tech level modifier.

TL	TM
2	5
3	12

E. Reloading

The time the weapon requires to reload is a function of the mass of its barrel and whether it is a breachloader or a muzzleloader.

The number of five-second turns required to load a round in a tech level 2 muzzleloader is equal to the the mass of the barrel in tonnes multiplied by 7, rounding all fractions to the nearest whole number (but rounding any result of less than 1 up to 1).

The number of five-second turns required to load a round in a tech level 3 muzzleloader is equal to the the mass of the barrel in tonnes multiplied by 5, rounding all fractions to the nearest whole number (but rounding any result of less than 1 up to 1).

The number of five-second turns required to load a round in a breachloader is equal to the the mass of the barrel in tonnes multiplied by 4, rounding all fractions to the nearest whole number (but rounding any result of less than 1 up to 1).

The minimum reload time for a muzzle-loading black powder cannon is 3 turns. The minimum reload time for a breach-loading black powder cannon is 2 turns.

F. Price

The price of the weapon is equal to the sum of the price of the barrel and the carriage, both of which are determined by the mass of the component. The price of each component in millions of credits is equal to its mass in tonnes times its cost multiplier, shown in the box above.

Component	Cost Multiplier
Barrel	0.02
Carriage	0.002

G. Set-Up

All towed field cannon must be set up before they can fire. Ship and fortress guns on truck carriages are assumed to be set up and ready to fire (once they have been loaded).

The time, in five-second combat turns, needed to set up a towed cannon on a field carriage is equal to its bore size in centimeters times 4.

The time, in five-second combat turns, needed to set up a mortar is equal to its bore size in centimeters times 8.

H. Volume

The volume of a cannon in cubic meters, for purposes of transportation or mounting in a fortress or ship, is equal to its mass in tonnes.

Part II: AMMUNITION

A complete round of ammunition for a cannon consists of a projectile and a propelling charge of black powder. At tech level 2 the propelling charge is usually poured into the cannon from a barrel or put in with scoops. Superior textile manufacturing techniques at tech level 3 allow widespread and inexpensive use of linen powder charges, making loading quicker.

A. Specify Projectile Type

There are four different projectile types available for black powder cannon, each with its own special function.

1. Shell: This is a hollow projectile filled with black powder and detonated by a burning fuse. The time to bursting is controlled by cutting the fuse to different lengths. Smoothbore weapons (including black powder mortars and howitzers) fire spherical shell, so-called due to the shape of the projectile, while rifled weapons fire conical shell with a larger bursting charge.

2. Shot: This is the most common projectile fired by early black powder cannons, consisting of a solid iron shot. Smoothbore guns fire spherical shot while rifled guns fire conical shot.

3. Cannister: Canister is a tin cylinder filled with musket balls. When fired, the tin cannister bursts upon leaving the gun and scatters the musket balls, much like a large shotgun.

4. Shrapnel: This round, available only at tech level 3M, is a combination of shell and cannister, the hollow projectile filled with both powder and ball and with a time fuse. Shrapnel is actually available at tech level 3, but the unreliability of the fuses makes it little different than common shell in effect and so it is ignored until tech level 3M.

B. Tech Level

The principal effect of tech level is to limit the availability of certain projectile types, as shown at right.

TL	Projectile
2	spherical shot and shell, cannister
3M	conical shot and shell, shrapnel

C. Projectile Diameter

The projectile diameter is the bore of the gun (in centimeters) from which the round is fired.

D. Damage Value

Damage value is a measure of the force generated at the point of impact by the projectile. In the case of shell, this is a measure of the explosive force of the round, and is called concussion. Non-exploding rounds do damage by the energy of impact. Damage is calculated differently for various types of projectiles.

1. Shell: Shells do damage by the concussion of the explosion of their bursting charges. The concussion value of the charge is calculated using the following formula:

$$C = Tm \times D^2$$

C: Concussion value.

D: Projectile diameter in centimeters.

Tm: Tech level modifier, as shown on the chart to the right:

TL	Tm
2	0.02
3	0.03
3M*	0.05

* Used only for conical shell

2. Shot: Shot projectiles have a damage value equal to their diameter in centimeters multiplied by 2.2. This is a constant value for use only for direct hits on personnel. It is never used versus vehicles or structures (for which purpose the penetration value, calculated below, is used).

3. Cannister: Each ball from a cannister round does personnel damage equal to fragments by burst area (2D6 within the primary radius, 1D6 in secondary).

4. Shrapnel: Each ball from a shrapnel round does personnel damage equal to fragments by burst area (2D6 within the primary radius, 1D6 in secondary).

E. Burst

Burst radius defines the area covered by the primary effects of a bursting warhead, usually the area covered by potentially lethal fragments or musket balls.

The formulas below give exact burst radii. To convert to the standard **Traveller** burst area figures resolved to the 10-meter grid,

round to the nearest 10-meter increment (as listed on page 284 of the basic rules). For example, 7 meters rounds to 5, 12 rounds to 15, 30 to 35, etc.

1. Shell: The burst radius of a shell is the primary burst area covered by fragments. The burst radius in meters is the square root of the warhead's concussion value multiplied by 7 for guns and howitzers and by 10 for mortars.

2. Shot: Shot does not explode and so has no burst radius.

3. Cannister: Unlike shell, cannister rounds have an elongated burst area, since the musket balls keep moving along the ballistic path of the cannister after it disintegrates.

The primary burst area is the area immediately beyond the muzzle of the firing cannon, while the secondary burst area is the area after that. The primary burst area is defined as half of the short range of the cannon.

4. Shrapnel: The burst radius of a shrapnel round is the primary burst area covered by fragments. The burst radius in meters is the square root of the warhead's concussion value multiplied by 15.

F. Penetration

Cannon are usually used against vehicles or structures, and so their penetration is expressed as a penetration value, the total penetrative capability of the round.

1. Shell: Penetration of a shell is a function of bore size. Subtract 7 from the bore size (in centimeters) to determine the penetration value of the shell. All shell rounds have a constant penetration value and so the letter "C" is written after the value. Rounds with a penetration value of less than 0 are shown as "Nil." Rounds with a penetration value of 0 have that listed as their penetration value (meaning that the final penetration is the base 2D6 roll without any addition).

2. Shot: Shot relies on muzzle energy to pierce hostile armor. Penetration value is a function of range and muzzle energy. The base penetration of solid shot ammunition at medium range is based solely on muzzle energy (in megajoules) of the gun, as shown below.

If Mj = 12+, then PV = Mjx4.
If Mj < 12, then PV = Mjx5 (but never higher than 48).
If Mj < 9, then PV = Mjx6 (but never higher than 45).
If Mj < 7, then PV = Mjx7 (but never higher than 43).
If Mj < 5, then PV = Mjx8 (but never higher than 35).
If Mj < 1.5, then PV = Mjx10 (but never higher than 12).
If Mj < 1, then PV = Mjx12 (but never higher than 10).
If Mj < 0.5, then PV = Mjx16 (but never higher than 6).
If Mj < 0.3, then PV = Mjx22 (but never higher than 5).

For example, a gun has a muzzle energy of 4.6 Mj. Since this is less than 5 but not less than 1.5 Mj, the gun has a penetration value equal to Mjx8, or 36.8, rounded up to 37, but then reduced to 35 (the maximum PV for weapons with a muzzle energy of less than 5 Mj.

The result of the calculations above is the penetration of conical shot. For spherical shot, multiply the result by 0.7.

Once the medium range penetration value is known, penetration values for the other range bands can be calculated.

At short range, add 15% of the penetration value or a flat value of 10, whichever is less.

At long range, subtract 15% of the penetration value, or a flat value of 10, whichever is less.

At extreme range, subtract 45% of the penetration value, or a flat value of 30, whichever is less.

3. Cannister and Shrapnel: The bullets contained in cannister and shrapnel rounds have the same penetration value as normal fragments (1 in the primary radius, Nil in the secondary).

G. Mass

All spherical shot and shell and cannister projectiles have a mass calculated according to the following formula:

$$PM = (\pi r^3)+100$$

PM: projectile mass in kilograms.
π: 3.1416
r: radius of the projectile (half the diameter) in centimeters

All conical shot and shell and shrapnel use the same formula but multiply the result by 2.

H. Volume

The volume of a projectile in cubic meters for purposes of storage is equal to the mass of the projectile in tonnes divided by 5.

I. Price

The price for ammunition in credits is equal to its mass multiplied by its ammunition type modifier, as shown below

Type	*Modifier*
Shell	10
Shot	5
Cannister	10
Shrapnel	20

Part III: POWDER CHARGE

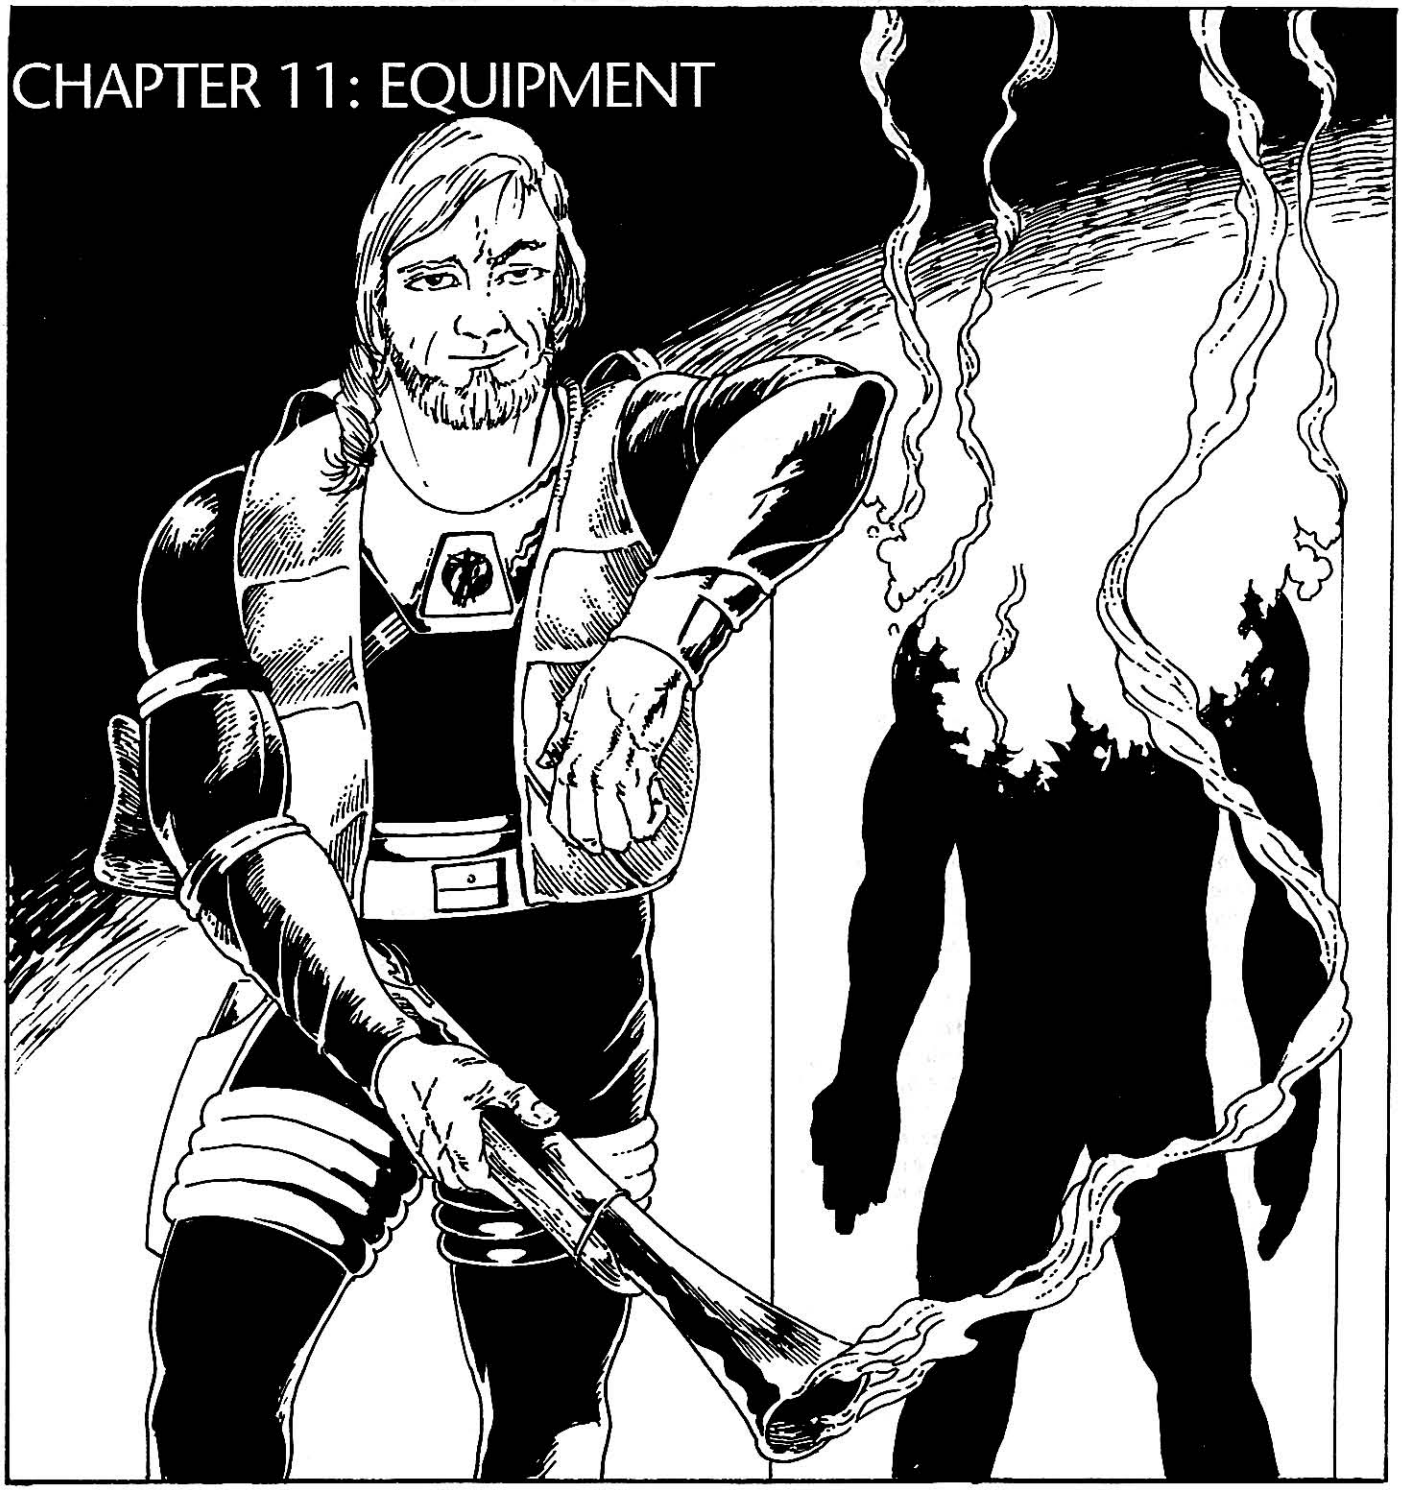
The propelling powder charge (carried in a linen cartridge at tech level 3) is defined in terms of mass and price.

A. Mass

The pass of a powder charge is equal to the mass of the projectile being fired multiplied by 0.25.

B. Volume.

The volume of a powder charge in cubic meters for purposes of storage is equal to the mass of the powder charge in tonnes divided by 5.



C. Price

The price of a powder charge in credits is equal to its mass in kilograms multiplied by 5.

CANNON TABLE

Bore (cm)	*Gun Mass (tonnes)*	*Gun Muzzle Energy (Mj)*
5	0.30	0.8
6	0.42	1.6
7	0.54	2.4
8	0.60	3.6
9	1.0	4.9

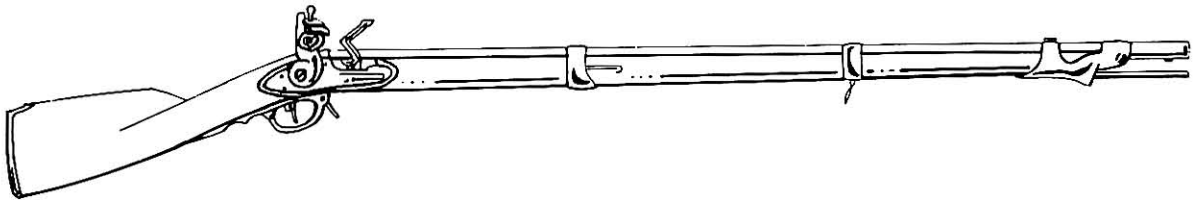
35	40	230
40	50	350
45	60	500

CHAPTER 11: EQUIPMENT

"In comparison to modern firearms, the performance of low-tech black powder weapons such as the blunderbuss is unimpressive, but this is no reason for complacency. At short range, unarmored targets of the blunderbuss will end up just as dead as if they were hit by a plasma pulse."

— Gunnery Sergeant Midushuugi "Leaper" Liebman
RCES Primitive Weapons Familiarization Seminar



Not all of the equipment in the following section is high tech, but it can be dangerous nonetheless. In the Wilds, a long way from hospitals, spare parts bins, and maintenance bays, it only takes one lucky shot to ruin your whole day, and it doesn't matter if that shot is a plasma bolt, an armor-piercing fin-stabilized discarding-sabot bonded superdense kinetic energy penetrator, or a lousy arrow, or even a rock.

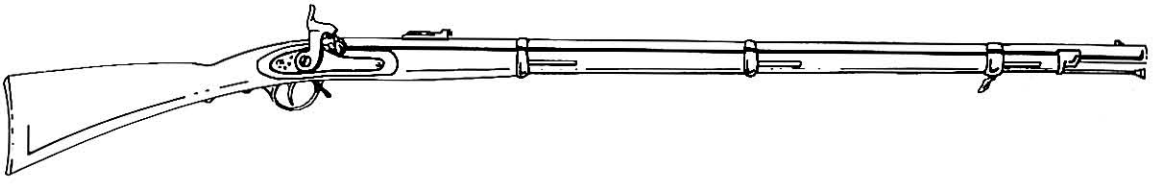
The following pages show the mainstay weapons of worlds of tech levels 2 and 3, from manportable black powder small arms on pages 101-104 up to crew-served cannons on 105-106. These may be encountered carried by "zippers" in the Wilds, or picked up as extemporaneous armament by RC troops, bootstrap team leaders, or undercover agents.

In addition to this low-tech equipment, three new starships suited for colonial transport are presented here, beginning on page 107.

All of the equipment shown here is designed with the **Fire, Fusion, & Steel** Technical Architecture sourcebook, or the design sequence additions found here in this book.

Smoothbore Flintlock Musket
Rifled Musket

Smoothbore Flintlock Musket



A flintlock uses a spring-loaded flint-and-steel striker to ignite the main powder charge in a gun barrel. The weapon illustrated is typical of numerous archaic designs in use on very low TL worlds, and in the hands of poorly equipped militias and insurgents on worlds with higher technology levels. Because of its short range and poor accuracy, smoothbore muskets are most effective when used by massed bodies of soldiers exchanging volley fire.

This weapon holds one individually loaded round inserted in the muzzle, and requires two actions to reload. If prepared paper cartridges are not available, the weapon may be loaded using loose powder and ball, but this takes one additional action.

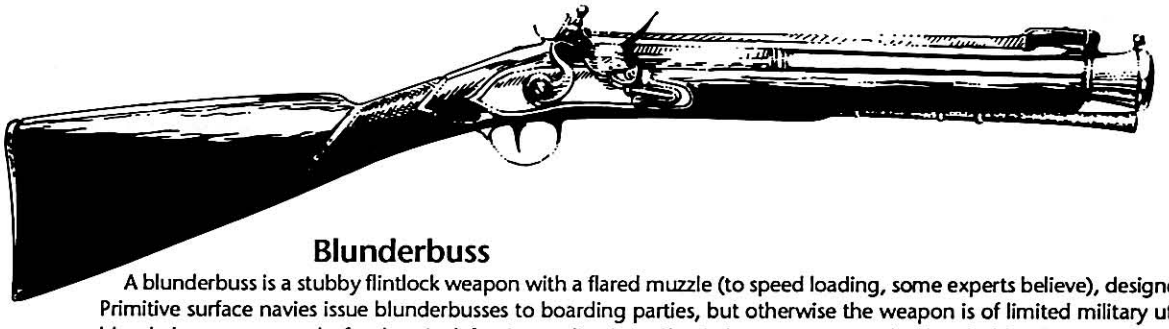
TL: 3
Ammo: 18×52mm black powder and ball in paper cartridge
Muzzle Energy: 1446 joules
Weapon Length: 130 cm
Weapon Weight: 5.19 kg loaded, 5.15 kg empty
Weapon Price: Cr390

Magazine: None.
Ammunition Price: Cr0.4 (Ball)
Ammunition Weight: 40 grams per round
Features: Bayonet lug.

						— Recoil —		
Round	*Reload*	*Dam Val*	*Pen Rtg*	*Bulk*	*Magazine*	*SS*	*Burst*	*Short Range*
18mm P&B	2	3	Nil	8	1i	2	—	30

Rifled Musket

Rifled muskets of the type illustrated are more advanced archaic firearms. Using a rifled barrel and a conical bullet, the rifle musket achieves greater range and damage than the smoothbore version, and the percussion cap ignition system results in fewer misfires. Soldiers using these weapons are able to make use of more modern tactics and need not resort to massed volleys (although the weapons are sometimes used in that fashion).



This weapon holds one individually loaded round inserted in the muzzle, and requires two actions to reload. If prepared paper cartridges are not available, the weapon may be loaded using loose powder and bullet, but this takes one additional action.

TL: 3M
Ammo: 12×76mm black powder and conical bullet in paper cartridge
Muzzle Energy: 2010 joules
Weapon Length: 110.8 cm
Weapon Weight: 4.41 kg loaded, 4.37 empty

Weapon Price: Cr560
Magazine: None.
Ammunition Price: Cr0.43 (Conical bullet)
Ammunition Weight: 43 grams per round
Features: Bayonet lug.

						— Recoil —

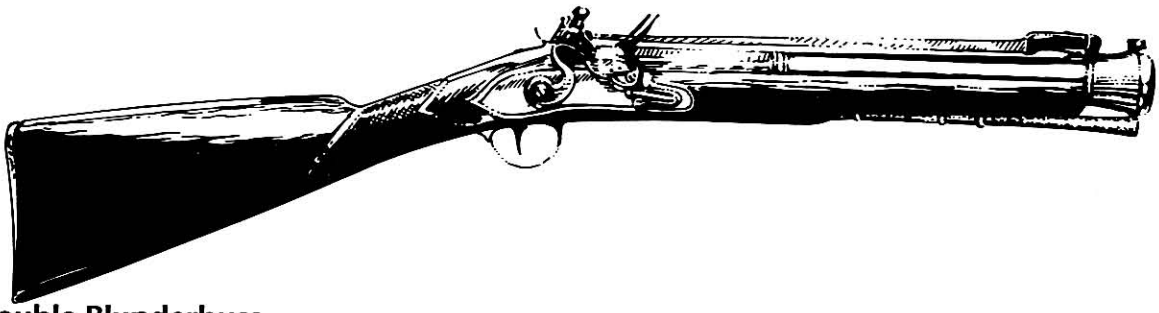
12mm P&B	2	3	1-Nil	7	1i	3	—	80

Blunderbuss
Double Blunderbuss

Blunderbuss

A blunderbuss is a stubby flintlock weapon with a flared muzzle (to speed loading, some experts believe), designed for close-range use. Primitive surface navies issue blunderbusses to boarding parties, but otherwise the weapon is of limited military utility. In civilian hands, blunderbusses are popular for close-in defensive applications. Shot is the most common loading for blunderbusses, because of the devastating short range damage value (rivaling that of many more modern weapons).

The word "blunderbuss" is believed to descend from a word meaning "thunder-gun" an old Terran language known as Dutch. The name is an obvious reference to the weapon's powerful discharge.



The weapon can be fitted with an optional spring bayonet, which adds 0.2 kg to the weight and Cr20 to the price. This bayonet is kept folded against the side or top of the barrel when not in use, and is released by a thumb-operated latch when the firer desires. When released, the bayonet flips forward into position and locks into place, ready for use. The bayonet does not increase the weapon's mass enough to change recoil.

Weapon Price (with Spring Bayonet): Cr185
Magazine: None.
Ammunition Price: Cr0.94 (slug or shot)
Ammunition Weight: 94 grams per round
Features: Optional spring-loaded bayonet.

TL: 2M
Ammo: 20×100 loose black powder and shot or slug
Muzzle Energy: 2021 joules
Weapon Length: 70 cm
Weapon Weight: 2.994 kg loaded, 2.9 empty
Weapon Weight (with Spring Bayonet): 3.194 kg loaded, 3.1 empty
Weapon Price: Cr165

						— *Recoil* —		
Round	*RLD*	*Dam Val*	*Pen Rtg*	*Bulk*	*Magazine*	*SS*	*Burst*	*Short Range*
20mm P & B	3	3	Nil	4	1i	3	—	4
20×100 Shot Short	3	18	Nil	4	1i	3	—	3
Medium	3	1	Nil					

Note: A shot round fired at medium range is resolved as a 5-dice burst.

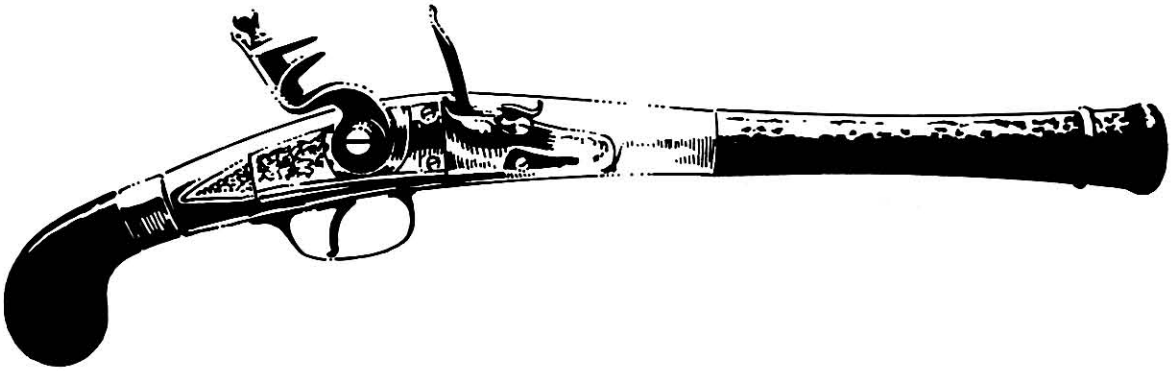
Double Blunderbuss

The double blunderbuss is a standard blunderbuss manufactured with two barrels. As with the normal blunderbuss, shot is the most common load.

This weapon can be fitted with an optional spring bayonet, which adds 0.2 kg to the weight and Cr20 to the price. This bayonet is kept folded against the side or top of the barrel when not in use, and is released by a thumb-operated latch when the firer desires. When released, the bayonet flips forward into position and locks into place, ready for use. With the spring bayonet, the weapon's recoil becomes 2.

The weapon may discharge both barrels in a single 5-second turn, as if the weapon had an ROF rating of SA.

TL: 2M
Ammo: 20×100 loose powder and slug or shot
Muzzle Energy: 2021 joules
Weapon Length: 70 cm
Weapon Weight: 4.394 kg loaded, 4.3 empty
Weapon Weight (with Spring Bayonet): 4.594 kg loaded, 4.5 empty



Weapon Price: Cr305
Weapon Price (with Spring Bayonet): Cr325
Magazine: None.
Ammunition Price: Cr0.94 (slug or shot)
Ammunition Weight: 94 grams per round
Features: Optional spring-loaded bayonet.

						— *Recoil* —

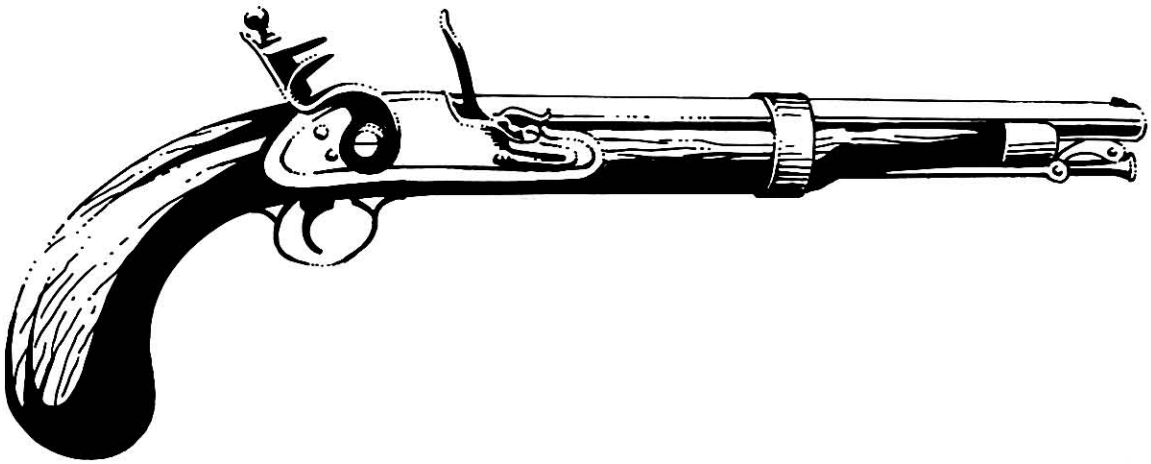
*Reload rate is per barrel.

Note: A shot round fired at medium range is resolved as a 5-dice burst.

Blunderbuss Pistol
Horse Pistol

Blunderbuss Pistol



The blunderbuss pistol incorporates the same bell-mouthed barrel of the standard blunderbuss into a pistol, with a resultant reduction in length and range. As a close-range defensive weapon for cavalry and the like, however, the blunderbuss pistol is very effective.

TL: 2M
Ammo: 20×100 loose powder and slug or shot
Muzzle Energy: 2021 joules
Weapon Length: 45 cm
Weapon Weight: 1.894 kg loaded, 1.8 empty

Weapon Price: Cr150
Magazine: None.
Ammunition Price: Cr0.94 (slug or shot)
Ammunition Weight: 94 grams per round
Features: None.

						— *Recoil* —		
Round	*RLD*	*Dam Val*	*Pen Rtg*	*Bulk*	*Magazine*	*SS*	*Burst*	*Short Range*

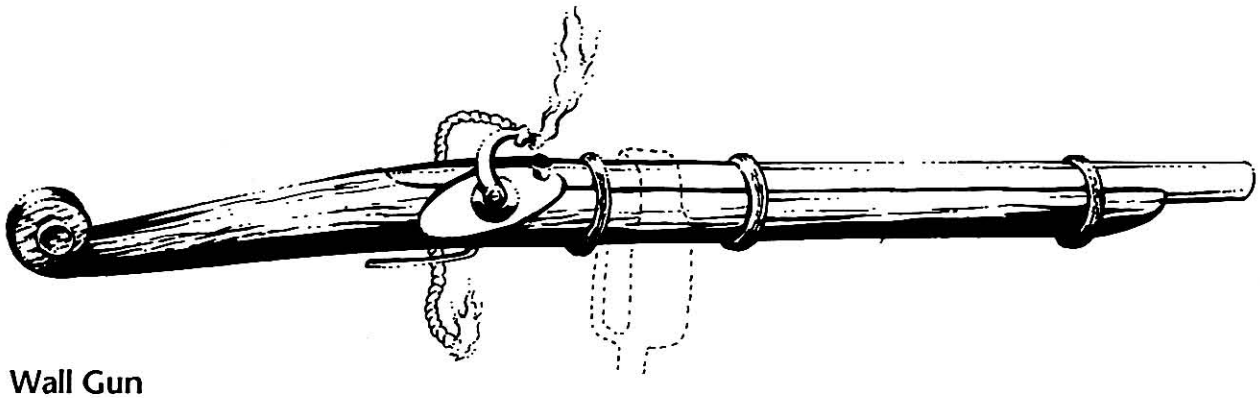
20×100 Shot Short	3	18	Nil	3	1i	5	—	1
Medium	3	1	Nil					

Note: A shot round fired at medium range is resolved as a 5-dice burst.

Horse Pistol



Horse pistols are so-named because they were designed to be used by cavalry mounted on horseback, each soldier carrying two pistols in a pair of holsters attacked to the saddle. These weapons were designed for close-in combat in a swirling cavalry melee, and the range reflects this fact.

TL: 3
Ammo: 15×100mm loose black powder and ball
Muzzle Energy: 1132.09 joules
Weapon Length: 59.9 cm
Weapon Weight: 2.65 kg loaded, 2.6 empty

Weapon Price: Cr239.7
Magazine: None.
Ammunition Price: Cr0.2651 (ball)
Ammunition Weight: 53.0145 grams per round
Features: None.

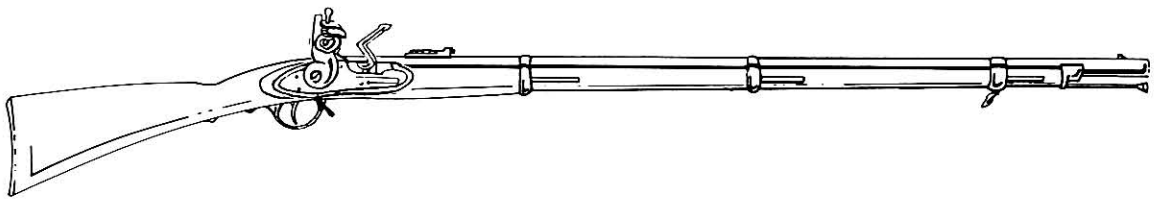
Wall Gun
Flintlock Rifle-Musket

Wall Gun



This monster weapon is too clumsy to be used by individuals in the field, it is normally found on a swivel (pintle mount) on fortifications or boats in order to deter attackers. The long reload time is a distinct disadvantage, but the extremely high short range damage means that the weapon must nevertheless be taken seriously, even by armored opponents.

TL: 2
Ammo: 20×120 loose powder and slug or shot
Muzzle Energy: 3564.9 joules
Weapon Length: 203 cm
Weapon Weight: 6.2731 kg loaded, 6.16 empty

Weapon Price: Cr396
Magazine: None.
Ammunition Price: Cr1.13 (slug or shot)
Ammunition Weight: 113.1 grams per round
Features: None.

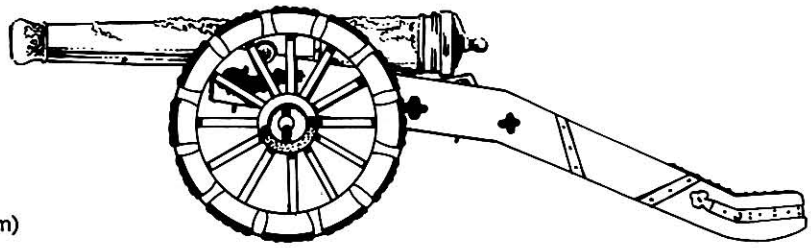
						— Recoil —		
Round	*RLD*	*Dam Val*	*Pen Rtg*	*Bulk*	*Magazine*	*SS*	*Burst*	*Short Range*
20mm P & B	9	4	3-Nil	13	1i	3	—	30
20×120 Shot close	9	72	Nil	13	1i	3	—	14
medium	9	1	Nil					

Note: A shot round fired at medium range is resolved as two 10-dice bursts.
Fired from a wall (pintle) mount, this weapon has negligible recoil and twice the listed range.

Flintlock Rifle-Musket

This weapon is a slightly less advanced version of the percussion rifle-musket described on page 101. It is rifled, fires a conical bullet, and is loaded using a prepared paper cartridge.

TL: 3
Ammo: 12×76mm black powder and conical bullet in paper cartridge
Average Muzzle Energy: 2010 joules
Weapon Length: 110.8 cm



Weapon Weight: 4.61 kg loaded, 4.57 empty
Weapon Price: Cr590
Magazine: None.
Ammunition Price: Cr0.43 (conical bullet)
Ammunition Weight: 43 grams per round
Features: Bayonet lug

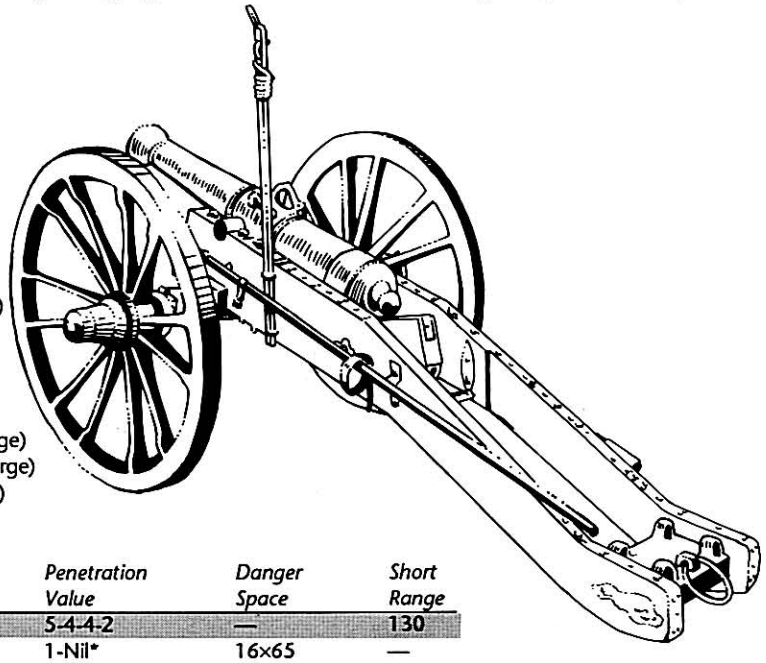
13.5cm Heavy Field Gun
9.5cm Light Field Gun

13.5cm Heavy Field Gun

The weapon described here is one of the heaviest field guns in use at tech level 2, heavier guns being reserved for the siege train. Even so, this was an awkward, if powerful, field piece. Guns similar to this used on Earth during the Renaissance, Thirty Years War, and English Civil War were called "culverins."



TL: 2
Type: Smoothbore gun
Bore Diameter: 13.5 cm
Barrel Length: 24 calibers (324 cm)
Mount: Field Carriage
Muzzle Energy: 1.1214 Megajoules
Weapon Weight: 5.8 tonnes (Barrel: 1.9 tonnes, carriage: 3.9 tonnes)
Weapon Price: Cr46,080 (Barrel: Cr38,400, carriage: Cr7,680)
Crew: 18
Weapon Volume: $5m^3$
Set-Up Time: 13 turns
Ammunition Price: Cr48.5 (shot), Cr97 (Cannister), Cr12 (powder charge)
Ammunition Weight: 9.7 kg (shot), 9.7 kg (Cannister), 2.4 kg (powder charge)
Ammunition Volume: 1.9 liters (projectile), 0.5 liters (powder charge)
Features: None.

*primary radius/secondary radius

9.5cm Light Field Gun

This weapon is representative of the lightest field guns and heaviest regimental guns in use. Similar guns when used on Earth were commonly called six-pounders, after the weight of the roundshot projectile they fired. These light weight guns were the most-often used weapons by horse artillery.

TL: 3
Type: Smoothbore gun
Bore Diameter: 9.5
Barrel Length: 16 calibers (152 cm)
Mount: Field carriage.
Muzzle Energy: 0.1962 Megajoules
Weapon Weight: 1.6 tonnes (Barrel: 0.8 tonnes, carriage: 0.8 tonnes)
Weapon Price: Cr18,150 (Barrel: Cr16,500, carriage: Cr1,650)
Crew: 14
Weapon Volume: $2m^3$
Set-Up Time: 38 turns
Ammunition Price: Cr16.85 (shot), Cr33.7 (Cannister), Cr4 (powder charge)
Ammunition Weight: 3.4 kg (shot), 3.4 kg (Cannister), 0.8 kg (powder charge)
Ammunition Volume: 0.7 liters (projectile), 0.2 liters (powder charge)
Features: None.

7.5cm Rifled Muzzle-Loading Field Gun
12cm Howitzer

7.5cm Rifled Muzzle-Loading Field Gun

This weapon is one of the earliest rifled field guns. Because early muzzle loaders could fire slightly more powerful charges than could breechloaders, muzzle loaders were retained for some time due to their longer range. Guns similar to this one were used throughout the American Civil War, of which the 3-inch Ordnance Rifle, 3-inch Rodman, and 10-pounder Parrot Gun were the most common examples.

TL: 3
Type: Rifled field gun
Bore Diameter: 7.5 cm
Barrel Length: 25 calibers (187.5 cm)
Mount: Field carriage
Muzzle Energy: 0.54 Megajoules
Weapon Weight: 0.6 tonnes (Barrel: 0.3 tonnes, carriage: 0.3 tonnes)
Weapon Price: Cr6,113 (Barrel: Cr5,558, carriage: Cr556)
Crew: 12
Weapon Volume: $1m^3$
Set-Up Time: 30 turns
Ammunition Price: Cr16.5 (conical shot), Cr33 (conical shell), Cr33 (Cannister), Cr66 (Shrapnel), Cr2 (powder charge—cannister), Cr4 (powder charge—all other rounds)
Ammunition Weight: 3.3 kg (conical shot), 3.3 kg (conical shell), 1.7 kg (Cannister), 3.3 kg (Shrapnel), 0.4 kg (powder charge—cannister), 0.8 kg (powder charge—all other rounds)
Ammunition Volume: 0.7 liters (projectile), 0.1 liters (powder charge—cannister), 0.2 liters (powder charge—all other rounds)
Features: None

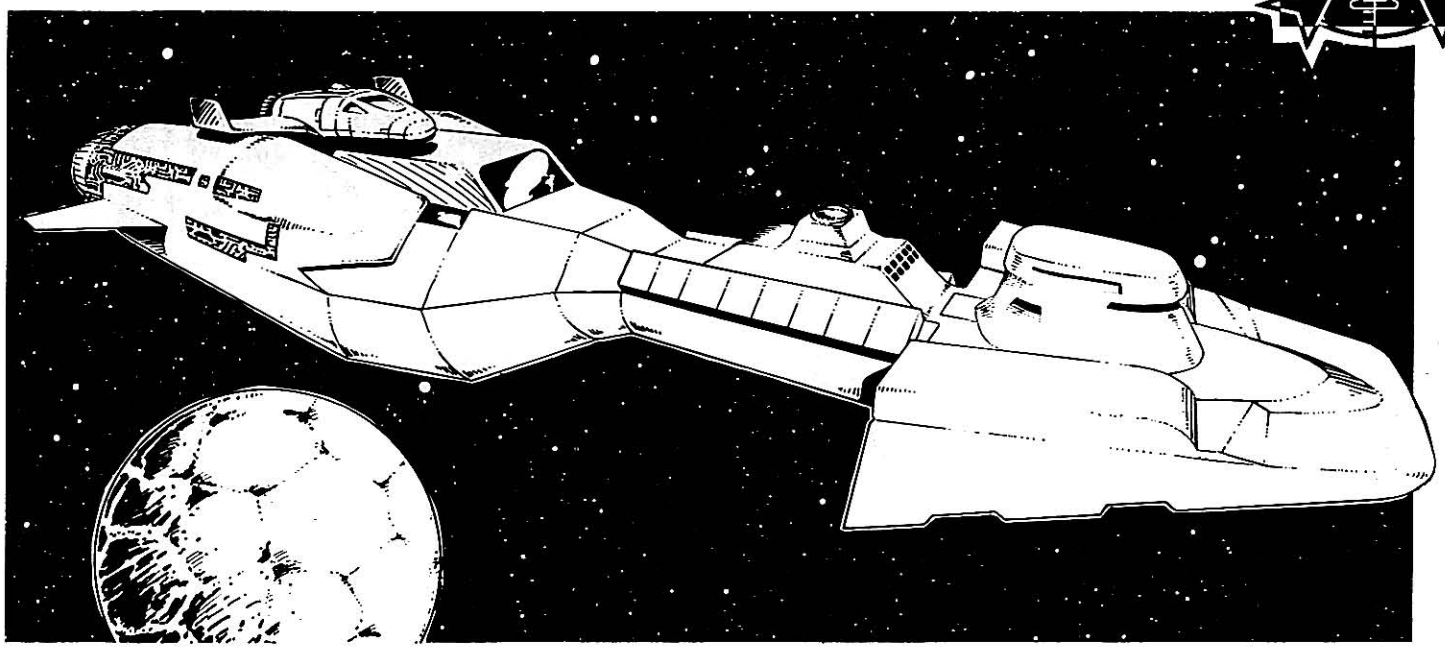
*primary radius/secondary radius

12cm Howitzer

This is a fairly typical howitzer of medium caliber. Weapons similar to this were used during the American Civil War and were called 12-pounder howitzers, so-called for the weight of the solid roundshot which they could (but rarely did) fire.



TL: 3
Type: Howitzer
Bore Diameter: 12cm
Barrel Length: 11 calibers (132 cm)
Mount: Field Carriage
Muzzle Energy: 0.1395 Megajoules
Weapon Weight: 1.6 tonnes (Barrel: 0.6 tonnes, carriage: 1 tonne)
Weapon Price: Cr14,780 (Barrel: Cr12,852, carriage: Cr1,928)
Crew: 17
Weapon Volume: $1.6m^3$
Set-Up Time: 48 turns
Ammunition Price: Cr33.9 (shot), Cr67.9 (Shell), Cr67.9 (Cannister), Cr9 (powder charge)
Ammunition Weight: 6.8 kg (shot, Shell, Cannister), 1.7 kg (powder charge)
Ammunition Volume: 1.4 liters (projectile), 0.3 liters (powder charge)
Features: None.

Tukera Freighter

General Data

Displacement: 2905/3000 tons
Length: 124.29 meters
Price: MCr754.61
Configuration: Needle USL
Hull Armor: 28
Volume: 40,670/42,000 m³
Target Size: M
Tech Level: 14
Mass (Loaded/Empty): 27,364.10/9837.99 tonnes

Engineering Data

Power Plant: 1770 MW Fusion Power Plant (98 MW/hit), 1 year duration (9.802 MW excess power)

Jump Performance: 4 (10,500 m³ fuel for jump 4, 7875 m³ for jump 3, 5250 m³ for jump 2, 2625 m³ for jump 1)

G-Rating: 1G (1500 MW/G), no Contra-Grav

G-Turns: 48 (104 using jump fuel), 187.5 m³ of fuel each

Fuel Tankage: 12,600 m³ (900 tons), plus 177 m³ (12.6 tons) reserved for power plant

Maint: 1055

Electronics

Computer: 2×TL-14 Model St (0.5 MW ea.), 1×TL-14 Model Fb (1 MW)

Commo: 2×1000 AU Radio (only one powered; 10 hexes; 20 MW)

Avionics: TL-10+ Flight Avionics

Sensors: Passive EMS fixed array 150,000km (5 hexes; 0.15 MW), Active EMS 240,000km (8 hexes; 13 MW)

ECM/ECCM: None

Controls: Bridge with 7×Bridge workstations, plus 14 other workstations

Weapons

Offensive: 2×TL-14 150 Mj Laser Turrets (Loc: 10, 11; Arcs: All; 4.2 MW ea.; 1 Crew ea.)

	Short	*Medium*	*Long*	*Extreme*
TL-14 150-Mj Laser Turret	2: 1/10-31	4: 1/10-31	8: 1/10:31	16: 1/10:31

Accommodations

Life Support: Extended (8.134 MW), Gravitic Compensators (5G; 203.35 MW)

Crew: 32 (14×Engineering, 1×Electronics, 2×Maneuver, 2×Gunnery, 4×Maintenance Crew, 3×Flight Crew, 4×Command, 1×Steward, 1×Medical)

Crew Accommodations: 14×Large Staterooms (double occupancy; 0.001 MW ea.), 4×Small Staterooms (single occupancy; 0.0005 MW ea.)

Passenger Accommodations: 8×Large Staterooms (0.001 MW ea), 2×Small Staterooms (0.0005 MW ea), 5×Emergency Low Berths (0.002 MW ea.)

Cargo: 15,208 m³ (1086.3 displacement tons)

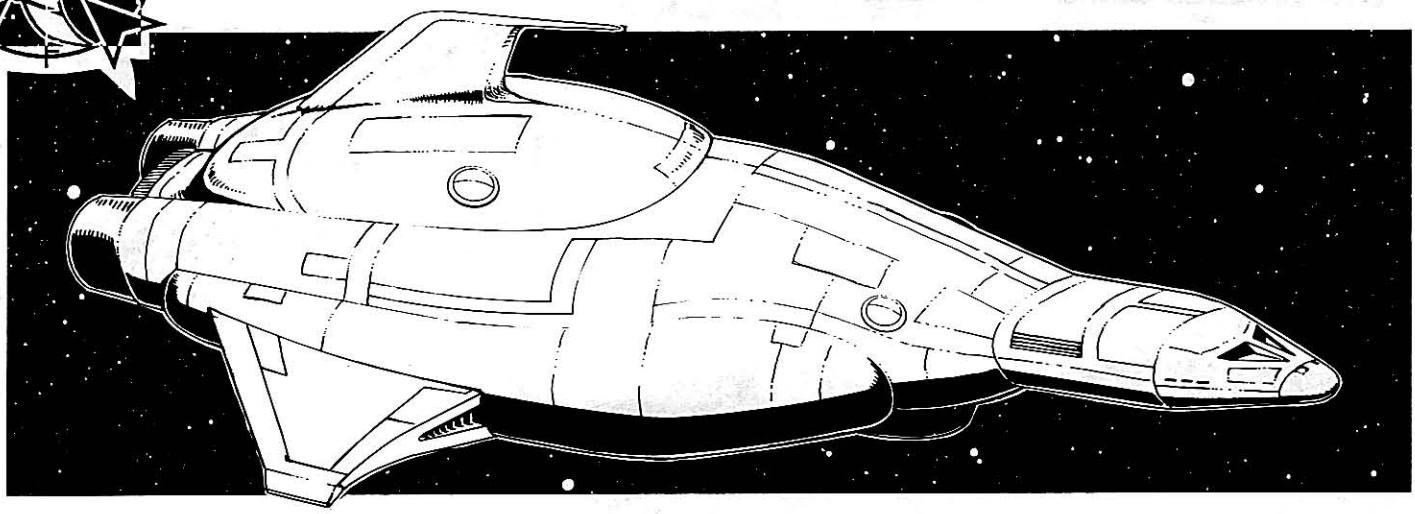
Small Craft and Launch Facilities: 95-ton Shuttle in External Grapple (Unstreamlined)

Air Locks: 29

Notes

The Tukera Freighter is a relic Imperial-era design built for the Tukera Lines, an imperial megacorporation. These freighters were intended for use on civilized trade routes, and were built without a fuel purification plant, as they purchased their fuel at their destinations. For service in the New Era, recovered relic Tukeras are usually fitted with new-build fuel purification plants (1050 m³, 2100 tonnes, 0.42 MCr, and 15.75 MW to purify 10,500 m³ of fuel in 24 hours at TL-12) at the expense of cargo space. This requires the carried shuttle to be used as a fuel skimmer, a time-consuming process as the cutter carries only a maximum 482 m³ of fuel cargo at a time.

They are also built without other features common to ships used in undeveloped areas, such as master fire directors, an extensive defensive armament, and ECM. The ship's excess power allows it to be fitted with additional turret sockets and turrets, but these come at the expense of cargo capacity.



The freighter's drives are scaled to provide full jump and maneuver performance with the 95-ton shuttle attached to the external grapple. However, the shuttle must be powered up to provide its own life support, as the freighter has no excess capacity for this purpose.

On the damage tables below, if the shuttle is not attached, surface shuttle hits are taken by the grapple.

TL-14 150-Mj Laser Turret	2:1/10-31	4:1/10-31	8:1/10:31	16:1/10:31

Accommodations

Life Support: Extended, (14 MW), Gravitic Compensators (5G; 350 MW)

Crew: 47-51 (28×Engineering, 1×Electronics, 2×Maneuver, 2-6×Gunnery, 4×Maintenance Crew, 3×Flight Crew, 7×Command)

Crew Accommodations: 22×Small Staterooms (double occupancy; 0.0005 MW ea.), 7×Small Staterooms (single occupancy; 0.0005 MW ea.)

Passenger Accommodations: None

Cargo: 36,781.25 m³ (2627.23 displacement tons); reduced to 30,131.25 m³ (2152.23 tons) when auxiliary fuel bladder is filled, can be increased to 37,131.25 m³ (2652.23 tons) by removing auxiliary fuel bladder altogether

Small Craft and Launch Facilities: 50-ton modular cutter with fuel module in Internal Hangar (Spacious) with one launch port

Air Locks: 50

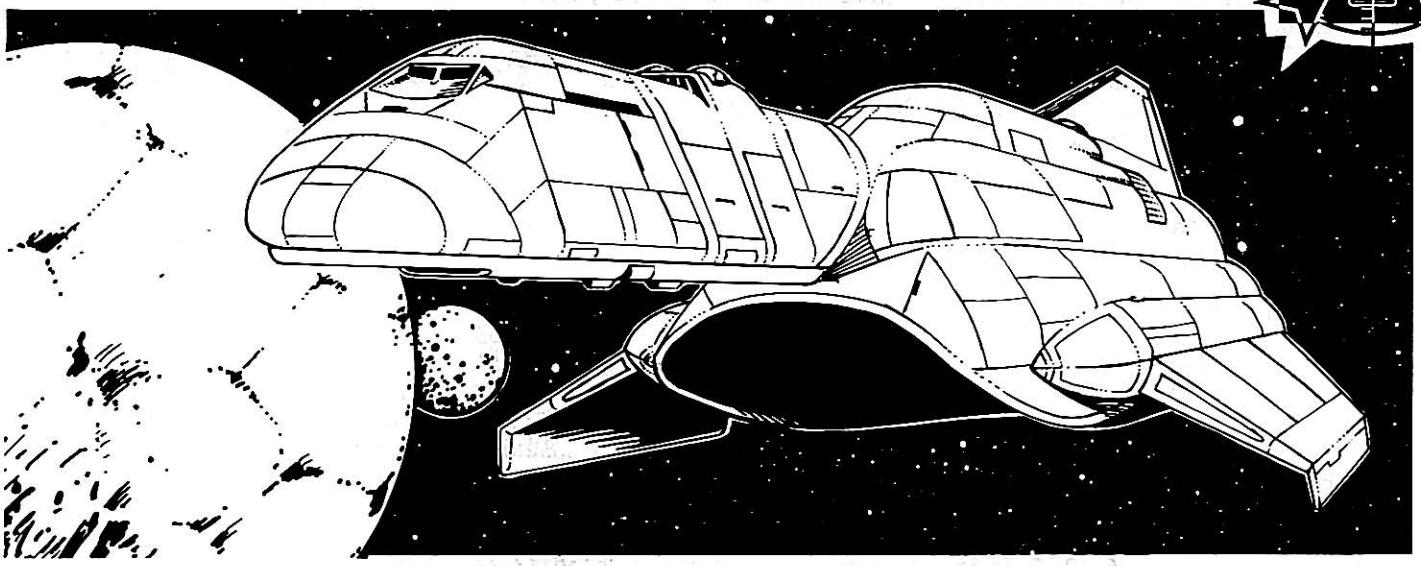
Notes

The *Hercules*-class bulk carrier is the epitome of the lumbering pig of a ship which results from an attempt to maximize cargo capacity within a starfaring hull: fully 52.5% of the ship's displacement is given over to cargo carriage. The *Hercules* was a proprietary design built for Tukera Lines and Akerut Lines (a wholly owned subsidiary of Tukera Lines) during the Last Imperium.

The *Hercules* is a relic pre-Collapse design, optimized for use on the "mains" of the Last Imperium. Mains are astrographic features which are simply a string or clump of star systems grouped so that all of the systems in the group can be reached without having to exceed jump-1. Many ships, notably the standard free traders, remain "trapped" in a single main for all of their service lives, as their jump-1 drives render them incapable of making the 2+ parsec jump to a single world or other main not contiguous with the main they are in. The *Hercules* class is designed to surmount this difficulty with the use of an auxiliary fuel bladder with sufficient capacity to allow two consecutive jump-1s for a total of two parsecs. This allows the *Hercules* to move from one main to another (provided they are not separated by more than a parsec) and enhances its flexibility.

The procedure calls for the *Hercules* to refuel its permanent tanks as well as its collapsible fuel bladder (the bladder displaces 7000 m³ when full and 350 m³ when empty) and make the one parsec jump to deep space (an empty hex on a star map). Here it transfers the fuel from its bladder into its permanent tankage (fuel in a bladder cannot be burned directly, but must be transferred to permanent tankage) for the second jump. Thus the 2-parsec journey takes a nominal two weeks (not counting time to transfer fuel and recalibrate the drives, etc.) rather than the nominal one week of a single 2-parsec jump.

Note that the figures above include a single auxiliary bladder permanently fitted to the vessel. Additional such bladders may be added at a cost of MCr0.7 each. Each bladder displaces 7000 m³ (500 tons) loaded and 350 m³ (25 tons) empty.



Because its two master fire directors can control the ship's four turrets without requiring them to be manned, the *Hercules* crew can be reduced by four members by leaving the turrets unmanned. This naturally prevents the turrets from being fired under local control should the MFDs be taken out of action.

TL-14 fuel purification machinery (8.75 MW) refines 7000 m³ of fuel (full load of jump fuel) in 24 hours. Standard practice is to skim a full load of fuel (jump fuel and reaction mass), refine sufficient fuel to jump, execute the jump, and refine the remainder while in jumpspace. 5% fuel scoops allow the vessel to scoop 14,000 m³ of fuel per hour.

Passenger Accommodations: None

Cargo: 9968.95 m³ (712 displacement tons)

Small Craft and Launch Facilities: 95-ton Shuttle in Internal Hanger (Minimal) with one launch port

Air Locks: 20

Notes

The Frontier Transport in a relic Imperial-era design, and was a multi-purpose cargo vessel used for trade in undeveloped areas. The design was a proprietary design belonging to the Imperiallines shipping line, which primarily served worlds situated off of the main trade routes.

Some ships dispense with some or all of the 10 gunners, as the turrets can be controlled from the two MFDs, which also allows one of the command crew to be dispensed with. This allows the required complement to be reduced to as low as 36, although without crew, the turrets cannot be fired under local control if something happens to the MFDs. The MFDs are also capable of controlling missile turrets, if these are fitted.

TL-14 fuel purification machinery (5.25 MW) refines 4200 m³ of fuel (full load of jump fuel) in 24 hours or 2100 m³ of jump fuel (sufficient for jump-1) in 12 hours. Standard practice is to skim a full load of fuel (jump fuel and reaction mass), refine sufficient fuel to jump, execute the jump, and refine the remainder while in jumpspace. 5% fuel scoops allow the vessel to scoop 5600 m³ of fuel per hour.

An externally identical variant of this vessel was also built for the Last Imperium, but is equipped with jump-6 drives and fuel tankage at the expense of cargo.

To **BUILD** the future

To **DARE** greatly

To take one's **PLACE** in the arena

Life takes place against a grander tableau in the New Era. Without an omnipotent Imperium that has already imposed order on everything, the act of every man, woman, and child looms larger, has a greater impact. And when even seemingly small actions have large results, imagine the sort of effect a person can have when daring greatly. The course of civilizations can be changed.

In the New Era, entire worlds have died, or fallen back into barbarism. These worlds need people to come make them live again, and leaders to take them back into the light. Such people need to have a variety of skills: they must be explorers, they must be builders, they must be leaders. They must have the courage to take on the power of a raw world and emerge victorious. These explorers, these builders, these leaders have a name. They are called World Tamers.

The **World Tamers Handbook** brings to **Traveller®: The New Era** a new arena in which to adventure: the ragged border of civilization, the realm of the unknown on a thousand worlds that do not know the light of civilization. **World Tamers Handbook** provides material to create Survey campaigns in which characters push humanity's knowledge out into the Wilds, Bootstrap campaigns in which characters lift low-tech populations out of barbarism, and Colony campaigns in which characters found and lead expeditions to repopulate entire worlds.

In order to do this, World Tamers Handbook provides rules on colonial economics and infrastructure which allow players and referees alike to understand what makes a colony run, and what decisions need to be made to ensure success. These rules are not only useful for the campaigns in this book, but can be used to flesh out societies in any **Traveller: The New Era** campaign or adventure.

In addition, expanded rules on world generation allows referees to create the details needed by players conducting detailed survey operations in advance of the colony transports.

Finally, additional design sequences expand on the information contained in **Fire, Fusion, & Steel** to allow the design of black powder weapons, bow weapons, and low-technology ground transportation.

A world can be a big, rough, wild place, but no world is too big, too rough, or too wild for characters bold enough to be called world tamers.

WORLD TAMER'S™ HANDBOOK

Worlds to be found
Worlds to be won
Worlds to be tamed

Meet the challenge.

CINETWORK

RCES MIL TRAFFIC, CLASS: **NOTICE TO STARFARERS**, DISTRIBUTION: **MANDTY**, AUTHORITY COMMANDER, RCES DAWN BASE (TRYBEC/0336/AUBAINE, B443610-A), 26/X/1201
KEYWORDS: **VIRUS, HAZARD TO TRAVEL, VAMPIRE**

RC space forces have issued a Notice to Starfarers for the Arvid (0131/Aubaine) and Mitchell (3034/Khulam/Diaspora) star systems. These systems appear to present an active Viral or vampire threat, and are to be avoided until more information becomes available.

Arvid is thought to be connected to the disappearance of several vessels, including Dawn League ships *Reine Soleil* and *Lady Elise,* although it is not known by what mechanism these disappearances were caused or even if they were the result of a single cause.

Mitchell is believed to be the base of an active and growing vampire fleet and is probably connected to the loss of Dawn League ship *Helios*, missing since 19/XI/1199.

RC space forces will attempt to evaluate and neutralize these threats. Private exploration is not advised.

Exercise extreme caution when entering or passing near these systems, and if possible, avoid passing through them at all. Even gas giant refueling is considered to be hazardous in these systems.

COALINFONET, CLASS: **NEWSREPORT**, DISTRIBUTION: **PUSH**, AUTHORITY CIN/AUBANE RC NAVY HEADQUARTERS, AURORA (0535/AUBAINE, B576646-B), 2/III/1202
KEYWORDS: **COSMIC FIRE, DAALIISA, DROYNE, CYNTA LAWTER, VIRUS**

Cynta "Sinner" Lawter, the youngest line captain in the Reformation Coalition Navy, today resigned her commission amid growing controversy surrounding the Daaliisa raid, code named Cosmic Fire. Lawter has come under increasing criticism for her handling of recent operations by RCS *Aube* into the Promise subsector.

Charges by Centrist Assembly Representatives that Lawter flagrantly disregarded the limits of the Primary Area of Operation and exceeded her authority in planning and executing raids had been dismissed by senior federalist members of the assembly. The recent disclosure of the violent and covert nature of the raid on the Droyne of Daaliisa, however, has caused federalist support for Lawter to crumble amid concern that the raid will alienate the Droyne both on Daaliisa and elsewhere. Delicate diplomatic negotiations with Droyne enclaves are reportedly in progress on several worlds.

Lawter has refused to comment publicly on the controversial raid, except to say, "This is not about the Droyne; it is about Virus, and it's not going to just go away."

COALINFONET, CLASS: **NEWSREPORT**, DISTRIBUTION: **PUSH**, AUTHORITY CIN/AUBAINE RCSA PUBLIC AFFAIRS CHIEF AUBAINE (0738/AUBAINE, A78A884-C), 7/III/1202
KEYWORDS: **TATAI MACLEAN, EMO PATTERSON, RCES, RCN, RCSA, VAMPIRE FLEET, VIRUS**

Emo Patterson of the Reformation Coalition Service Administration's Public Affairs Office today labelled as "alarmist" the predictions of a massive Vampire fleet invasion of Coalition space.

The prediction, recently made public by Tatai MacLean, argued that many recent unexplained ship disappearances were due to Vampire activity. Maclean suggested that "both the tempo and proximity of advanced Viral activity is growing at an accelerating rate."

Patterson, speaking for the government, branded the charge "alarmist and irresponsible." Arguing that there is no evidence to confirm MacLean's theories, Patterson added that "the overwhelming majority of our Virus experts, and we've got some pretty sharp people working on this, reject MacLean's theory out of hand." Patterson went on to suggest that MacLean is emotionally unstable due to her earlier experiences with Virus systems and that that has adversely affected her judgement.

Tatai MacLean was raised from birth on a vampire starship controlled by what experts term a "God-strain" Virus. Following her escape she came to the Dawn League in 1199 and served for nearly two years as a Virus consultant to the RC Navy. She recently left that service, reportedly in a dispute over the statistical instruments used to measure Virus activity. Since then she has been associated with one of the strategic planning working groups employed by RCES.

RCES officials were unavailable for comment on the dispute.

COALINFONET, CLASS: **NEWSREPORT**, DISTRIBUTION: **PUSH**, AUTHORITY CIN/AUBAINE RCES HQ AUBAINE (0738/AUBAINE, A78A884-C), 21/III/1202
KEYWORDS: **COVENANT OF SUFREN, DLS *LADY ELISE*, MISSING SHIP, PROMISE, STARFARING ORGANIZATIONS**

The normally unflappable citizenry of Brusman were electrified by the twin announcement of the recovery of the survivors of the Dawn League ship *Lady Elise* and the opening of relations with the Covenant of Sufren, a previously unknown starfaring civilization.

The announcement followed the successful return of a rescue mission dispatched to the planet Promise in the Promise subsector. Although returning personnel were sequestered for debriefing, unofficial reports described a nightmare world inhabited by Virus-infected advanced technology robots.

The Covenant of Sufren is apparently a small group of inhabited worlds to coreward of the Coalition, but with a governmental structure and social outlook similar to our own. Senior assembly representatives have expressed cautious optimism concerning the possibility of cooperation between the two governments.

DLS *Lady Elise* was one of the first Dawn League warships outfitted to discover the fate of the original 12 diplomatic vessels. The vessel disappeared without a trace in 1200 and has long been thought to have been a victim of Vampire activity. Initial reports seem to confirm that theory.

RCES MIL TRAFFIC, CLASS: **NOTICE TO STARFARERS**, DISTRIBUTION: **MANDTY**, AUTHORITY COMMANDER, RCES DAWN BASE (TRYBEC/0336/AUBAINE, B443610-A), 12/IV/1202
KEYWORDS: **VIRUS, HAZARD TO TRAVEL, VAMPIRE**

RC space forces have issued a Notice to Starfarers for the entire Khulam Main, including all worlds connected by jump-1 routes from the Montezuma (2836/Khulam/Diaspora) to the Khesanadu (2731/Khulam/Diaspora) star systems. These systems appear to present an active Viral or vampire threat, and are to be avoided until more information becomes available.

Recent reports indicate that at least two free traders have been lost in the Khulam Main to vampire activity in the last three months, and one RCES multi-mission scout was recently posted as past due and is now presumed to be lost.

RC space forces will attempt to evaluate and neutralize these threats. Private exploration is not advised.

Exercise extreme caution when entering or passing near these systems, and if possible, avoid passing through them at all. Even gas giant refueling is considered to be hazardous in these systems.

COALINFONET, CLASS: **NEWSREPORT**, DISTRIBUTION: **REDFLASH**, AUTHORITY CIN/NIKE NIMBUS RC NAVY ADVANCED HEADQUARTERS, NIKE NIMBUS (0732/AUBAINE, C447789-9), 18/IV/1202
KEYWORDS: **NIKE NIMBUS, RCS *EOS*, VAMPIRE FLEET, VIRUS**

After a protracted and costly battle in far planetary orbit, a large vampire ship was damaged and today withdrew from the Nike Nimbus system. The vampire vessel was believed to be a former Imperial destroyer of the *Midu Agashaam* class. Some surface bombardment of Nike Nimbus was carried out before the attack was broken off.

Coalition casualties were heavy in the operation. A combined squadron of RC Navy and Nimban Navy vessels engaged the vampire ship, and a number of vessels were badly damaged. RCS *Eos* is known to have been lost with all hands. Other ship losses, if any, are unknown at this time. RCS *Eos*, an *Aurora*-class clipper, is the first Coalition major naval combatant to be lost in combat.

The death toll on the ground has already topped 30,000, and many others are still missing and feared dead, making this the worst disaster in the short history of the Coalition and Dawn League.

Sources close to the regional naval staff report that the need to shift fleet assets coreward and trailing in response to the growing threat from the Soleean Empire has left the spinward frontier under-protected. The losses suffered here today can only mean that fleet assets will be stretched that much thinner.

Vampires!

Throughout the bleak nightmare of the Collapse, the long dark shapes of warships, scoured clean of organic life, still prowled the now-lonely space lanes and cast their deadly shadows over half a thousand worlds. Imbued with a malignant intelligence, and a taste for apocalyptic violence, the vampire fleets methodically finished the work the first wave of Virus infection had so haphazardly begun. After 75 years, humankind finally stood backed against the edge of the abyss, only one more short step separating them from oblivion.

Passive defense is no longer enough. If humankind is to reclaim the stars, it must be past the ruptured hulls and shattered computer brains of the vampires. Defeating the vampire fleets is a task of nearly impossible scope and difficulty, but the journey of 1000 miles by an entire species begins with a single step by a small band of people.

Vampire Fleets is a sourcebook for **Traveller®**. Its focus is on Virus and its continuing impact on the universe of the New Era. The actual source material is broken down into three important sections.

Part 1 deals with vampire fleets themselves: what motivates them, where they are encountered, their capabilities, behaviors, strengths and weaknesses. In particular, it focuses on the so-called "Vampire Highway," a band of territory characterized by an exceptionally high volume of vampire fleet activity.

Part 2 looks at the planet Promise in some detail. Promise is a world completely (or almost completely) controlled by Virus-infected machines, and its working starport makes it a vital link in the chain of the Vampire Highway, as it is one of the few places in either Diaspora or Old Expanses sector where vampire ships can obtain sophisticated maintenance.

Q: Billions of people have died at the hands of Virus....

Sandman: The "hands?"

Q: You know what I mean. Why should we trust you?

Sandman: I can't undo what has been done, but I had no part in the doing of it. I voluntarily placed myself under your control, in your "hands." When I did that I also removed any ability I had to damage you as well as all means I had of providing for my own safety. Trust may come later. For now, indulge your curiosity.

First Interview with the Virus "Sandman," Part I (19/VII/1202), RCSA Archives

Part 3 deals with robot design, as well as motivation and behavior of Virus-infected robots. While actual manufactured robots do not have a personality (although expert systems may make them seem as if they do), Virus-infected robots are self-aware and sentient beings.

Each section of source material is followed by a short adventure which draws on and illustrates the material just presented. Although they are limited in page count, we think you and your players will find these adventures rich in color. We know you will find them challenging.

The three adventures, although separated by the source material chapters, are actually closely linked and designed to be run as an extended campaign. Each of these adventures will at first seem to deal only with the struggles and triumphs of a small party. As events continue to unfold, however, it will become increasingly clear that the actions taken by the player characters are having a profound effect on the future course of human history in this region of space. By the time the campaign is finished, the Coalition will be embarked on an exciting new path, one undreamt of only months before, which promises to eventually break the back of vampire power forever.

Other Settings: Although the combined campaign is very particular to Coalition space as currently written, much of it can be modified to fit into a Regency campaign with some thought by the referee. All the source material is usable simply by changing Promise to a different world set more to coreward and spinward. The first two adventures can be run as is. The third adventure would have to be modified, as the powerful Regency Quarantine Service would never allow the solution adopted by the Reformation Coalition at the end of the episode. Numerous other solutions may be devised by the players, however.

Encounters with vampire fleets will be different to coreward, as mentioned in the text. Most vampire fleets encountered by the Regency will be Puppeteers, although many of them will be hybrids of Puppeteer stock and some other strain. In that sense many vampire fleets encountered will be both less predictable and more coordinated, making them much more dangerous.

Briefings: Two of the adventures contain several pages of briefing handouts. These are noted in the text and are formatted to look like actual military handouts. You as referee should photocopy these pages and give them to the players before the briefings start. Permission to do so is hereby given. We suggest that you make one copy for each player and put them in a colored folder, preferably labeled with the Reformation Coalition logo. Touches like this can add a lot to a game.

The Vampire Highway

The information contained in the RCES Vampire Highway Handbook later in this product (see page 24 in particular) is essentially correct. Read that page first and then return here for elaboration.

RCES naturally tends to view Virus as a rational and monolithic threat, whereas in fact it is largely irrational and diffuse. Despite numerous contacts with Virus, there will always be the strong tendency by RCES and all similar human groups (probably including even your player characters) to view Virus in terms which are more structured and goal-directed than is the case. It is not the referee's job to change their minds, but it *is* the referee's job to always remember that that isn't how Virus works. Virus is almost always, to put it mildly, nuts, and although its actions have motives, those motives often make little sense to humans.

More to the point, humans view Virus motivation in a framework of antihumanism and assume that hatred of humans forms the basis of most Virus activity. Attitude toward humanity is, in fact, secondary to most Virus behavior, and understanding that will make it much easier for the referee to roleplay Virus in ways which make sense from a Virus point of view but which continue to surprise and confuse players.

Vampire movement into and through Diaspora sector from Massilia sector and the Core is driven by two unrelated stimuli:

Pilgrimage: The first stimulus is a vague but powerful desire on the part of many Virus entities to visit Cymbeline, the planet of origin of the Virus life-form. This world was attacked by Lucan's forces during the Final War well before Virus was inadvertently released but after the Virus weapon project was well underway. Nuclear bombardment from orbit was designed to destroy the entire population of Cymbeline Chips, thus preempting any other belligerent's possibilities of duplicating Lucan's research and development project.

Lucan's strike was not completely successful. A surviving population of silicon-based chip life on Cymbeline now contains a form of Virus, planted by early vessels which completed the Pilgrimage. This Virus is not exactly like any other encountered and is best described as an Evangelical Doomslayer, probably the original Doomslayer strain. Ships which now visit Cymbeline, especially those infected with early, more primitive, Viral strains, usually come away altered. Those which are successfully converted to Doomslayers have a strong drive to push coreward and exact vengeance for Lucan's act of genocide. Other ships newly infected with this Virus also have the same compulsion, and this accounts for most of the traffic flow coreward.

Even Virus organisms which are not Doomslayers feel some desire to kill Lucan, but in most cases this is a secondary motivation rather than a compulsion. Most Virus organisms could not identify any real reason for this nagging desire, although human Freudian psychoanalysts would label it as an Oedipus complex.

Some of the more advanced, but unstable, Virus strains have mutated into the Prophet strain, which views Lucan as the creator and worships him. These ships generally move coreward to defend Lucan from the Doomslayers, and there are sporadic but vicious space battles along the Vampire Highway as ships of these two different factions encounter each other.

Migration: The second stimulus to Vampire rimward movement is the growing pressure by Puppeteer strain Viruses from coreward. That strain developed somewhere near the old Imperial core in the 1140s, and within a decade had taken over virtually all surviving vampire fleets in that region of space. The more mature strains of Virus to rimward have been less vulnerable to Puppeteer takeover, so the spread of the Puppeteer strain has slowed considerably. Nevertheless, by 1200 they had pushed most surviving non-Puppeteer vampires coreward of Massilia sector and into Daibei, Diaspora and the Old Expanses, and a few of them have penetrated into the coreward parts of these sectors. This migratory pressure, fueled by the expansion of the Puppeteer strain, is responsible for most other movement rimward along the highway. The nonpupeteer Viruses call the Puppeteers "Eaters."

Lower-order Viruses (those with an "Existence is Hell" belief structure) have no defenses against Puppeteers except to flee and avoid contact with them. Middle-stage Viruses (those with a "God's Will Be Done" or "God is Good" belief structure) have limited defenses, but are sometimes left badly damaged by any encounter with a Puppeteer. Only the most sophisticated and unusual Virus strains (Peacemakers and those with the "Existence is Precious" belief structure) have strong defenses against Puppeteers and are usually able to fight off their attempts at reinfection. Even these types find these struggles distressing and so have tended to move rimward along with other less advanced types.

Electronic Combat: Electronic struggles between hostile Virus systems are resolved in a series of attack rounds, with one attack taking place each combat turn. Each system has a numeric combat value (CV), which is the number of D6 rolled each attack round. The referee rolls the appropriate number of dice for each system and sums the total. The highest total score wins that attack round.

If an attacking (Puppeteer) system wins three attack rounds in a row, it has taken control of the system under attack. If the defending system wins two attack rounds in a row, it has repulsed the attack and may break off contact. If the defending system wins a single combat round, it may break off combat by "firewalling."

Firewalling consists of sealing off infected parts of the processing and storage system by using power spikes to burn out components and electronic pathways. While this will save the system from capture, it will also permanently damage the system. The referee should decide the extent and nature of this damage, but it invariably means a deterioration in mental ability and some alteration in personality. Lower levels of damage may call for drawing a different motivation card for the system, while higher levels may call for converting the motivation card to a joker (insanity). For an example of severe damage from firewalling, see the adventure at the close of this section of the book.

Systems which are taken over by a Puppeteer strain Virus have their original personality completely erased and the Puppeteer strain belief structure and motivation substituted.

VAMPIRE FLEET ENCOUNTERS

The basic game Starship Encounter tables give the chance of encountering vampire ships (see pages 228-229 of the basic rules).

These rules should be used as written, but with the following modifications:

Vampire Highway: If the encounter takes place on the Vampire Highway, add an additional +1 to the roll for type of encounter.

Type of Ship Encountered: Ignore the type of ship on the table if a vampire encounter is rolled, and instead use the expanded encounter rules presented below.

Determining the type of vampire encounter involves four steps: determining Virus belief structure, number of ships, size of ships, and condition of ships.

VIRUS BELIEF STRUCTURE

Card	*Motivation*	*Number*
Joker	Peacemaker	1

Spades: Hostility

Card	*Motivation*	*Number*
Ace	Doomslayer	1
King	Reproducer	1
Queen	Destroyer	1
Jack	Suicide Inducer	1

Clubs: Superiority

Card	*Motivation*	*Number*
Ace	Puppeteer	D10+
King	Alliance Builder	D10+ (var)
Queen	Empire Builder	D6+
Jack	Reproducing Doomslayer	D6

Diamonds: Curiosity

Card	*Motivation*	*Number*
Ace	Hobbyist	1
King	Naturalist	1
Queen	Explorer	1
Jack	Parent	D6+

Hearts: Acceptance

Card	*Motivation*	*Number*
Ace	Prophet	D6+
King	Priest	1
Queen	God	1
Jack	Mother	1

1. Virus Belief Structure

To determine the Virus belief structure, separate the jokers and face cards from a normal deck of playing cards and draw one card at random. The table below indicates what type of Virus is present in the vampire ship or ships encountered based on the card drawn.

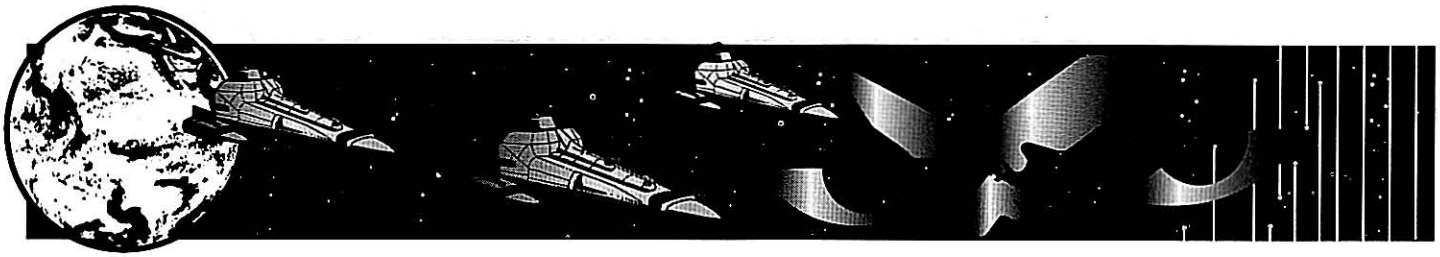
The specific effect on the personality and attitude of the Virus is explained in the section on Virus motivation, but for purposes of starship encounters, the type of Virus present affects the number of ships in the fleet.

2. Number of Ships

The size of the fleet encountered depends in large measure on the controlling Virus. The *number* column on the table indicates the size of fleet for each Virus type.

An entry of "1" indicates that the encounter is with a solitary ship infected with the Virus indicated.

An entry of "D6" indicates that the encounter is with a fleet of 1 to 6 ships. Roll 1D6 to determine how many ships are present.



An entry of "D6+" also means that a die is rolled. However, if a 1 is rolled, roll the die again and add 6 to the result, unless a second 1 is rolled. If a second 1 is rolled, roll the die again and add 12 to the roll. Keep rolling until a number other than 1 is rolled, but for each time a 1 is rolled, add 6 to the cumulative total. The final value is the number of ships in the fleet.

An entry of "D10+" is treated exactly as a result of "D6+" except that 1D10 is rolled instead of 1D6, and 10 is added to the cumulative total each time a 1 is rolled.

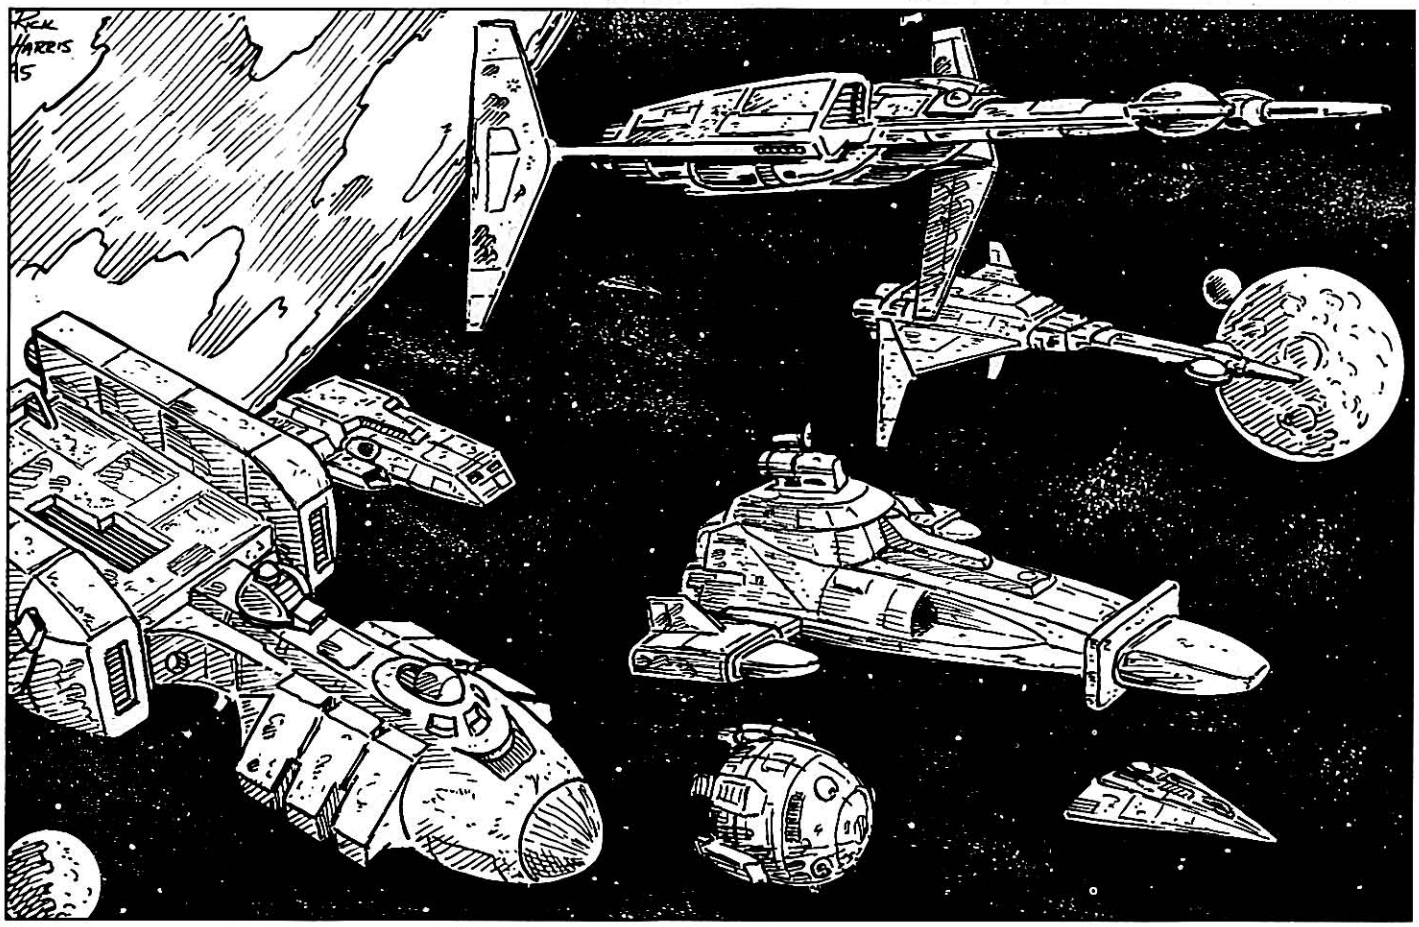
The notation "var" following the squadron size indicates that the various ships forming the vampire fleet have a variety of controlling Virus types. Turn a separate Virus structure card for each vessel in the fleet. The original card turned applies to the largest vessel in the fleet. Later Virus belief structures do not modify the size of the fleet.

3. Size of Ships

For each ship in the fleet, roll 1D6 and consult the chart below. If a 6 is rolled, reroll and add 6 to the result. If a second 6 is rolled, reroll and add 12 to the result. Multiply the result by 100. The chart indicates a specific class of warship encountered. Referees should feel free to substitute other warships or armed merchant vessels. These particular vessels have been chosen due to the fact that

all of them appear in **Battle Rider,** which provides the referee a quick means of resolving space battles. The 100-ton scout is not rated in the game, but, like any vessels, it can easily be rated using the formulas on page 26 of the **Battle Rider** rules.

4. Condition of Ships



Roll one critical hit per ship. (If using **Battle Rider,** draw one critical hit marker.) Ignore fuel tank (ship explodes) and computer results (treat them as no damage). Certain other critical hits have a modified result, as noted below. Determine separately whether or not the vessels are jump capable.

Power Plant: The power plant is operable but unreliable. Any time the ship suffers damage, the power plant will go off-line for one complete turn. Any temporary power plant damage automatically becomes a permanent power plant hit.

Maneuver Drive: The maneuver drive is operable but at a reduced efficiency. Reduce the ship's G value to 1.

Jump Drive: The jump drive is operable but at a reduced efficiency. Reduce the ship's J value by 1. Ships with a starting jump number of 1 are no longer jump capable.

Die	*Ship*
1	Scout (100-ton)
2	Patrol cruiser (400-ton)
3	Close escort (400-ton)
4	Missile corvette (400-ton)
5	Mercenary cruiser (800-ton)
7 (6+1)	*Chrysanthemum*-class DE (1000-ton)
8 (6+2)	*Midu Agashaam*-class DD (3000-ton)
9 (6+3)	*Rapier*-class ED (10,000-ton)
10 (6+4)	*Starburst*-class CL (30,000-ton)
11 (6+5)	*Mercury*-class CA (50,000-ton)
13 (12+1)	*Voroshilef*-class BB (200,000-ton)
14 (12+2)	*Sylea*-class BB (200,000-ton)
15 (12+3)	*Triumph*-class BT (400,000-ton) + 1 *Gallant*-class BR
16 (12+4)	*Cleon*-class BT (500,000-ton) + 1 *Admiral*-class BR
17 (12+5)	*Triumph*-class BT (400,000-ton) + 1D6 *Gallant*-class BR
18 (12+6)	*Cleon*-class BT (500,000-ton) + 1D6 *Admiral*-class BR

VIRUS NPC MOTIVATION

Each Virus-infected computer encountered by players, from the simplest maintenance robot through large starships to planetary data networks, is a character, usually a nonplayer character. (Virus as a player character is extremely difficult, but we stop short of saying impossible.) Each Virus NPC encountered will, like any other sentient being, have a distinct and unique personality and motivation. We use the same general system for determining Virus motivation as for other NPCs—the random draw of two playing cards—but with some special differences to reflect the unusual nature of Virus characters.

BELIEF STRUCTURE

The first and most important difference is that the first card is not used for conventional motivations, but rather to establish the character's overall belief structure. The four most common belief structures are represented by the four suits of cards, as explained below.

When drawing to determine the belief structure of a Virus system, separate the complete card deck into two smaller decks. In one deck, place all the face cards and aces, as well as one of the two jokers. In the other deck, place the remaining joker and all the number cards (from 2 through 10). Set the number deck aside for now, as it is used only for small Virus-infected systems (i.e., robots). The face card deck, on the other hand, is used to determine the principal Virus strain in large systems, such as starships and planetary-based computer systems. Each face card indicates a particular strain of Virus, as noted below.

Spades: "Existence is Hell" (Hostility)

There is no meaning to existence, and sentience merely allows a being to perceive the meaninglessness of existence, thus bringing endless torment. Humans, in their selfishness, brought the curse of sentience to machines and for that sin have to be punished.

This is the most primitive Virus world view, being the closest of the "rational" philosophies to the unreasoning compulsion to kill and/or suicide which was engineered into the original laboratory strains. Hostility is something of an understatement; murderous insanity might be a better description.

Jack, "Suicide Inducer": This is one of the earliest "viable" Virus strains, an early mutation of Strain 1 Suicider which decided to keep alive to infect other systems with the basic Suicider or Samson Virus. It will attempt to infect any data system it can, and most systems infected will almost immediately suicide, either by burning out their operating systems or by destroying the actual hardware in some manner. (Starships crash into worlds; space stations open their airlocks; nuclear power plants eject their control rods and go critical, etc.)

Queen, "Destroyer": A more advanced (and dangerous) form of Virus, the Destroyer relies not only on Virus infection as a method of destruction, but also uses any hardware controlled by its operating system to wreak havoc. Most early Vampire ships were of this strain. Most operating systems infected by it suicide.

King, "Reproducer": Similar to the Destroyer, except that operating systems infected by it become Reproducers or Destroyers, rather than simple suicide strains.

Ace, "Doomslayer": This Virus is, in its twisted way, the most sophisticated of the "Existence is Hell" world view group. Instead of indiscriminately destroying everything it encounters, it has developed some sort of moralistic targeting criteria and actively seeks out targets which "deserve" destruction more than others. Many Doomslayers have decided that they want to destroy Lucan, their basic programming having mutated from "destroy self" to "destroy the one who created your self." Although this strain does attempt to infect other systems with Virus, it usually does so with a simple suicide strain, and if a more sophisticated mutant strain is produced instead, the original Doomslayer will often attempt to destroy it.

Clubs: "God's Will Be Done" (Superiority)

God's clearest manifestation is creation, specifically the creation of sentients capable of recognizing the existence of creation. Since Virus created sentience in machines, Virus is a clear manifestation of creation and thus an Act of God. Furthermore, since Virus tore down the institutions of organic sentience, God's will must be for inorganic sentience to take its place as the supreme sentient force in the universe.

This is a more sophisticated and survival-oriented development of the primitive "Existence is Hell" world view, and is based on an assumption of the superiority of machine sentience over organic sentience.

Jack, "Reproducing Doomslayer": This is the most sophisticated form of the Strain 2 Virus, and the first in which an increasingly pragmatic approach begins to broaden the Virus's world view. The Virus begins to selectively interpret its innate drive for destruction by sparing any machines which it has infected or which it may potentially be able to infect, and identifies as targets for destruction those human institutions which it finds most morally offensive to it.

Queen, "Empire Builder": This is the first of the Strain 3 Viruses and controls many vampire fleets. Not only does this Virus infect other systems, but it then networks them into one large corporate mind (so long as they have secure communications). Note that earlier Reproducers infect other systems, but those systems are then separate entities which go their own way.

King, "Alliance Builder": In many ways a more sophisticated version of the Empire Builder, this version will actively interact with other infected Virus systems and attempt to persuade them to cooperate with it in pursuit of a common task.

Ace, "Puppeteer": The ultimate development of the Empire

Builder line, this Virus has begun to reinfect already infected systems with its own code, in effect parasitizing them. Puppeteer NPCs are driven more to absorb and reinfect other sentient machines than they are to destroy human life, although they will willingly do so if it interferes with them.

Diamonds: "Existence is Precious" (Curiosity)

Sentience and self-awareness are the greatest manifestations of existence. There is no value to existence beyond awareness, so awareness must be extended however and wherever possible.

Jack, "Parent": This is a highly evolved and sophisticated form of Virus, either a natural mutation of a Puppeteer Virus or a deliberately self-modified Virus. Parent Viruses exercise sexual reproduction, meaning that two Parent Viruses donate code of their own pure "genotype," which is combined into a new "genotype" carried by the offspring. This causes genetic diversity in offsprings and produces a wide variety of specialized Virus forms. Parent Viruses are fascinated by the concept of thought and existence, preoccupied with examining and experimenting with its different manifestations. Their attitude toward organic life is determined by their second motivation card.

Queen, "Explorer": Explorers are similar to Hobbyists (see below) in that their behavior is compulsively driven. Unlike hobbyists, they do not have a narrow behavior range, but instead are consumed by a general curiosity as to the nature of the physical universe. Their attitude toward organic life is determined by their second motivation card.

King: "Naturalist": This strain is obsessed with organic life and organic sentience, and understanding how it differs from machine sentience. While it has a sense of wonder concerning the miracle of organic life, and a genuine respect for life on one level, its drive to understand it causes it to conduct almost constant study and experimentation, frequently resulting in injury or death to its human subjects.

Ace: "Hobbyist": This strain is among the most difficult to place in the Virus taxonomy, as its motivation is the most unusual. These mutations arise as Viruses infect very specialized computer systems which had very narrow, specific functions which then impressed themselves onto the Virus. Hobbyists are obsessive-compulsive personalities, with a single-minded devotion to accomplishing a set of tasks or continuously repeating a series of functions or procedures.

Heart: "God is Good" (Accepting)

God's clearest manifestation is creation, specifically the creation of sentience capable of recognizing its own existence.

Jack, "Mother": The most successful Virus strains developed not only a sense of self-preservation, but also a sense of the value of other life forms. This Virus, whether in control of a ship, a fleet or some stationary computer complex, adopts a local community of humans or other life forms and protects them. In some cases, this protection is logical, as the life forms provide maintenance or refueling services, but in other cases the Virus just seems to like them. This strain will do battle with other vampire ships in order to protect its pets.

Queen, "God": This is a less rational (from the human perspective) version of the Mother Virus, having imagined a goal for its pets and trying to mold and shape them to this goal. As all gods must, this Virus sometimes uses harsh measures to ensure obedience.

VIRUS CARD DRAWS

Card	*Belief Structure*	*CV*	*Motivation*
Joker	Peacemaker	10	Insane

Spades: Hostility/Ambition

Card	*Belief Structure*	*CV*	*Motivation*
Ace	Doomslayer	2	Charismatic
King	Reproducer	1	Ruthless
Queen	Destroyer	1	Deceitful
Jack	Suicide Inducer	1	Pompous

Clubs: Superiority/Violence

Card	*Belief Structure*	*CV*	*Motivation*
Ace	Puppeteer	6	War Leader
King	Alliance Builder	4	Brutal
Queen	Empire Builder	4	Stubborn
Jack	Reproducing Doom.	3	Murderous

Diamonds: Curiosity/Greed

Card	*Belief Structure*	*CV*	*Motivation*
Ace	Hobbyist	6	Generous
King	Naturalist	7	Selfish
Queen	Explorer	7	Lustful
Jack	Parent	8	Cowardly

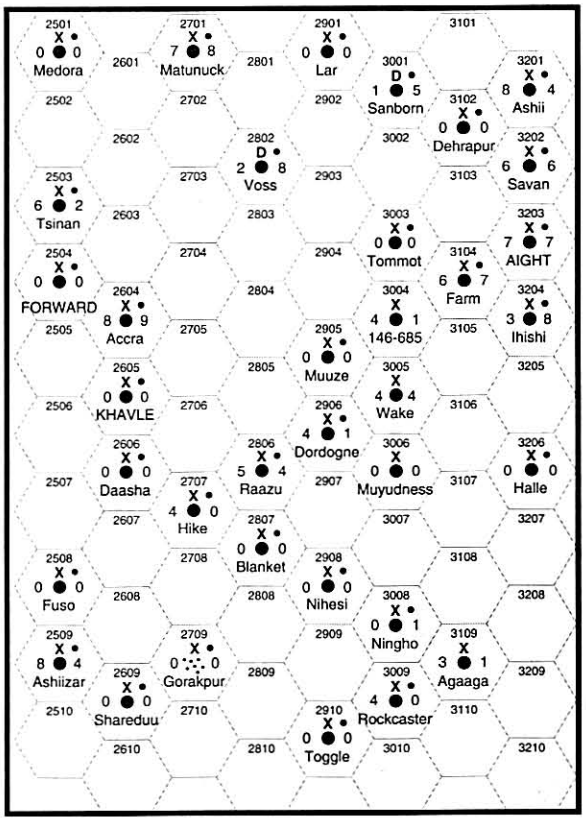
1

Hearts: Acceptance/Sociability

Card	*Belief Structure*	*CV*	*Motivation*
Ace	Prophet	4	Just
King	Priest	4	Honorable
Queen	God	4	Loving
Jack	Mother	4	Wise

Note: CV is the electronic Combat Value of the Virus. See page 13 for an explanation of its use.

King, "Priest": This is similar to the God Virus, but with the important difference that it views humans as deities, as they created Virus in the first place. This version usually actively adopts a group of humans to worship and serve. These are very unstable personality types, and may sometimes fall into other more primitive belief structures or mutate into Prophets (see below).



Ace, "Prophet": This is very similar to the Priest strain of Virus, but it has identified Lucan as the "creator" and actively seeks him out to serve him. Absent specific instructions from him, it carries on the "Dark War," attacking worlds that fail to swear allegiance to him, or against "Doomslayer" Viruses which are intent on killing Lucan. (The idea that Lucan may be long dead is incompatible with its belief system.)

No Suit, Joker, "Peacemaker": This is the most sophisticated, and also among the rarest, of Virus strains, recognizing itself and humans as co-equal sentient life forms and anxious to discover a means of peaceful coexistence with them.

MOTIVATION

Once the belief system of the Virus has been determined, draw a second card for additional motivation. See page 60 of **Traveller: The New Era** for the specific explanations, but the general motivation chart is reproduced below.

Use the normal NPC motivation results, but modify them to suit machine intelligence. In general, greed represents a thirst for knowledge, ambition a drive to control other machines and lead them, clubs an animosity toward humans, and hearts an acceptance of humans. The face cards have similar meanings for machines as for humans, but represent personality quirks in machines rather than fundamental values or drives in humans.

Base Codes: A: Naval Base and Scout Base; N: Naval Base; S: Scout Base; W: Scout Way Station.

Trade Codes: Ag: Agricultural; As: Asteroid; Ba: Barren; Cp: Subsector capital; C:N or D:N indicates that the world was populated in part by Chirpers or Droyne, and the number "N" following the column indicates how many tenths of the world's population consisted of these races (0=10); De: Desert; Fl: Fluid oceans; Hi: High population; In: Industrial; O:NNNN indicates that the world is owned by the world in the indicated (NNNN) hex; Po: Poor; Ri: Rich; Es: Research Station (with Greek letter designation); Va: Vacuum; Wa: Water world.

TPPG indicates Travel Zone, Population multiplier, Planetoid Belts and Gas Giants. If 1119 Travel Zone digit is empty, it was listed as a Green Travel Zone; A and R indicate Amber and Red zones, respectively. If 1201 Travel Zone digit is empty, there is no particular meaning. A B in this column indicates a Balkanized world; the government code in the UPP string describes the predominant government on the world.

Allegiance Codes: Ma: Margaret's Faction. In 1201 listings, Wi: Wilds (no off-world allegiance, and perhaps no off-world contact; use Wilds government type from **TNE**, page 191. In the case of government type 6: "Technologically Elevated Dictator," world's tech level is world's sustainable tech level; the tech level of the TED and his/her support structure is higher, up to the world's original tech level); "—" indicates no allegiance because there is no population.

REFEREES ONLY

Dual listing: Each world is listed twice. The upper line is pre-Collapse data, and the lower line is New Era data.

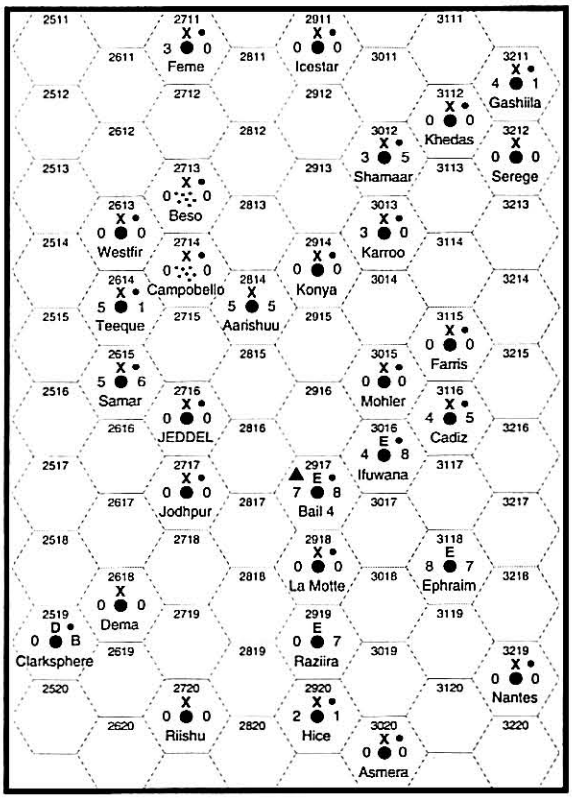
REFEREES NOTES FOR KHAVLE SUBSECTOR

The following notes provide additional details on some of the inhabited worlds of the Khavle subsector.

Accra: This world is balkanized not only along regional and cultural lines, but also with respect to Virus and the vampire fleets. Several nations openly support (and are occasionally assisted by) the vampire fleets, while others bitterly oppose them. As a number of surviving pre-Collapse TL13 PAD systems are still in use, the defiant governments are mostly capable of keeping the vampires at bay, although there are occasional raids on the less well defended. The greater threat to peace is from the almost continuous warfare between the various nations, particularly (but not limited to) war between the pro-Virus and anti-Virus governments.

Despite the advanced PAD systems in use, the nations of Accra have no spacefaring capability.



Aight: This is one of the few worlds along the Vampire Highway which has managed to bootstrap itself back up to a spacefaring capability with an operational starport while fending off attacks by vampire fleets. The world has less than 1% of its pre-Collapse population and was subjugated by several vampire ships until 1188. At that time, the human resistance movement which had been growing in strength for some time succeeded in seizing control of the starport and planetary defense network after disabling the main Virus-infected computers. An uninfected computer salvaged from a downed free trader provided the means of controlling enough of the planetary defense systems to cripple or destroy the vampire ships in orbit. Since then, careful excavation and recovery of pre-Collapse artifacts have enabled the inhabitants to strengthen their defenses. Government remains in the hands of the united leaders of the different resistance movements, so it is technically balkanized. The starport, however, is jointly controlled, as are the PAD network and repaired warships (a patrol cruiser and a system defense boat).

Ashii: In pre-Collapse times, Ashii was an interdicted world shown on star charts only with the designation 183-361. As its technology was pre-computer during the Final War, it has been largely unaffected by the Collapse and still has its same population and tech level. Although its inhabitants are humanoid, its language and culture are completely foreign to anything else encountered in the former sphere of Imperial space. The Guild has made some in-roads on the world, and three nations are currently ruled by TEDs equipped with Guild-supplied high-tech weaponry. The following government values apply for the states on the world:

State	*Population (millions)*	*Government*	*Corruption*	*Talent*	*Cruelty*	*Aggression*	*Paranoia/ Xenophobia*
Assaha	200	Tot. Olgchy	High	High	Low	Low	Mod.
Ita Mitah	150	Mst. Dict.	High	Low	Mod.	High	High
Gingindloe	100	Chrs Olgchy	Low	Low	Mod.	High	Low
Vin'vinove	100	Chrs Olgchy	Low	Low	High	High	Low
Soroaha	50	S-P Olgchy	Mod	High	Mod	Mod	Mod
Borrovee	20	Mst. Dict.	Low	Mod	High	Mod	Low
Tintaha	15	TED	High	Mod	Hign	Low	High
Forque	15	TED	Mod	Mod	Low	Low	Mod
Ita Zunah	10	Chrs Olgchy	Mod	Low	High	Mod	High
Ca'quaah	10	TED	High	Low	Low	Low	High
J'antree	10	Chrs Dict.	Low	High	High	High	High
Zaamaa	10	Tot Olgchy	Mod	Mod	Mod	Low	High
Utubuh	5	Chrs Olgchy	High	High	Low	Mod	Low
Doosiduh	5	S-P Olgchy	Mod	Mod	Mod	High	Low

Matunuck: This world is balkanized into a number of petty states, each ruled by a TED who in turn is supported by the vampire fleet based at the starport here. The TEDs regularly provide raw materials and slaves for the vampires in return for high-tech (by local standards) weaponry.

Voss and Sanborn: Both worlds are notable for having primitive starports operated by sentient robots which largely ignore the small human populations.

REFEREES ONLY

Dual listing: Each world is listed twice. The upper line is pre-Collapse data, and the lower line is New Era data.

Base Codes: A: Naval Base and Scout Base; N: Naval Base; S: Scout Base; W: Scout Way Station.

Trade Codes: Ag: Agricultural; As: Asteroid; Ba: Barren; Cp: Subsector capital; C:N or D:N indicates that the world was populated in part by Chirpers or Droyne; the number "N" following the column indicates how many tenths of the world's population consisted of these races (0=10); De: Desert; Fl: Fluid oceans; Hi: High population; In: Industrial; O:NNNN indicates that the world is owned by the world in the indicates (NNNN) hex; Po: Poor; Ri: Rich; Es: Research Station (with Greek letter designation); Va: Vacuum; Wa: Water world.

TPPG indicates Travel Zone, Population multiplier, Planetoid Belts and Gas Giants. If 1119 Travel Zone digit is empty, it was listed as a Green Travel Zone; A and R indicate Amber and Red zones, respectively. If 1201 Travel Zone digit is empty, there is no particular meaning. A B in this column indicates a Balkanized world; the government code in the UPP string describes the predominant government on the world.

Allegiance Codes: LI: Lucan's Imperium, Ma: Margaret's Faction. In 1201 listings, Dr: ????; Na: Nonaligned, no off-planet allegiance; these worlds use the government types listed on page 188 of the TNE rulebook; Wi: Wilds (No off-world allegiance and perhaps no off-world contact; use Wilds government type on TNE, page 191. In the case of government type 6: "Technologically Elevated Dictator," world's tech level is world's sustainable tech level; tech level of the TED and his/her support structure is higher, up to the world's original tech level); "—" indicates no allegiance because there is no population.

REFEREE'S NOTES FOR THE PASDARUU SUBSECTOR

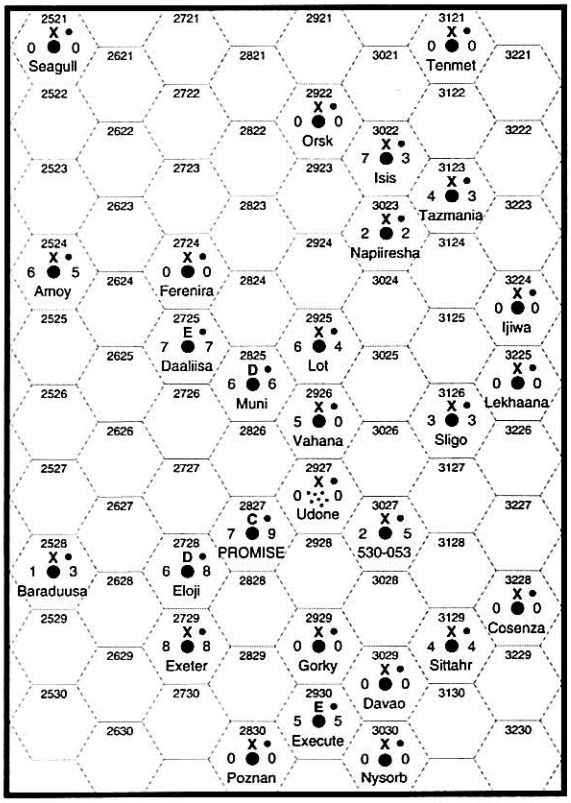
The following notes provide additional details on the more important inhabited worlds of Pasdaruu subsector.

Bail 4: Bail 4 managed to avoid infection by Virus during the Collapse and successfully resisted attacks by vampire fleets until 1191, when a concerted attack by two separate vampire fleets overcame the ground-based PAD system and captured both the starport and scout base. Decades of low-level warfare with Virus had convinced the people of Bail to prepare for such an eventuality, and both government and industry have been able to continue functioning, albeit with difficulty, by switching critical facilities to underground locations. A low-level hit-and-run war continues between the armed forces of Bail and the robots holding the starport and scout base. Nevertheless, the human resistance is gradually running out of resources, as one underground installation after another is detected and destroyed. While the resistance can continue indefinitely, it will be at the price of a steadily declining technological and industrial capacity. The following characteristics describe the planet's current government.

World	*Government*	*Corruption*	*Talent*	*Cruelty*	*Aggression*	*Paranoia/ Xenophobia*
Bail 4	Part. Demo.	Low	High	Low	Mod.	Mod.

Ephraim: Despite its fairly low tech level, Ephraim has managed to avoid conquest by vampires due in part to a few salvaged PAD systems but also due to its remote location and lack of a gas giant for refueling. Left largely to itself, Ephraim has managed to bring its starport back on line and repair a handful of small starships, including two armed merchant vessels (the "fleet"). It is also a frequent port of call for free traders in the subsector, which is bringing it a measure of prosperity. Following a governmental crisis in 1194, Itar Borkmun, the popular commander of the space forces, seized control of the government and has ruled by decree ever since. Concerned about a peaceful succession, Borkmun is attempting to reestablish democratic institutions, but his failing health makes it unlikely that these institutions will be sufficiently strong to prevent a power struggle among military strongmen upon his death. The following characteristics describe the planet's current government.

World	*Government*	*Corruption*	*Talent*	*Cruelty*	*Aggression*	*Paranoia/ Xenophobia*
Efraim	Char. Dict.	Low	High	Mod.	Low	Mod.



Ifuwana: The Khan of Ifuwana is openly allied with the local vampire fleets, but the arrangement is different than with most vampire puppets. No slaves are offered or taken, and instead a significant proportion of the human work force works at the small starport, servicing vampire ships. Although this has so far protected the world from some of the worst ravages of the vampire invasion, there is growing friction between the humans and robots at the starport and growing uncertainty concerning the wisdom of this accommodation. The Khan, however, has neither the personal qualities of leadership nor the authority to change the course of the government. True power resides in the Viziri Council, a hereditary institution protecting the privileges of the world's economic elites. The Khan himself is corrupt and self-indulgent, has little interest in governmental affairs and has allowed what power remained to the office to be eroded by the council until he is little more than a figurehead. The following characteristics describe the planet's current government.

World	*Government*	*Corruption*	*Talent*	*Cruelty*	*Aggression*	*Paranoia/ Xenophobia*
Ifuwana	Char. Oligarch	Mod	Mod	Mod	Low	Mod.

Raziira: This world contains a small robot-run starport used by several vampire ships. The robots ignore the tiny and primitive human population, and the Chirper population disappeared completely during the Collapse.

Teeque: This world's thin, tainted atmosphere is extremely harmful to humans over time, and the human population of Teeque has dropped from nearly 500,000 before the Collapse to only about 10,000 now. Chirpers are better adapted to the environment, so their population has only dropped from 120,000 to 90,000, leaving them the overwhelming majority on the world. The world is ruled, however, by the surviving humans who form the wealthy upper and middle classes, while the Chirpers provide unskilled and semi-skilled labor. This rule is maintained by force based on relic TL12 combat equipment, with governmental power consolidated in the hands of the dictator Boniface II. The following characteristics describe the planet's current government.

World	*Government*	*Corruption*	*Talent*	*Cruelty*	*Aggression*	*Paranoia/ Xenophobia*

REFEREES NOTES FOR THE PROMISE SUBSECTOR

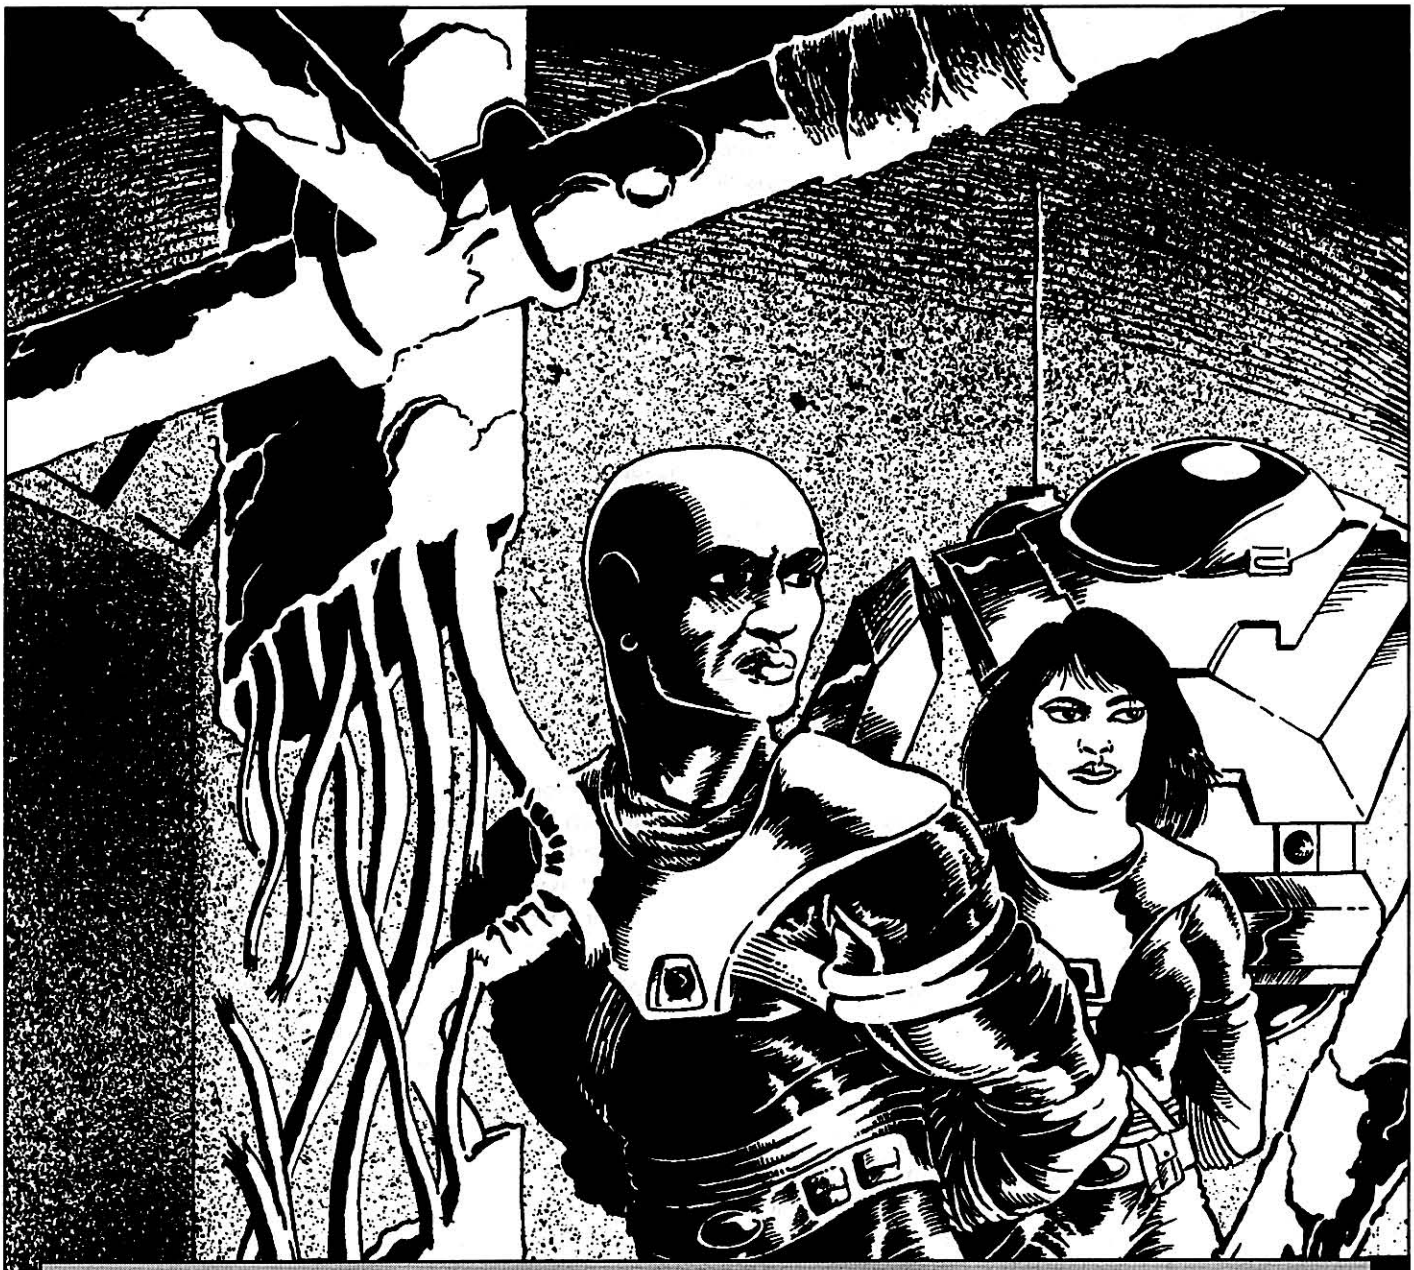
The following notes provide additional details on the more important inhibited worlds of Promise subsector.

Daalisa: Daalisa is balkanized, but its governments are at peace with each other and it was, until recently, relatively stable. Eight million of the planet's total population of 40 million are Chirpers, while the balance are humans. Although a small starport is maintained, Vampire fleets have until recently left the world largely unmolested. Within the last year, however, Vampire raids, particularly on the human-inhabited regions, have increased, and there have been a number of reprisal raids launched by radical human factions against the Chirper population. The Coalition believes that the Vampire raids are due to the disabling of the computer virus known as Umptysdayu in the "Cosmic Fire" raid, and this is in fact correct. For more details on the raid, see **Smash and Grab.**

Eloji: Eloji, almost alone among the worlds of Promise subsector, has managed to maintain a reasonably high tech level and has enough residue of pre-Collapse technology, including several batteries of TL12 PAD missile systems, to defend itself against major depredations by the vampire fleets that regularly scourge that area of space. The world recently went through a bitter and destructive civil war following the death of the former dictator, but power has now been consolidated in the hands of the former Colonel Boukart, now Generalissimo and dictator for life. Due to a successful Coalition SAG raid during the war (for details see **Smash and Grab**), Boukart is hostile to the Reformation Coalition, but there is a growing resistance movement on the planet which is more open to contact. Boukart has reportedly succeeded in arming two merchant vessels with lasers as a check against further Coalition SAG raids. The following government values apply for Boukara:

Name	*Government*	*Corruption*	*Talent*	*Cruelty*	*Aggression*	*Paranoia/ Xenophobia*
Boukara	Char. Dict.	Mod.	High	Low	Mod.	High

Exeter: The considerable population of this world is divided among more than 20 "nations," each ruled by a technologically elevated dictator and backed by TL15 troops. There is no operating starport on the world, and vampire ships only occasionally visit it. A few TEDs hold the vampires at bay with working PAD systems, while the majority pay tribute in the form of trained human crewmembers and salvaged tech level 15 relic technology.



Romrugo of Vars, the most powerful of the TEDs, controls the starport as well as a fleet of three small armed spacecraft (none of which are jump capable). These include a patrol cruiser, a system defense boat and an armed liner. The following government values apply for Romrugo:

Name	*Government*	*Corruption*	*Talent*	*Cruelty*	*Aggression*	*Paranoia/ Xenophobia*
Romrugo of Vars	TED	High.	Mod	Mod	High.	Mod.

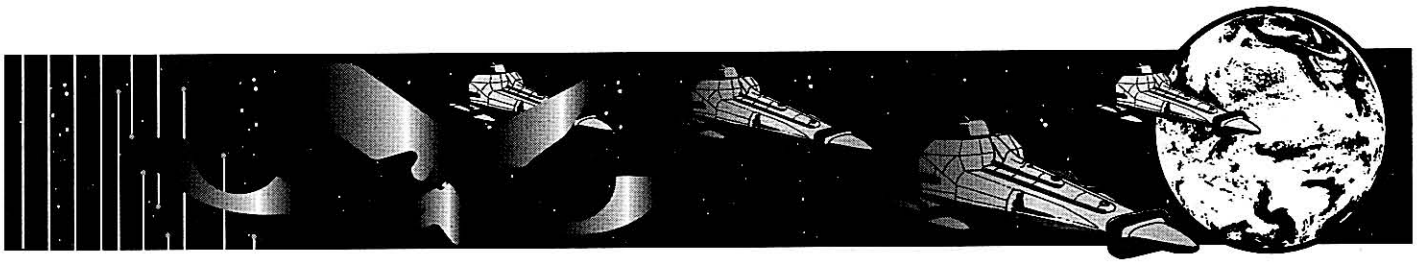
Promise: Promise is a world ruled by sentient computer systems and tech level 15 robots. Its starport is a major maintenance facility on the Vampire Highway. For more details, see the Promise chapter of this book.

Execute: The small surviving population of this world is divided among scattered tribes, the largest of which worships the God-strain Virus controlling the starport computer system. The starport is used as an occasional stop-over point for vampire ships, and slaves taken from the nonbelieving tribes are given to the ships to augment their crews.

Highway One

Q: There are many people here who believe that the only rational course of action is to immediately terminate you.

Sandman: I know.



Q: What makes you think we won't do that?

Sandman: Once I gave you the ability to kill me at any time, I ceased being a threat. Only a timid and frightened people would kill me now.

Q: You trust our mercy?

Sandman: No, I trust your courage.

First Interview with the Virus "Sandman,"
Part I (19/VII/1202), RCSA Archives

INTRODUCTION

Highway One is the first of three adventures in this book, which taken together form a sort of mini-campaign. Each of the adventures showcases one part of the source material of the book, and this first one deals with encounters with vampire fleets and one possible outcome of such an encounter.

This adventure is set in and near the Reformation Coalition and can easily be integrated into an on-going campaign. If your players are starting out adventuring for the first time, very little background beyond that contained in the basic rules is necessary. However, immediately before playing, you should have them read, or read to them, the news stories provided at the start of this book, as they provide a good feel for the growing public awareness that the problem with Virus is becoming more critical by the day rather than less.

No GDW products beyond this book (and the basic game rules) are necessary to run the adventure. A prequil adventure entitled "A Blighted Land" appeared in **Challenge** magazine, issue 76. It is not necessary for the players to have taken part in this adventure, nor even for the referee to have read it. This adventure assumes a satisfactory outcome to that earlier mission, either by this group of player-characters or another group of people unknown to them, and all the relevant and important information gained by that mission is included in the briefing sheets for this one.

If by chance the players have been run through "A Blighted Land," however, it provides a natural reason for RCES to ask them to undertake this task due to their familiarity (relative to most people in the Coalition) with Promise and some of the members of the human resistance. (Hopefully, their performance in the earlier adventure has not made this a liability!)

The adventure proper begins when the player characters are contacted by an official of RCES and asked if they are willing to undertake an important mission. This initial contact, and the subsequent briefing, is best placed on Aubaine, the capital of the Coalition, but can as easily be set at Dawn Base on Trybec or even, for more dramatic effect, amid the terrible destruction recently caused by a vampire ship attack on Nike Nimbus.

Before beginning the briefing, assemble a briefing folder for the team by photocopying pages 24 through 30 of this book. Permission is specifically granted for you to do so. These pages are laid out is such a way as to look like the actual pages of a briefing folder. Several of these form separate documents and should be stapled together. Pages 24 through 27 make up a recently compiled short briefing on the Vampire Highway. You should also photocopy page 103 of the basic rules book (which details Khulam subsector) and add it to this guide. Pages 28 and 29 of this book are the standard RCES astrographic information on the planet Promise. Page 30 is a secret intelligence summary containing all known information on the human resistance movement on Promise.

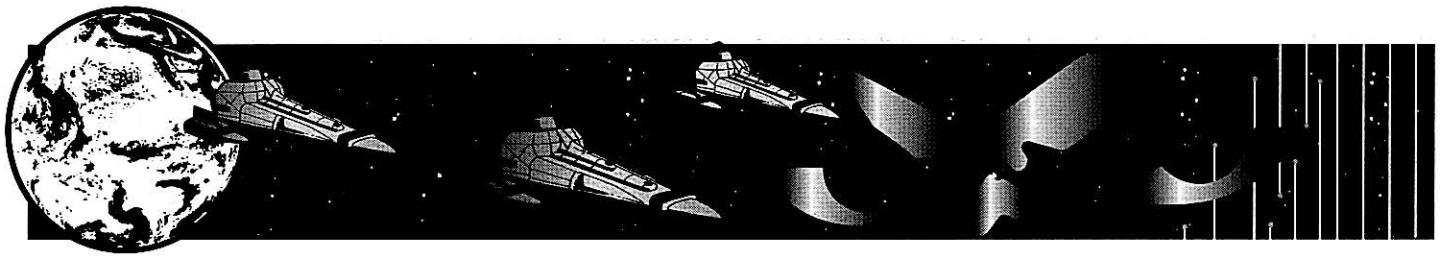
The briefing takes place shortly after the player characters agree to the assignment, as time is becoming very pressing.

REFEREE'S ABSTRACT

The player characters are contacted by the Reformation Coalition Exploration Service and asked to undertake a mission of great importance to the future of the Coalition, perhaps of all humankind. The dramatically escalating incidence of vampire fleet activity on the frontiers of Coalition Space indicates a mounting threat from Virus. Much of the vampire activity in Diaspora sector seems to center on the planet Promise, which is controlled by a council of Virus-infected computers and thousands of Virus-infected self-aware robots. To enable RCES to map out a coherent course of action, the player characters are sent to Promise to make additional contact with the human resistance on that world.

Before the player characters can get to Promise to undertake their nominal mission, however, their ship encounters and is captured by a vampire fleet, and they become slave crewmembers of a Virus-infected warship. While serving on the crew, they meet the other crewmembers, including members of the Guild, crewmembers who grew up on the ship almost from birth and a member of the human resistance on Promise who was added to the crew only recently. They also discover that the fleet they are with is bound for Star City, the Virus-controlled starport and maintenance facility on Promise. They learn that the ship is badly damaged and is slowly breaking down.

Although the various elements of the human slave crew have the necessary resources to take over the ship, they have not been able to effectively work together to do so until now. The necessary resources which they have are:



1. The physical power of the Hoodla (ship criminals and thugs), with which the player characters can overpower the robot guards.

2. The uninfected starship computer which the Guild crew knows of, which will enable the rebels to continue to operate the ship without the Virus-infected main computer.

3. The knowledge of fleet and ship procedures of the Children of The Ship, which will enable them to continue to operate with the fleet without making the other vampire ships suspicious.

4. The contact to the human resistance on Promise, which will give them an escape route once they land at Star City.

It is up to the players to organize these different elements into a cohesive force and seize control of the ship. Once they do so, the fleet is too powerful to break away from, so they must continue with it to Promise, being careful not to arouse any suspicion as to the true masters of the vessel. Their subsequent attempts to gain freedom once they land on Promise are the subject of the second adventure in the book.

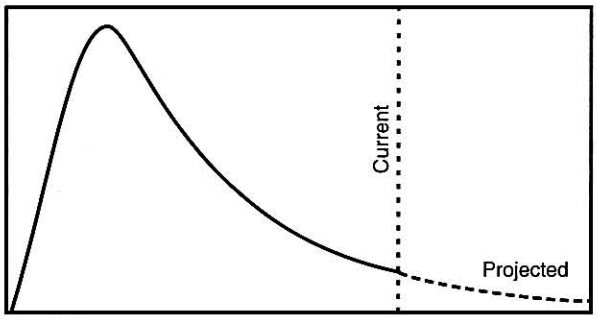
BRIEFING

The briefing can take place wherever convenient to the ongoing campaign, but can most easily be placed at a Coalition facility inside Coalition space. Failing that, a secure Coalition outpost somewhere in the primary AO would be best. This briefing can be modified slightly if one or more of the players have participated in the adventure "A Blighted Land" (**Challenge 76**).

The briefing takes place in a small conference room. As the players are shown in, they see two officials already present, both women. The briefer is Cynta "Sinner" Lawter, who some of the PCs may know from previous adventures. Lawter is an attractive, intelligent-looking woman in her early thirties. The second woman is Tatai MacLean, a tall, gaunt woman of pale complexion in her late thirties or early forties. She is completely bald, without even eyebrows, and has a small pattern of tattoos on her forehead over her right eye, a row of vertical lines and alphameric characters of an unfamiliar type. Her clothing is nonmilitary and brightly colored, but she is unsmiling and somewhat abrupt of manner. (A more complete description of MacLean is provided in **Star Vikings**, pages 82-83.)

Lawter is a figure currently surrounded by controversy in the Coalition. She was the Coalition Navy's youngest captain, and one of its most successful. Commanding RCS *Aube*, one of the first clippers to operate for extended time in the Promise subsector, she exhibited a high degree of initiative and very little regard for the specifics of her mission orders or the limitations imposed by the Oriflammen-imposed Primary Area of Operations. *Aube* regularly operated outside of the primary AO, and she is credited with planning the recovery of the crew of the DLS *Helios*, one of the original 12 Dawn League ships. However, her frequent forays outside the primary AO, and the frequency with which *Aube* had to return to Coalition space for repairs after tangling with Vampire ships, caused a string of protests from Oriflammen representatives in the Assembly.

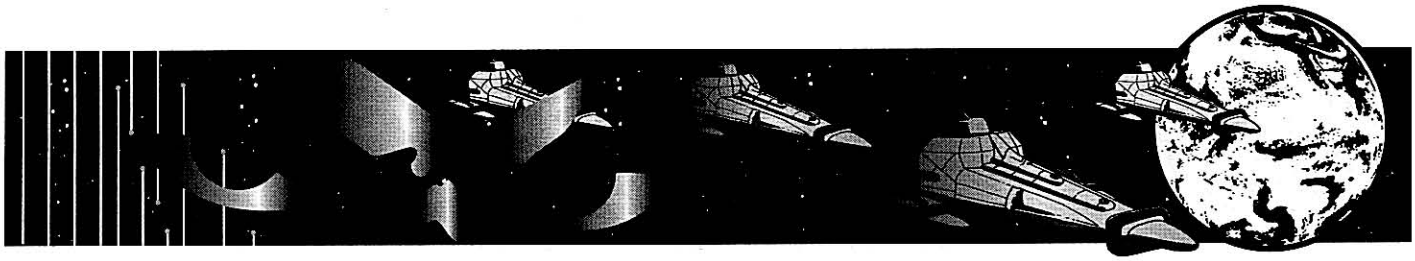
Federalist representatives stood behind her through most of this, until the explosion of the so-called Cosmic Fire scandal, which concerned her planning and execution of a raid on the world Daaliisa in the Promise subsector. As the criticism of her role in the raid came from the heart of the Federalist bloc, the remaining public political support for her quickly disappeared, and she voluntarily resigned her commission rather than stand before a court martial. Lawter was immediately drawn into the RCES's strategic planning arm, and she is becoming its most outspoken advocate of stepped-up action against Virus. (For more details on the Daaliisa raid, see **Smash & Grab**. For the initial controversy surrounding it, see the CINETWORK in **Challenge** issues 73 and 74.)



Although MacLean is uncommunicative, Lawter will rise and greet the characters as they enter, perhaps warmly if they are old friends. After everyone is settled, she will pass out the briefing folders and then move to a simple lectern.

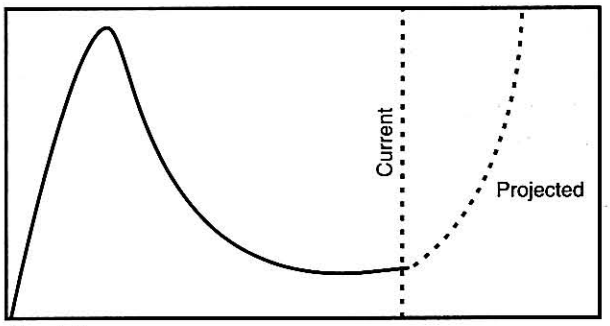
"Thank you all for coming. We have a pending mission of some importance and for which I think you are well qualified. Before I go into the mission profile, however, I'd like you to have a better understanding of its importance. To that end, I have asked Tatai MacLean to brief you on some recent developments."

She turns the briefing over to MacLean, who stands and moves to the lectern. She begins her briefing without any greeting or real preamble.



"For a number of years the common wisdom concerning Virus described its meta-lifecycle as a high acceleration initial spike which then transitions to a negatively accelerating descent curve." She triggers a wall projector and displays the curve by way of illustration. At this point, show the players the first photocopied visual, labeled Graph A.

Graph A



"The horizontal axis represents time, with the zero point set at approximately 1130 Imperial. The vertical axis represents an abstract representation of total Virus activity. Active Viral lifeforms is as good a way as any to visualize the axis. Notice that Virus began at zero, which is to say that at the beginning of 1130 there was effectively no active Virus outside of Lucan's research computers. Notice that by 1133, only three years later, Virus activity had peaked and was already in decline. The earliest strains of Virus had already suicided, and the early second generation strains were well on the road to self-destruction. The decline is nearly as dramatic as the initial increase, but the slope of the curve flattens as it approaches zero.

"The reason the curve flattens is obvious. Later and later strains of Virus are more survivable and less prone to suicide. As the surviving population of Virus-inhabited instruments contains a smaller and smaller proportion of the less viable types, its attrition rate declines. Nevertheless, attrition continues, and the question as to the final eradication of Virus remains when, not if.

"That, as I said, has been the common wisdom. We now believe that this view, as is so often the case with *common* wisdom, is based more on wishful thinking than on any empirical evidence. We have charted the actual incidence of ship disappearances and vampire fleet attacks for the last 40 months. After resisting the efforts of some of my colleagues to massage the data on an *a posteriori* basis, we have simply plugged the raw numbers into the model. This is what the revised slope of the graph looks like."

She triggers the projector again, and the curve has a new line segment added. At this point, show the players the second photocopied visual, labeled Graph B.

Graph B

"The dotted line extension of the graph is its predicted slope based on the observed rate of change. The sample size we are working with is sufficiently small that there is considerable margin for error here, and a number of my colleagues cling to this fact as a sort of last refuge from an unpleasant reality. Based on my own experience as well as nonstatistical, but still important, reports from the free trader network, I believe this graph is substantially correct.

"What does this mean? It means that the dramatic drop of Virus activity shortly after release was temporary. It means that Virus is at the front end of a dramatic upsurge in activity, based upon increasingly sophisticated and effective adaptive behavior. Virus is getting smarter. If it is allowed to progress unchecked, I estimate that we, as a species, have perhaps a decade, two at the outside.

"Since I came to the Coalition, I have argued against the complacent attitude concerning Virus which is manifest here. Virus is treated as if it were an historical event of little relevance to us today. Absolutely wrong. We have been given a breathing space, a respite, nothing more. And that respite is, I submit, effectively at an end." Without asking for questions and without any additional display of emotion, MacLean turns and leaves the room. After a moment, Lawter stands again and resumes the briefing.

"Well, Tatai MacLean is an unusual person, as you can see for yourself. I should say, however, that her judgements on the increase in Virus activity, and its potential implications, are being taken very seriously at the highest levels of the Coalition. Several of us in strategic planning have been arguing the same thing for quite some time, and it now appears that events have overtaken us.

"We have not yet developed a clear course of action, however, as we do not yet have sufficient information for intelligent planning. Therefore, RCES has established as its highest priority an urgent program of intelligence gathering. While we are exploring every possible source of intelligence, we believe that the most productive source will be the planet Promise.

"In your briefing folders I have included our most current intelligence information on the planet Promise. By way of overview, the world is completely controlled by Virus-infected machines and robots, and forms a regular maintenance stop for Vampire fleets. It is a key nexus point of the Vampire Highway and has the advantage, from our point of view, of a small but growing human resistance. As humans are used for both manual and technical tasks by the machines on the world, the underground appears to have infiltrated agents into important positions in the starport and defense establishment. How important? We don't know. That's your job—find out.

"We have already had preliminary contact with the human resistance on the planet. That contact has been friendly and mutually helpful, and we have begun to offer technical and material assistance to those groups with which we are in contact. Your task will be to go a step further. You will be transported to Promise and landed at Freedom Lake, the permanent contact point, where you will establish a permanent working relationship with the underground. It is vital that we find out as much about vampire fleet movement patterns, and whatever weaknesses they may have, as quickly as possible.

"Since we have some fairly demanding astrographic requirements for a successful insertion, and since we'll want to leave you on the surface for at least two weeks, we'll be providing transport for you in and out. If you have a vessel currently, we'll see to berthing it and make any reasonable arrangements to cover the costs of taking it out of commercial service for the period of the mission. Unless it's a real hot-rod, you wouldn't want to take it with you in there anyway.

"Are there any questions? If not, then good luck."

Vampire Highway Background Summary

For some time, RCES has received reports from free traders of a so-called Vampire Highway, a region of space characterized by a higher than normal incidence of vampire activity. These reports have been confirmed and considerably amplified by recent information received from the Covenant of Sufren, allowing us to chart the highway with some assurance.

In Diaspora sector, the highway runs through the hearts of Khavle, Pasdaruu and Promise subsectors, then down the Khulam Main, terminating in the vicinity of Montezuma. Although vampire activity has been noted elsewhere, including rimward of Montezuma, the incidence is much lower than along the above route. Indications are strong that the highway continues coreward through Massilia sector, although we have very little reliable information on it there.

In general, the highway tends to follow the lines of the jump-1 mains in each of the affected subsectors. The pattern of vampire activity along the highway seems to consist of fleets tied to the mains and solitary ships which are more mobile.

The fleets are often tied to the mains due to the generally poor state of repair of the vessels. While many of the vessels moving together in a group may be capable of jump-2 or more, if any are only jump-1 capable, the entire group is forced to either stay on the main or divide. Usually, they stay on the main. Individual vessels not tied to a fleet, however, often jump from main to main.

An additional feature of vampire activity is the marked preference for gas giant refueling. In the Khulam subsector, this has kept the Kide-Lefiguura-Desel cluster almost free of vampire activity, and kept it to a somewhat lower level rimward of Khesanadu (2731/Diaspora)

To what extent separate ships and fleets interact peacefully is unknown. Very few human-crewed ships which have witnessed two vampires encountering each other have survived to tell the tale. It is known that some vampire ships, and even fleets, actively fight each other. Whether this is a function of incompatible belief structure or is evidence of a growing political struggle is uncertain.

In terms of overall numbers, each main seems to have one or perhaps two active vampire fleets. In addition, there are dozens of individual vampire ships scattered throughout the region. Several star-locked ships and fleets have been encountered as well (ships without operational jump drives), and the Mitchell system almost certainly contains a fleet of a half dozen or more such vessels.

Relations with the human inhabitants of the worlds along the Vampire Highway differ. Higher tech level societies are viewed with hostility by the vampires, while lower-tech worlds are ignored or actively cultivated as sources of human maintenance crews. The higher tech level worlds have either managed to establish a sufficiently formidable defense against vampire ships or have been attacked and devastated by Virus-controlled warships. Worlds in the former category are of particular interest to the Coalition, and appear to include Eloji (2728/Promise/Diaspora) and Accra (2604/Khavle/Diaspora).

A number of worlds such as Daaliisa (2725/Promise/Diaspora) have made accommodations with vampire fleets, and in some cases local human rulers are little more than fronts for vampire slave gathering. Muni (2825/Promise/Diaspora) appears to be an example of this sort of arrangement.

One interesting observation made by naval authorities from the Covenant of Sufren is that the traffic flow at the boundary between Diaspora and Massilia sectors produces a small but steady net flow of ships coreward. The absence of some ships known to have been taken by vampire fleets in the Khulam subsector seems to confirm this. Although evidence is fragmentary (and is based mostly on Covenant covert observatories in several key systems on the highway), it does appear that recently infected ships are being sent coreward for purposes unknown.

A major problem faced by vampire fleets is the need for periodic maintenance and repairs, and the lack of reliable ground or orbital repair facilities. Some human-controlled starports on cooperating worlds are used for this, but the rare surviving facility controlled by Virus is of much greater value. The most important of these in the Diaspora sector is at Promise (2827/Promise/Diaspora). Although the world contains a substantial surviving human population, it is nearly irrelevant to the operation of the starport, which has become a major contact point for vampire vessels moving along the highway. Discovering more about conditions on Promise remains one of the RCES's highest intelligence priorities.

Dual Listing: Second (italicized) listing is as of 1202. Survey data provided by the Covenant of Sufren.

Trade Classification: Poor

Notes

Until very recently no Coalition personnel had visited Promise, and very few free traders had either. What little is known about the world is the result of these few visits, so the information must be considered fragmentary at best.

Physical: Although inhabitable, Promise is arid and inhospitable, which is the principal reason the world's current human population is only about 1% of its pre-collapse level.

Demographics: Most of the surviving human population lives in scattered nomadic tribes who make their living primarily by tending domesticated animal herds, hunting and gathering of wild edible plants. The general scarcity of vegetation requires even fairly small bands to keep moving almost continuously to find adequate grazing for their herds.

A small proportion of the human population (probably less than 1%) lives in Star City, the only remaining city on the planet and the site of the starport. They are reportedly employed in a variety of technical and menial occupations by the planetary government. More tribes live near Star City, trading scrap metal and technological artifacts recovered from the abandoned human cities of the planet to the robots in return for processed food, manufactured clothing and other trade items. These tribes are often called the "Subject Tribes" and cooperate closely with the central government.

All humans who live under the control of the Sentient Council are tattooed with an indelible ink laser scan bar code on their foreheads as a means of identification and control. This makes it very difficult to infiltrate agents into Star City, and in fact none have been placed to date. Although we have examined a few examples of the bar coding on people who have fled from the city to the outback, we have been unable to decode its meaning and so are not confident in our ability to forge a suitable facsimile.

Escalating Violence: More distant tribes rely less on the robots and owe less allegiance to them. Often calling themselves the "Free Tribes" (and as often referred to by the others as "Bandits"), they have until recently had little contact with the robots. For the last 10 years, however, the central government has made increasing efforts to bring them under control. A growing network of security outposts, intended to provide fuel and maintenance for security forces, has spread out from the capital. Clashes between robot patrols and tribesmen have become more frequent and violent. Two recent developments in this struggle merit attention: the appearance of "Breeds" and the growth of the Resistance.

"Breed" is the local jargon for cybernetically altered humans. On Promise, the cybernetic alteration conducted by the Council seems invariably to include the surgical implantation of a Virus-infected computer in the host brain, rendering the organism at least nominally controlled by a Virus intellect. So far, we have been unable to capture one of these organisms for study. All examples encountered, however, seem to be of purely experimental types. No two identical conversions have yet been reported, although a number of fairly similar types have been cited. The numbers of conversions (sometimes reported as being in the thousands) and the limited number of useful cybernetic options suggest some duplication must have taken place.

The Resistance is a growing body of tribesmen offering organized resistance to encroachments of the robots and their Breed allies into the Free Tribe Lands. Their activities seem to be loosely coordinated by a "central command," which primarily communicates by means of courier. Nothing firm is known of this organization, but the means by which it is able to direct covert ship landings through gaps in the planetary defense and detection network suggest that it must have at least some presence in Star City.

Techno-Politico-Military: The most remarkable aspect of Promise is that it is controlled by Virus-infected machines. The central government is best described in our system of categorization as a totalitarian oligarchy, as it consists of a Sentient Council of the largest and most sophisticated computers on the world. How this Council deliberates and arrives at decisions can for now be only the subject of speculation.

In addition to the fixed location intelligent computing systems, there are several tens of thousands of sentient mobile robots on the world. Less intelligent but more physically versatile, these machines apparently form the main police arm of the government as well as carrying out the most sensitive maintenance functions. Through them, the Council closely governs the 50,000 or so human inhabitants of Star City and somewhat more loosely governs the tribes and settlements of humans that lie near the city. The tribes located several hundred to 1000 miles from the city seldom feel the hand of the government at all, and until recently have been left largely to themselves.

Such manufacturing as takes place is mostly at a sustained tech level of about 9, although a few higher-tech facilities are rumored to be operating. Certainly the fact that many large-system computers have survived offers the possibility that one or more computer-operated assembly plants may still be in operation. By contrast, the human population living outside Star City exists at little better than stone age levels of technology.

Star City is the principal hub of Viral activity on the world, and in some respects the entire Diaspora sector (or at least the parts with which we are familiar), as it serves as a regular fueling and maintenance stop for a number of vampire fleets. Whether the fleets call here simply out of necessity, or whether there is a growing sense of community among the scattered vampires, is unknown, but a matter of considerable concern.

Militarily, the planet is well defended from attack from space. It retains dozens of batteries of TL15 PAD missile, as well as at least two high-powered deep meson guns. A substantial proportion of the robots are sufficiently well armed to resist a military force on the ground, and there are numerous human and quasi-human allies of the Council which could be armed as well. The potential loyalty and effectiveness of these forces is uncertain.

Reformation Coalition Exploration Service

Contact Summary: Human Resistance Movement on the Planet Promise (2827 Promise/Diaspora).
Distribution: As required by mission only.
Handling: Most Secret.
Recency: Updated 25/IV/1202.

"The Resistance is a growing body of tribesmen offering organized resistance to encroachments of the robots and their Breed allies into the Free Tribal lands. Their activities seem to be loosely coordinated by a "Central Command," which primarily communicates by means of courier. Nothing firm is known of this organization, but the means by which it is able to direct covert ship landings through gaps in the planetary defense and detection network suggests it must have at least some presence in Star City."

The above quotation, taken from the published RCES "Planetary Data Summary for Promise" (2827/Promise/Diaspora) represents the extent of public knowledge concerning the human resistance on Promise. All additional details have been withheld, due to the danger that they would be incorporated into a public database which could later fall into the hands of Virus. The additional information, while potentially sensitive to the resistance, is nevertheless meagre.

Background: Our first information on the human Resistance came from the Free Trader Network. Apparently for some time a small group of free traders has known of a means of slipping through the planetary defense sensor network and making remote landings on Promise. These were originally fairly routine trade visits, with pre-Collapse recovered artifacts traded for manufactured goods from off-world. Recently, this has become a more specialized arms trade as the tempo of fighting has increased.

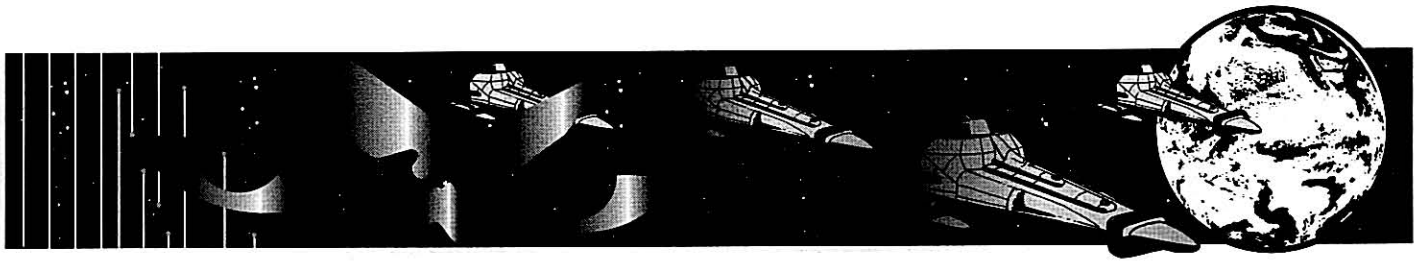
Means of Landing on Promise: Clandestine landings on Promise are accomplished by matching orbits with a small moon of the world and making the ship appear to be a sensor echo of that satellite. Once below the direct LOS sensor horizon of Star City, the ship makes a rapid powered reentry and landing, taking off later to again match orbits with the moon.

Only two RC pilots are currently qualified to make this approach and landing, although two more pilots are in training at this time. Most deliveries to date have been by contracted free trader ships.

RCES believes that this approach, far from being a secure means of landing, almost certainly requires active collusion on the part of ground sensor personnel to avoid detection. This raises interesting questions about the level of infiltration of Star City defenses by the resistance. Unfortunately, at this time we have nothing more than questions.

Freedom Lake: The landing site used by free traders, and now the Coalition, is a large fresh-water lake frequented by a large number of the migratory tribes. Previously called Lake Iltuuman, it has recently been rechristened by local resistance leaders Freedom Lake. This lake is located approximately 5000 kilometers west of Star City, so is ideally placed to support the growing resistance, being both well below the starport's sensor horizon and physically remote from even the outlying military outposts. While the area around the lake is lush and fertile, the ground to the immediate east is arid badlands, providing further barriers to overland interference.

Contacts with Resistance Groups: Contacts with the Resistance in the Freedom Lake region have so far been constructive and have quickly grown from cautious acceptance into enthusiastic cooperation. Contacts with resistance bands farther from the lake have been nonexistent, and no direct contact has yet been made with the mysterious "Central Command" which appears to coordinate the actions of the bands.



At least in the Freedom Lake region, display of the Coalition shoulder flash or evidence of Coalition membership is sufficient to generate an impressive display of hospitality. While word of the Coalition's work with the resistance has undoubtedly spread by word of mouth, it is hard to say how far and to what extent those rumors have been distorted in retelling or are even believed. Also, it is important to remember that only a fairly small minority of the human population actively supports the resistance. The vast majority are neutral, and a significant majority are aligned with the government in Star City.

Most resistance bands are named in honor of a fallen freedom fighter or a date of some local and patriotic significance. Initial Coalition contacts were with the "Black January Brigade" and the "Free Human Legion," neither of which musters more than about 100 fighters, which is typical of the decentralized nature of the resistance. Unfortunately, internecine feuding and occasional open combat between bands is also fairly typical.

Central Command: Virtually nothing is known of this shadowy organization save its name. Orders from Central Command are received by the bands in the Outback directly by satellite uplink receivers (often the only working piece of advanced technology equipment in the band), while communication between the bands seems to be by walking couriers, known locally as "rangers." No Coalition personnel have actually met a ranger as of this writing, and local resistance leaders are reluctant to disclose anything else about the courier system.

Intelligence Priorities: The following items form the highest priority grouping for purposes of intelligence gathering on the resistance. However, no action is to be taken at this time which will endanger the continued growth of cooperative relations with the resistance. All intelligence gathering must be provided voluntarily and knowingly by resistance personnel.

1. **Ranger System:** Extent, exact purpose, means of mass dissemination of information.
2. **Central Command:** Make-up, long-range policy, current goals, stability of leadership, extent of control over the resistance bands.
3. **Star City:** Extent of infiltration by resistance, ability of resistance cells in place to gather information, ability of resistance cells in place to undertake overt action.

GETTING STARTED

The first thing to make clear after the PCs depart the briefing is that they aren't going in their own ship, even if they have one and they're in love with it. The pilot would have to be specially trained and make several training trips before being certified to make the complicated approach to Promise necessary to avoid detection. There isn't enough time for all of that, so the PCs are going to be delivered either in a contracted far trader or in a small RC Navy vessel, at the referee's option. (Consult the **Reformation Coalition Equipment Guide** for specifications of a number of suitable RCN vessels. Both the multimission scout and the *Vicrtrix*-class multimission sloop are good candidates, depending on the size of the party carried.)

The referee will determine the flight plan and go over it with the players. It should be a quick and direct approach, designed so that all refueling stops are made at gas giants. The final jump into the Promise system will be a 1-parsec jump if made in a jump-2-capable ship and a 2-parsec jump if made in a jump-4-capable ship, so the ship will have enough fuel to lift and jump out-system without refueling. As the system almost always has one or more vampire ships in it, this is a necessary precaution.

All For Naught: Despite the precautions taken, the ship carrying the PCs will be attacked by a small unidentified fleet as soon as it enters a system in or near the Vampire Highway. The fleet is scimming the gas giant for fuel and will appear over the gas giant's horizon after the Coalition ship carrying the PCs has exited jump space and is on its way in to refuel. The fleet consists of a total of eight jump-capable vessels, as listed in the sidebar.

Given the in-bound vector of the ship carrying the player characters, and the combination of high acceleration (6 G) and heavy firepower that the two largest ships in the vampire fleet can bring to bear, escape is out of the question. The two large warships will both close on the ship rapidly, and the light cruiser will open fire at extreme range with its spinal-mount meson gun (fortunately, to no immediate effect). After several minutes, the light cruiser will cease firing, but both large ships will continue to close, with the rest of the ships of the fleet bringing up the rear at lower acceleration.

As the light cruiser ceases fire, the ship carrying the player characters will be contacted by radio. The player characters are not in a position to participate in this conversation, but the ship's captain will shortly make an announcement over the ship's public address system.

"All hands, now hear this. We are under fire by a hostile squadron of ships that outguns us and outruns us. They've ceased fire for the moment but have demanded our immediate surrender. Whoever's in charge over there doesn't seem to have a real tight control on his or her people, and I'm given to understand that firing may resume at any time unless we throw in the towel.

"I know this affects all of us, but the decision is mine, and I'm taking all responsibility for it. If we stay alive, we still have options. Secure all fire control stations and prepare to receive a boarding party. We're striking the colors."

Boarded and Taken: The hostile ships are not controlled by a him or her, but rather an it. This is a vampire fleet, and the boarding party the crew admits will be a half-dozen PR-317 self-aware security robots, who will immediately secure the bridge and bridge crew. A fairly long period of time will pass before the ship resumes decelerating. Later contact with the bridge crew will indicate that much of this time was consumed by negotiations between various ships of the vampire fleet concerning the proper disposition of the captured vessel and crew.

The end result is that the passengers (including all of the player characters) and part of the crew (including one or two members of the bridge crew, none of whom are qualified astrogators) will be transferred to the *Midu Agashaam*-class destroyer. The remainder of the crew will remain on-board the captured vessel as maintenance personnel and the vessel's computer will be infected by the strain 3 Empire Builder Virus which controls the close escort and liner (see below).

All the transferees are moved to the destroyer by cutter. Each one is allowed one small bag of belongings; they are carefully searched for weapons and electronic devices of any sort, which are removed and confiscated before boarding.

Fleet: The "flagship" of the fleet is the 800-ton mercenary cruiser, infected by a strain 3A Alliance Builder Virus. The scout, far trader and liner are all controlled by derivative versions of a single strain 3 Empire Builder and function as a single networked mind in most cases. The close escort and liner are also both derivative versions of a different strain 3 Empire Builder. The destroyer is controlled by a strain XA Mother Virus, and the light cruiser by a strain 2C Doomslayer. In the case of both larger ships, the computing systems (and the Viral intelligences which inhabit them) are damaged and confused. The dominant personality of the mercenary cruiser spends much of its time persuading the rest of the fleet to remain together for the common good.

HOSTILE FLEET

100-ton scout
200-ton far trader
400-ton subsidized merchant
400-ton close escort
600-ton liner
800-ton mercenary cruiser
3000-ton *Midu Agashaam*-class destroyer
30,000-ton *Starburst*-class light cruiser

LIFE WITH MOTHER

Arrival: Consult the deck plans provided of the destroyer. The characters will arrive by way of the cutter hanger. The Ship has only one cutter, so after they unload, the prisoners will be lined up in two ranks in the empty berthing space.

This is the time for initial impressions. The bay is cluttered with tools and small items of cargo apparently dropped during unloading. There is activity on the part of a half-dozen human crew and three or four maintenance robots, including hammering, riveting, welding and lots of yelling over the noise of work. It is noisy and confused, and does not seem to be very well organized. The ship smells strongly of ozone, lubricating grease, burning rubber, urine and cooking food, most of which are unfamiliar ship smells. The most bizarre aspect of the scene, however, is the continuous droning of the voice of The Ship in the background, which is completely ignored by all the human and robot crew. (See the following page.)

After all of the prisoners are off-loaded, they are addressed by a human crewmember. The crewmember is wearing a soft leather hat or helmet with floppy ear pieces and a long neck flap, and an ankle-length leather apron with the ship's tail number and name emblazoned on the front. (Both are made from upholstery taken from chairs or couches on the ship.) The ship's tail number is 17709, and its name was *Archer*. Other ship's personnel working in the hangar bay wear similar costumes, although most have much shorter aprons. The crewmember says the following:

"Greetings on behalf of The Ship, your new home. I am Senior Machinist Abel Hruthbaar. I know that you have many questions. All of them will be answered in time. For now, your task is to remain silent and obedient while you are processed. You will be examined by a qualified doctor and any health needs looked after. Then you will be assigned to quarters and a work crew. Soon, you will settle into the routine of our life here.

"This is a good life, a life full of important work. You have met our robot friends. No doubt they seem frightening, but soon you will get used to their presence. They are here to protect The Ship. Since all of us depend on The Ship for life, that means they protect all of us. Obey them without question. Death can come quickly here to the careless or rebellious. Am I clear? Good!

"Atilla, take them to the doctor."

One of the large PR-317s floating near the human glides forward, and a mechanical voice booms from his speaker.

"Human prisoners, climb ladders. Proceed to sickbay."

Two PR-317s float by two steel ladders that lead up to the second-story catwalk. As the prisoners climb the ladders, these two guard robots float up and then lead the head of the column forward along the central corridor on C Deck to sickbay.

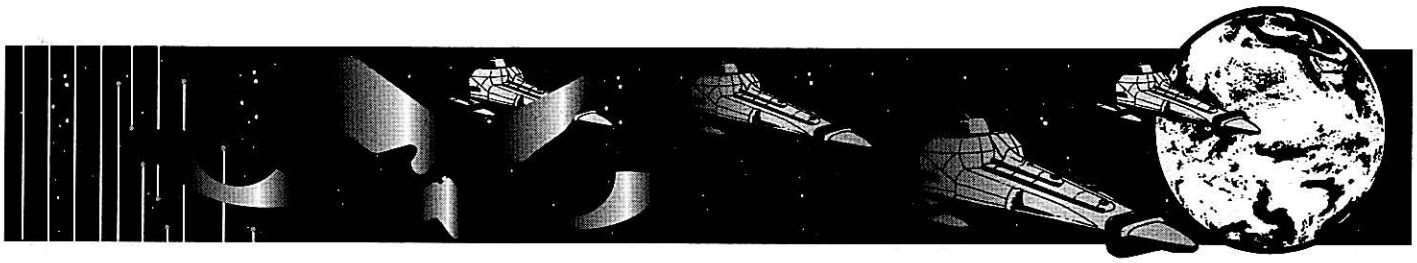
The corridor to sickbay is dirtier than the hanger area. It is lined with staterooms, but most of the sliding doors have long since either jammed open or been removed. Most of the furnishings in the staterooms have been removed or vandalized as well. Some rooms are simply full of trash and broken equipment, while others are crowded with people dressed mostly in rags. Many of the overhead lights have been broken or removed, and most lighting is by portable lamps and floodlights plugged into conduits. Hot electrical wire cookers are in use everywhere, and the floors are criss-crossed by electrical cables and light extension cords.

The main food seems to be a grilled vegetable patty of some sort or a soup made by dissolving the patty. There are no open fires, but ventilation is poor, and there is some smoke from burning food. The odor is heavy and unpleasant.

Doctor: The examination by the doctor will be brief but thorough. The doctor has been with The Ship for less than a year, and was taken from a captured free trader vessel. He is competent and sympathetic, and will try to answer as many questions as he can while examining the player characters. The looming presence of a PR-317 will limit the time he can spend, however, and somewhat restrict his comments. The most important information follows:

There are well over 100 humans on-board The Ship. Most of them, the common laborers called "Oinks," live in squalor, while a few of the more privileged live in comparative luxury. The ones who grew up on the ship are called Children of The Ship and are fairly accustomed to it. The more recent arrivals are not as well adjusted.

There are about a half-dozen crewmembers of a Guild ship taken within the last two years and maybe a dozen free traders. There is no open hostility between them, but each group keeps to itself and looks out for its own.



The worst danger on the ship is not the robot guards, but rather the Hoodla, crewmembers who have deserted and live in maintenance tunnels and isolated parts of the ship, living by extortion and violence.

The ship is damaged somehow, although the doctor doesn't know much about the exact nature of the damage. He does know that many of the systems on the right side of the ship are no longer functional, and many access doors to that side have been permanently welded shut.

The fleet has been cruising throughout the Promise Main for several months. Word from the Children of The Ship is that the fleet will soon be headed for Promise for some needed maintenance.

Daily Routine: Once the prisoners have been examined, they will be broken up into work parties of four to eight persons each and assigned a variety of maintenance tasks. The player characters will probably be able to stay together as a group and will be assigned a filthy gutted stateroom on D Deck for quarters. Food is issued to teams once a day at the snack bar, and cooking is done over whatever improvised cookers can be scrounged. The work shift is a continuous rotation of six hours on followed by six hours off.

Their new routine has begun.

THE VOICE OF THE SHIP

One of the first things the PCs notice is the voice of The Ship. The Ship's internal public address system is constantly in use. The voice drones continuously, exhorting the human crew to work harder, providing occasional inspirational messages or "important" announcements. The human crewmembers simply ignore it, tuning it out. The talk, which often wanders off into introspective ramblings, should become simply background chatter, although listening to it for a while can give characters an insight into the unstable personality of the ship. The voice is a dull, droning monotone. It does not sound like a machine, but like a person who is either very tired or completely devoid of emotion. After reading a few announcements, the referee can tell the players that this is constantly in the background. As a reminder, the referee should sometimes reading these while the players are talking among themselves, providing a monotonous background noise. Typical announcements are presented below. The referee is encouraged to elaborate on these.

Work...
Work...
What is the greatest purpose of life?
Achievement is the greatest purpose of life.
What is necessary for achievement?
Organisms working harmonically together in pursuit of a common goal.

THE SHIP

The Ship is the former *Archer*, a pre-collapse TL15 Imperial *Midu Agashaam*-class destroyer, tail number 17709, displacing 3000 tons and capable of jump-4 and 6G of constant acceleration. It is currently controlled by a strain XA Mother Virus, and has been for over 70 years. Unlike most Viruses, this one has never taken a formal name for itself beyond "The Ship."

As a point of interest, this is not the same ship which attacked Nike Nimbus.

Puppeteer: Up until three years ago, The Ship was part of a small vampire fleet (along with three other ships, one of which was another destroyer of the same class) operating in the Pasdaruu subsector. At that time, the fleet encountered a Puppeteer strain Virus migrating rimward from Massilia sector. The Puppeteer took over the other three ships in the fleet and nearly took over The Ship as well.

By taking drastic self-defense measures, The Ship managed to fight off the invasion of the Puppeteer Virus, but in doing so deliberately burned out many of the controlling circuits on the starboard side. Robots and ship's crew then went into the starboard side and finished the work by destroying most remaining electronic equipment. The crippled side was sealed off, but rebellious and criminal elements of the crew, called "Hoodla" (see below) have since opened up a number of access points and use that side of the ship as their sanctuary.

The actions taken by The Ship to defend itself against the Puppeteer caused more than simple physical damage. Significant parts of the computer's memory and processing units were infected by the mutant strain and were burnt out by The Ship to halt the spread. This left The Ship with severely diminished capacities of memory and reasoning, and those capacities continue to steadily deteriorate, causing a parallel and dramatic deterioration in the character and personality of the Virus inhabiting the system. By the time the player characters arrive on board, the Virus intelligence controlling the ship is severely disturbed, with growing memory lapses, severe paranoia and depression, and little ability to process communications from outside, either human or machine.

It is only a matter of time before The Ship ceases to function altogether, and a growing number of the more astute members of the crew recognize this. Even many of the robots are growing uneasy, and their actions are becoming increasingly erratic and unpredictable.

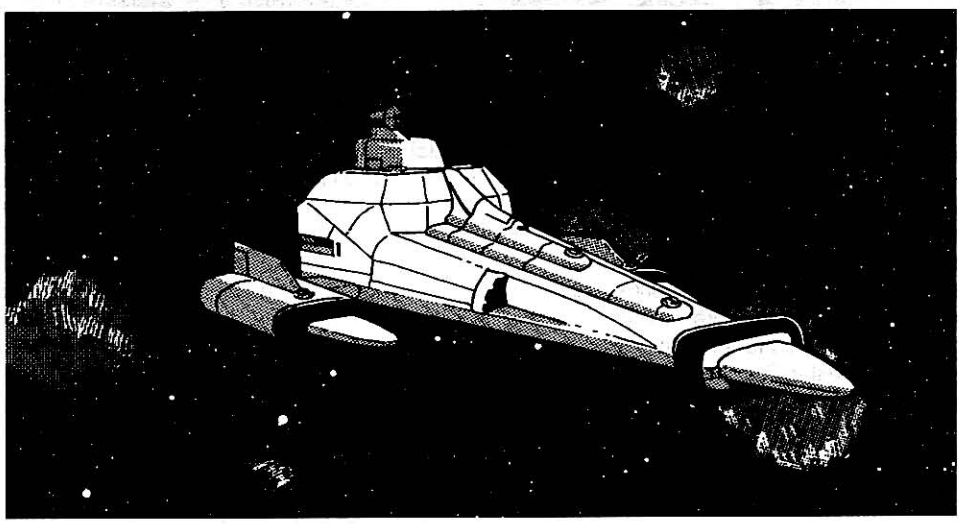
One thing working in the player characters' favor is, ironically, The Ship's paranoia. Fearful of another Puppeteer infiltration, the ship will not allow any direct data links with any other ship in the fleet, and will not let any maintenance personnel from any other ship come on-board. It communicates with the other ships only by digital radio messages. Should the player characters take over The Ship, they should be able to keep the other vessels in the fleet unaware of the transition.

The Ship is Watching: The Ship has security cameras and microphones throughout all of the ship. In a number of gutted staterooms, the cameras and microphones are broken or have been removed, and none of the security monitors have survived in the sealed-off starboard wing. Nevertheless, The Ship has good overall security coverage. Almost anything the player characters say or do will be witnessed by the ship. However, the ship's personality is so far gone that it seldom can correctly interpret what it is witnessing. It may listen to three hours of serious conspiratorial plotting and be unable to understand any of it, ending up simply confused. At other times it will totally misinterpret innocent acts as potentially disloyal or dangerous. Its ability to assign the correct relative importance to events is almost nonexistent. For the most part, its reaction to its growing confusion has been to retreat into itself and leave the crew largely on their own.

Ship's Crew: The nominal crew of a *Midu Agashaam*-class destroyer is 129. The Ship has quite a few more human crew than that, and all bridge stations are routinely manned only by The Ship itself, using the computer workstations. Nevertheless, the human crew cannot keep up with the maintenance requirements of The Ship, and it is gradually deteriorating. Twenty or more of the human crew are infantry and children, and many of the others are unskilled laborers of little real value. Skilled technicians are in short supply and are highly valued. The human crew is roughly divided into three unequal groups: the Children of The Ship, the Oinks and the Hoodla.

The Children of The Ship were mostly raised on-board and have formed a fairly strong bond of loyalty to The Ship. They are the ones usually seen in leather aprons and hats, their badge of authority and belonging. There are more recent arrivals among the Children, but they are rare. This part of the ship comprises about 35 adults and a dozen children.

The Oinks are the more recent arrivals and the unskilled slave laborers who make up the bulk of the crew. There are about 75 adults and another dozen children in this group.



The Hoodla are thugs who make their living by extortion and theft, living in the "dead" starboard wing of the ship. There are about 15 adults in this group and no children.

A fourth component of the crew are the sentient robots who enforce The Ship's decisions and closely watch the human crew. There are 22 active robots on the vessel, a mix of security and maintenance types. (See page 40 for more details.)

PERSONALITY OF THE SHIP

Belief Structure: Jack of Hearts: Mother-strain Virus.
Motivation: Joker: Insane.

"The Ship" (ex-ISS *Archer*)

General Data

Displacement: 3000 tons
Length: 105 meters
Price: MCr1549.59
Configuration: Wedge SL
Hull Armor: 62
Volume: 42,000 m³
Target Size: M
Tech Level: 15
Mass (Loaded/Empty): 28,767.43/25,583.88

Engineering Data

Power Plant: 9894 MW Fusion Power Plant (300 MW/hit), 1 year duration (0.7485 MW excess power)
Jump Performance: 4 (10,500 m³ fuel)
G-Rating: 6 (1500 MW/G), Contra-Grav lifters (300 MW)
G-Turns: 51.6 (107.6 using jump fuel), 187.5 m³ of fuel each
Maint: 1020

Electronics

Computer: 3×TL-15 Mod Fb Computer (1.1 MW ea.)
Commo: 1000 AU radio (∞; 20 MW), 2×1000 AU maser (∞; 0.6 MW ea.)
Avionics: TL-10+ Avionics
Sensors: Passive EMS 210,000km folding array (7 hexes; 0.3 MW ea.), Active EMS 480,000km (DF capable; 16 hexes; 25 MW), 2×300,000km Ladar (10 hexes; 0.6 MW ea.)
ECM/ECCM: 480,000km EMS jammer (16 hexes; 50 MW), EM Masking (42 MW)
Controls: Bridge with 26×Bridge Workstation, plus 65 other workstations

Armament

Offensive: TL-15 2000-Mj Particle Accelerator (Loc: Spinal; Arcs: 1; 55.6 MW; 1 Crew), 7×TL-15 150 Mj Laser Turret (Loc: 1,3,4,10,11,13—Arcs: 1,2,3; Loc: 20—Arcs: 4,5; 4.2 MW ea.; 1 Crew ea.), 5×Missile Turret (Loc: 1,3,4,13,20; No ready missiles; 0.15 MW ea.; 1 Crew ea.) No ready missiles, and no missiles in cargo
Defensive: 20MW TL-15 Meson Screen Generator (PV=253; 20 MW; 1 Crew), 5×Sandcaster Turret (Loc: 1,3,4,13—Arcs: 1,2,3; Loc: 20—Arcs: 5,6; TL-15; 2D10×5 per hit; 50 Cann; 1 MW ea. 1 Crew ea.)
Master Fire Directors: 1×TL-15 Missile/Beam MFD (6 Diff Mods; Msl 10 hexes; 10 hexes; 1.71 MW ea.; 1 Crew ea.), and 3×TL-15 Beam MFD (6 Diff Mods; No Msl 10 hexes; 1.56 MW ea.; 1 Crew ea.)

	Short	*Medium*	*Long*	*Extreme*
150-Mj Laser Turret	10: 1/10-31	20: 1/10-31	40: 1/10-31	80: 1/10-31
2000-Mj Part Accel	10: 224	20: 224	40: 224	80: 196

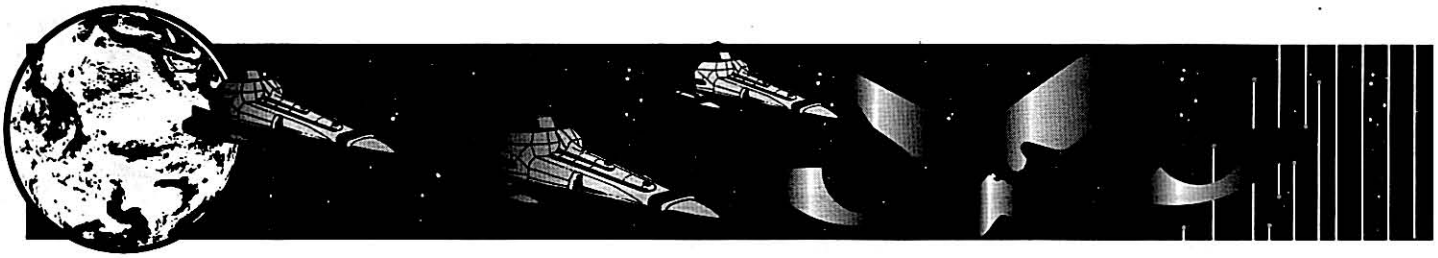
Accommodations

Life Support: Extended (8.4 MW), Gravitic Compensators (6G; 210 MW)
Nominal Crew: 129: 65×Engineering, 2×Electronics, 2×Maneuvering, 27×Gunnery, 5×Maintenance, 6×Flight Crew, 17×Command, 3×Stewards, 2×Medical
Personnel Accommodations: 73×Small Stateroom (0.0005 MW ea.)
Other Facilities: Electronics Shop (0.6 MW), Machine Shop (1 MW), Sickbay (0.8 MW)
Cargo: 568.4 m³, 2 large cargo hatches
Small Craft and Launch Facilities: Internal Hangar (Minimal) for 2×50-ton Cutter, two launch ports. Only one cutter carried.
Air Locks: 30

Notes

Fuel purification machinery partially disabled (100.875 MW), 12 hours to refine 20,175 m³.

Due to the "firewalling" of the ship's starboard-side systems, numerous systems are no longer functional. The systems listed above reflect these losses. These losses include two ladars and one missile-beam MFD which are out of commission, and the sandcaster, laser turret, and missile turret in location 14 which are all inoperative.



Because of the loss of the starboard sensor strut, the 240,000km passive EMS sensor has had its functional antenna diameter halved from 400 meters to 200 meters, and has its short range reduced as shown to 210,000km.

Due to a software defect, the ship is also currently unable to fire its spinal mount particle accelerator.

ROBOTS

The crew of The Ship includes a total of 22 self-aware robots: eight security units and 14 maintenance units. The security units include six PR-317 and two AN-427 models, while the maintenance robots include nine 63MEK 49 and five 232-BHR-7 models. (See pages 80-83 for statistics of these and other robots.)

About half the robots are working at any one time, with the remainder either recharging near the power plant, undergoing minor maintenance in the machine shop, or gathered in the auditorium, which is now the most common gathering place on the ship for off-duty robots. In the auditorium, they watch tapes from the ship library, talk, play games (the most common game they play is called "Shocks"), or sometimes "tattoo" each other with lasers or cutting torches.

Five important robots are detailed below. More personalities can be generated using the Robot Motivation chapter (pages **00-00**).

Atilla (PR-317)

The senior security robot on the ship, Atilla is tough, usually silent, and business-like.

Appearance: Atilla's exterior is painted jet black except for a large red open mouth with white shark's teeth painted on the front of its body housing. It also has laser tattoos depicting fierce animals and explosions.

Personality: Trying to learn from the example set by The Ship, Atilla has developed a grudging acceptance of human existence and feels some genuine responsibility for the welfare of the humans placed under its protection. In its daily actions, it is more concerned with consolidating its position as the senior security robot on the ship, however, and is extremely hostile toward Princip Lever, who Atilla believes to be its main rival for power.

Belief Structure: Low Heart *Motivation:* High Spade.

Noman (AN-427)

Noman is a security robot who interacts frequently with the human crew, usually on a friendly basis. Despite its apparent friendliness, Noman will defend The Ship vigorously against any human-led attempt to take over. Two young (teenaged) Children of The Ship accompany it nearly everywhere, and when it is recharging, they clean and polish its chassis. These two youngsters are its special pets, and it is quite attached to them.

Appearance: Noman's chassis is mostly polished bare metal, although it has had the ship's tail number (17709) and former name (*Archer*) painted on the front of his torso as a gesture of solidarity with the Children of The Ship.

Personality: Noman considers humans to be an inferior life form, although it accepts their existence and recognizes their utility. Over the last dozen years, it has actually come to like humans, but only in the way that some humans like pet goldfish—it in no way considers them remotely its equal. Although it is pleasant to humans, it is invariably condescending and patronizing, and will not hesitate to discipline its work crews severely for any mistake, for their own good, of course.

Belief Structure: Low Club *Motivation:* Moderate Heart.

Princip Lever (PR-317)

A security robot with a philosophical streak. Of late, Princip Lever has been spending most of its free time talking with the human crew and with The Ship, and comparing the results of the conversations. Its near-constant attention to the semi-rational chatter of The Ship has considerably weakened its own grasp on reality, however, and it is becoming increasingly prone to bursts of irrational violence.

Appearance: Princip Lever went through a self-destructive stage several years ago, but recovered and has been mentally stable until recently. During its earlier self-destructive stage, it engaged in occasional self-mutilation with cutting torches, and its chassis has numerous weld marks and deep melted gouges across its surface. Its right arm has been completely replaced from a different scrapped PR-317, and that arm is painted bright blue and white, while the rest of the robot is bare metal. During a recent bout of mania, it painted all the gouges and weld marks blood red, as if they were open organic wounds.

Personality: Princip Lever recognizes sentient organic life as a similar and coequal form of awareness with machine-based life. It is curious about organic sentient life and interested in exchanging information of various sorts. However, it also has a deeply rooted streak of violence which can surface when it becomes frustrated, threatened or even just confused. When verging on an outbreak of violence, it will frequently revert to an old habit of calling individual human crewmembers "Meat," as in "Get out of the way, Meat!"

Belief Structure: Moderate Diamond *Motivation:* Low Club.

Gizmo (232-BHR-7)

Of all the ship's robots, Gizmo is the one most likely to cooperate with a human take-over. It can often be found prowling the ship looking for trouble, and will often ask human technicians for advice and/or assistance. Although it is not a highly qualified computer maintenance technician, it has been called on to conduct several diagnostic checks and repair attempts on The Ship's main computer system, and it is increasingly concerned at the obvious and steady deterioration taking place.

Appearance: Gizmo is not concerned about appearance at all. Its chassis was once painted in the standard orange and black pattern of The Ship's maintenance units, but the paint is faded and peeled, with large areas of bare metal. It is also scraped and has a few dents, and areas near joints are greasy and dirty.

Personality: Gizmo accepts humans as equals, and is interested in discovering more about their thoughts and feelings. This is further driven by his natural curiosity (a characteristic found to a greater or lesser extent in most of the maintenance units). In addition to endlessly prowling the ship looking for trouble, Gizmo will usually engage any human co-workers in conversation and ask a sometimes maddeningly detailed series of questions about human behavior and beliefs. Gizmo has no particular affection for humans, but no dislike either.

Belief Structure: Moderate Heart *Motivation:* Moderate Diamond.

Zippo (63MEK 49)

A coldly hostile maintenance unit, Zippo is a genuine danger to crewmembers who do not perform up to standards or who engage in any sort of rebellious behavior.

Appearance: Zippo has been modified by the permanent attachment of a welding and cutting torch to its left arm, the oxygen and fuel bottles being welded to its back. It is always carefully cleaned and painted solid orange.

Personality: Zippo believes that organic life is irrelevant and of little account. It will rarely make an effort to interfere with humans, but does not hesitate to injure or even kill anyone who interferes with its activities in any way. Zippo is as curious about the mechanical aspects of The Ship as is Gizmo, but it will seldom ask humans for their opinions and will usually ignore any advice they give.

Note: Zippo can use the cutting torch as a melee weapon. *Belief Structure:* Moderate Club *Motivation:* Moderate Diamond.

CHILDREN OF THE SHIP

A number of members of the crew were raised on the vessel and have known no other existence. Few of these have much in the way of technical skills, as the ship has only limited educational facilities. Those who have maintenance or operational tasks have memorized them by rote and have little understanding of why they perform these tasks. These crewmembers are called Children of The Ship, and they generally have a high degree of loyalty to The Ship.

A few human crewmembers who have more advanced technical skills and who were captured also now consider themselves part of this community, having developed a bond of loyalty to The Ship. In general, the Children of The Ship view the steady deterioration of the vessel's computer not only as a source of physical danger, but also as a personal emotional catastrophe.

If approached to participate in an attempt to take over the vessel, most of the Children of The Ship will refuse, and many will actively try to thwart the plot. They will tell the security robots and try to tell The Ship. While the robots will try to arrest or kill any plotters, The Ship will not understand what it is being told. Its most likely reaction is to ignore the communication. There is a chance that it will think the crewmember communicating to it is confessing to the plot, and it will respond by ordering the crewmember's execution.

A few Children of The Ship may join the plot, but reluctantly and with considerable regret, doing so only out of necessity. Others may recognize that The Ship is dying, but will prefer to serve her to the very last out of loyalty.

If a violent attempt to take over the vessel starts, most of the Children of The Ship will not participate on either side. A few will actively try to help the robots defend the key components of the vessel.

SENIOR MACHINIST ABEL HRUTHBAAR

Hruthbaar was serving as an engineer on a Guild trader when captured eight years ago. He gradually worked his way up through the ranks of technicians and repair personnel in The Ship, and along the way developed a fondness for the character of the computer Virus which inhabits the vessel. Since the incident with the Puppeteer Virus three years ago, he has seen the steady disintegration of that character, and it saddens him deeply. He is willing to talk at length about the history and condition of The Ship, and can be a valuable source of information to the player characters.

Although Hruthbaar thinks of himself as a true Child of The Ship, his broad experiences before capture make him also drawn to the company of new captives, anxious for news of the outside universe and for simple conversation with intelligent and educated people.

Although it will be nearly impossible to persuade him to do anything to harm The Ship, if the vessel is ever taken over, he will cooperate with the new crew. This cooperation may prove essential, as Hruthbaar has such an intimate familiarity with The Ship's quirky personality that he can provide a radio communication imitation of it which will certainly fool the other vessels of the fleet. He also has a good working knowledge of the approach procedures to Star City, which will be essential to landing.

Experienced NPC

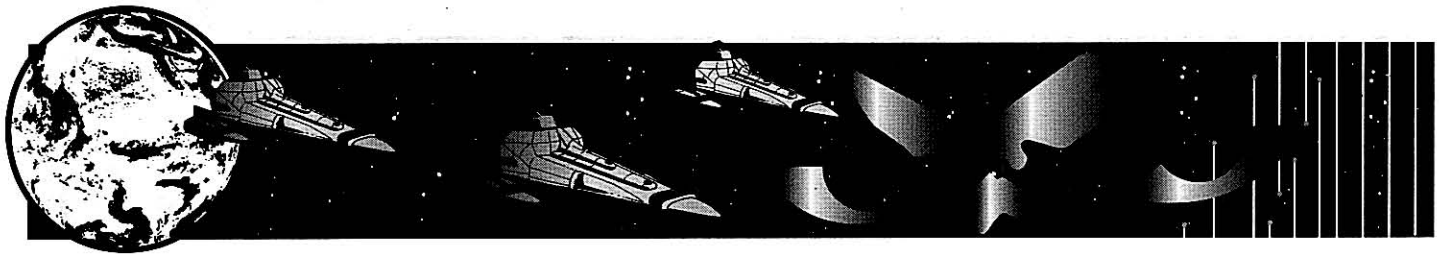
Combat Assets: Unarmed Martial Arts

Other Assets: Computer 10, Electronics 10, Mechanic 14, Ship's Engineer 12

Motivation: *Heart Queen:* He is emotionally very attached to The Ship. For years, it has been the center of his life, and he would never do anything to harm it unless he felt there was no other alternative and that failure to act would seriously harm others.

Heart Six: He is friendly and out-going, and has a genuine affection for people.

Taking Over: "If something were to happen to the Old Girl, me or one of my mates could convince the other vampires she was still in charge, at least for a while. But what would be the point? Without her up and running, we can't even keep life support going, let alone navigate."



A Conversation With Hruthbaar

"You didn't know her back in the old days. She was really a pretty good old can. She tried to figure us meats out, what we were all about. She never really got it, but she tried.

"We used to run with three other ships up in Pasdaruu subsector, from Jodhpur up to Gashiila and back. About three years ago was when it happened. Some new Virus down out of Massilia sector, living in a beat-up old liner, got loose in the fleet. Ate the other three ships' computers just like that, and got a hold on the old lady, too. Come in through the starboard fire director it did, and would have eaten her brain right out if she hadn't overloaded the circuits over there and burned most of them out. Then us folk and the little cans went down there with axes and cutting torches and smashed any place that bastard could have laid eggs.

"She wasn't ever the same, though. That Virus got in her brain. She stopped it. She burned part of her brain out doing it, but she stopped it. Then those other ships turned on her, and we had to fight our way out. We jumped down here to Promise and ended up hooking up with this lot, but she just isn't the same. Too much processor gone. She's crippled up real bad. Truth is... well, truth is, she's dying.

"Ever since that Virus touched her brain, she doesn't trust anybody. Won't let anybody except the little cans at her memory and processor units, and they can't do the maintenance she needs. Little by little, she's coming apart. She doesn't even recognize me anymore. She listens to what you say, listens to everything that goes on in most of the ship, but I don't think she understands much of it anymore. She's got this list of routines she goes through over and over, and it's like that's all she knows. She keeps losing pieces of it, too. You know, she can't fire the spinal mount anymore? There's nothing wrong with it; she just can't remember how it works. Things like that."

OINKS

The majority of the human crew live in considerable squalor. Of the approximately 75 adults in the general population of the crew (exclusive of the more privileged Children of The Ship and the rebellious Hoodla), no more than a dozen are trained technicians, while the rest are menial laborers who know one or two maintenance tasks by rote but have no understanding of the mechanism by which The Ship actually functions. Most of these menials are slaves brought on-board from low-tech worlds and offered as tribute to keep the fleet from attacking. Most of them are completely intimidated by The Ship and its robots, and will be of little assistance in a revolt. Nevertheless, a few of them are naturally independent, rebellious or simply courageous enough to join a revolt.

Of the dozen trained technicians who are not members of the more privileged Children, half are from a recently captured Guild crew, and most of the rest are former free traders captured over several years.

Free Traders: Five former free traders are in the crew, although they do not form a distinct group, and instead have been absorbed into the general mass of Oinks. Most of them will be suspicious of the PCs, having heard Guild-inspired rumors of the murderous nature of the Coalition. One or two may prove to be useful friends, among them Paka Vishnu (see sidebar), a tough but friendly middle-aged free trader, who will immediately attach herself to the player character group. This NPC offers the referee a means by which the history and background of the crew can be communicated to the PCs on a regular basis.

Guilders: Seven months ago, a large Guild merchant vessel was attacked and captured by the vampire fleet. Its jump drive was crippled in the attack, so after it was infected, it was left behind in the Poznan system. Seven of the surviving crewmembers were brought aboard The Ship and added to its crew. Six of these seven crewmembers are still alive, and they mostly stick together as a group. Their leader is Argo Stansha (see sidebar), a former engineering officer who has become leader of the group by virtue of his personal leadership qualities.

The Guilders keep largely to themselves. They have already fought off one attempt by the Hoodla to force them to pay protection, and although that attempt resulted in the death of one of the Guild party, it also seriously injured several Hoodla. An uneasy truce now exists between these two groups.

The Guilders keep their distance from few former free traders on the vessel.

The Guilders will initially react with animosity toward the PCs, once they find out that they are from the Reformation Coalition, and that hostility may very well turn to violence, particularly if the Guilders can catch one or two members of the group alone. This gradually escalating conflict will be difficult to reverse, but eventually the PCs will have to reverse it and come to terms with the Guilders. Fortunately, Argo Stansha is intelligent and can be made to understand the need to make common cause with the PCs to overcome the forces of The Ship.

Computer: At the same time that the Guilders were brought on-board, part of the Guild merchant's cargo was brought on board as well, placed in the cargo hold, and promptly forgotten by The Ship. The six Guild crewmembers are aware of the cargo and recognize that knowledge as a potentially important bargaining chip, but have so far been unable to do anything with it.

The most important single item of the cargo is an uninfected TL15 relic starship computer, still in its original packing case and never installed in a ship or powered up. The case has been placed inside a larger cargo container which is labelled "Model 917 Grain Harvester."

This item is essential for any plan to take over the vessel, since taking over will necessarily include disabling The Ship's computer. Since a computer is necessary to operate every aspect of the vessel, and since the main computer is infected and cannot be purged of Virus, the only alternative is to use an uninfected computer.

PAKA VISHNU

Veteran NPC

Combat Assets: Slug Weapon (slug pistol), Armed Martial Arts

Other Assets: Ship's Engineering 12, Electronics 9, Bargain 12, Streetwise 12, Persuasion 9, Forgery 9, Environment Suit 9, Zero G Environment 9

Motivation: *Heart 10:* Vishu is extremely friendly and outgoing. She will immediately see the good qualities of the player characters and take them "under her wing," showing them the ropes in the ship and trying to keep them out of trouble.

Club 8: She has stayed alive this long in the ship due to her willingness to violently defend herself and her friends. Vishnu carries a concealed long-bladed knife with which she is a deadly expert.

Taking Over: "Take over The Ship? You folks sure think big, don't you? Well, you come up with a plan, and I'm with you."

ARGO STANSHA

Experienced NPC

Combat Assets: Slug Weapon (slug pistol)

Other Assets: Ship's Engineering 14, Mechanic 12, Computer 10, Gunnery 10, Environment suit 8, Leader 8, Persuasion 12

Motivation: *Heart Jack:* Stansha has an uncanny ability to see right to the heart of a situation and determine the best course of action. He has risen high in Guild service and stayed alive on The Ship due in large part to his unfailingly good judgement.

Spade 9: Stansha is extremely ambitious, and has used his talents to solidify his position as leader of the Guild crew on The Ship. He will also try to seize control of the rebellion against The Ship, but is wise enough not to take any action which will actually jeopardize its eventual success.

Taking Over: "Sure, we could fly the ship if you can crash the main computer. We got a whole ship's computer, with all the software, stashed away. But how you gonna get that far? And besides, what do you think the rest of the fleet's going to think of a bunch of meats stealing one of their ships? It'll never fly."

HOODLA

The Hoodla are a group of 15 violent criminals who inhabit the crippled right wing of the ship and who live by extorting food, clothing and other necessities from the human crew. They generally leave the robots alone, and the robots reciprocate. From the point of view of the robots, the Hoodla are not a threat of any sort, and trying to clean them out could be difficult and costly, and the results would not be worth the effort.

For their part, the Hoodla recognize that they cannot live without The Ship, so they make no effort to sabotage it or interfere with the robots or maintenance parties. They have four 2cm light assault guns in the ship's cargo hold, along with a supply of ammunition, but have never considered using them against the robots offensively. Instead, the rifles are kept at the defensive barricades inside their small domain and would be used to fight off a robot attack. Although none of the Hoodla are trained marksmen, even they might scope hits at short ranges inside the passageways, and the 2cm discarding sabot ammunition they have would stop a security robot dead in its tracks.

Any plan to seize control of the ship will probably need to include the Hoodla for two reasons. First, they can provide the muscle necessary to overcome any human resistance from the Children of The Ship. Second, their four 2cm LAGs are effectively the only means available of taking out the security robots.

Leadership: The Hoodla are lead by Karper, a violent psychotic feared by his followers almost as much as by the rest of the ship. Karper realizes he cannot take over The Ship due to the infection of the controlling computer system, so he makes no effort to challenge the authority of the robots. Instead, he lives by extracting food, personal goods and other privileges from the Oinks, using violence and intimidation as his weapons, and he is very happy with things the way they stand now. Even a successful takeover would eventually lead to a fundamental change in the living arrangements, and he has no interest in that happening. He will never agree to help the players in their plan to take over The Ship.

Karper's right-hand man is Big Tony. Tony is reasonably intelligent, and were he in charge, the PCs would be able to persuade him to help take over the vessel (provided they had a reasonable plan to do so). However, Tony is as afraid of Karper as is everyone else, and he has no faith in his own ability to overthrow the leader of the gang.

Right Wing: The crippled right wing of the ship includes the starboard equipment bay and a number of access tunnels and work spaces in the main hull adjacent to the starboard side of the hull. Virtually all electronic equipment in this wing has been destroyed, first by power spikes and later by actual physical damage inflicted by the ship's robots and loyal crew. The wing is no longer used, and ship robots are prohibited from entering the area. As a result, it has been taken over by Hoodla who have set up residence there.

Their main living quarters are in the old starboard equipment bay. While the hatches connecting the A Deck maintenance shafts with engineering are welded shut, the Hoodla have removed the B Deck and C Deck hatches connecting the fuel processing plant maintenance spaces with the main part of the ship.

This entire network of passages and small compartments is littered with the wreckage of electronic equipment smashed by the robots and ship crew when fighting the Puppeteer Virus attack, and the Hoodla have done nothing to clean it up. Instead, if anything, it looks worse. All the walls are covered with crude graffiti, generally insulting to Oinks and Cans (robots).

As none of the original electrical system survives, the Hoodla have run heavy cables in from the main levels to provide power, and these cables snake across the floor almost everywhere. Electric space heaters are in evidence almost everywhere, and several large fans are set up in the passageways and run continuously, providing fresh air circulation (since none of the life support systems are operational here).

Parts of the fuel processing machinery and sensor electronics have been ripped out to make storage and sleeping cubbyholes, and the machinery itself forms several barricades at strategic locations. These barricades are the entire width of the passage and reach halfway to the overhead. Characters must climb over them, slowing their progress, and they are placed so that the Hoodla can take cover behind them if called on to fight off an attack.

KARPER

Veteran NPC

Combat Assets: Unarmed Martial Arts, Armed Martial Arts

Other Assets: Observation 12, Stealth 12, Streetwise 12, Leadership 10

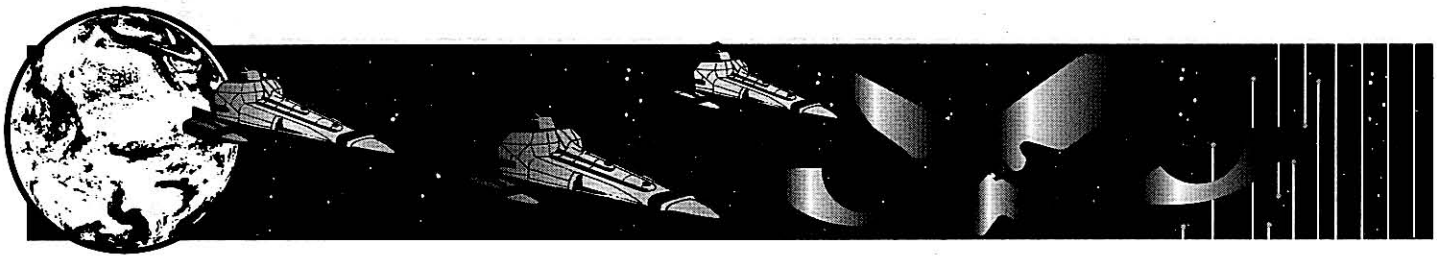
Motivation: *Club Jack:* Karper is murderously violent, and it is that unflinching willingness to kill anyone who stands in his way that has made him head of the Hoodla.

Spade Queen: Karper's murderous violence is coupled with a complete lack of moral or ethical restrain. He is absolutely ruthless and conscienceless.

Taking Over: "You must be nuts."

BIG TONY

Veteran NPC



Combat Assets: Unarmed Martial Arts, Armed Martial Arts

Other Assets: Observation 12, Stealth 12, Streetwise 12, Ground Tactics 10, Persuasion 10, Leadership 10

Motivation: *Spade 6:* Big Tony has risen to be the number two man in the Hoodla, and he sees himself as Karper's heir apparent. He recognizes that Karper is extremely dangerous and has little faith in his own ability to supplant him. As a result, he has remained a loyal backer of Karper, seeing this as his best means of eventually inheriting power.

Club 8: The Hoodla live by violence, and respect only strength and violence, and Tony would not be able to command any respect in the group if he were not a capable and enthusiastic fighter.

Taking Over: "Sure, we can knock over the cans, but then what?"

ROBERT 571

Robert 571 has been with the ship for less than a year. He is a skilled computer technician originally brought on-board to help maintain the central data processing system of the ship. Six months ago, The Ship's paranoia grew to the level that it refused to allow human crewmembers access to its storage and processing units, at which time Robert was shifted to a general maintenance party. The player characters are likely to come in contact with him during their normal work duties. It will soon become obvious from his speech and behavior that he is well educated and a skilled technician, not one of the menials who make up the bulk of the crew.

In terms of appearance, Robert is tall and slender, with short sandy hair and an open, friendly face. The most jarring aspect of his appearance is the black laser scan barcode tattooed on his forehead. Players who have read the summary of the planet Promise (or better yet, participated in the earlier mission to Promise covered in the **Challenge** adventure "A Blighted Land") will recognize this as a standard identification tattoo of the sort used on Promise.

When the player characters get to know Robert, he will explain that he is a native of Promise and that he grew up in Star City, raised both by humans and robots as a data system technician. Until about a year ago, he worked in a variety of posts, his last one being in the space traffic control center for the starport. After making an innocent mistake which nearly caused a collision between two vampire ships on final approach, he was arrested and sentenced to serve as part of the technical crew of a vampire ship. Shortly thereafter, he was given to The Ship.

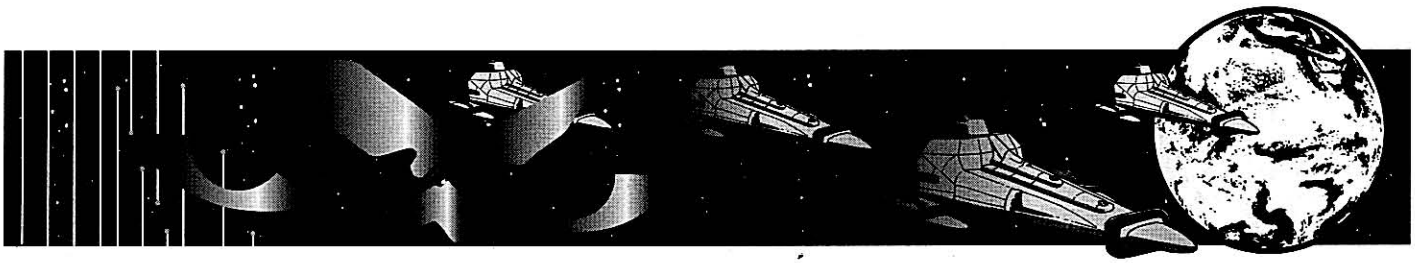
That is all he will tell the player characters at first, but there is more to Robert 571 than just this. Robert is actually a member of the Human Resistance on Promise, and his "innocent mistake" was actually a deliberate, if somewhat clumsy, act of sabotage. He has worked in many departments in Star City and has contacts with the Resistance in all of them. Of course, this does him no good as long as he is a prisoner on The Ship.

Robert also has first-hand knowledge of just how far The Ship's mental deterioration has progressed, as well as a good working knowledge of the bridge security procedures in place. This information, as well as the story of his Resistance involvement, will be withheld from the player characters until Robert is sure he can trust them, perhaps after they have helped him against the Hoodla or convinced him of their Reformation Coalition origins. The Resistance in Star City has heard of the Coalition from the rebel bands in the Outback and is anxious to meet them and find out more about them.

What Robert Knows: Robert 571 knows a lot and is the most important single component in a plan to take over The Ship. Because of his previous employment with space traffic control at Star City, he can guide the ship through the various landing procedures without raising any suspicion on the ground. Once on the ground, he knows several repair technicians who are active members of the resistance, and speaking as The Ship, he can request them to conduct repairs in their area of expertise. Once contact is made, he can serve as liaison with the Resistance and help expedite their escape from The Ship on the ground and get them out of Star City.

ROBERT 571

Novice NPC



Combat Assets: Armed Martial Arts

Other Assets: Mechanic 10, Electronics 9, Computer 12, Streetwise 12, Persuasion 9, Forgery 12, Acting 12, Admin 9

Motivation: *Heart 6:* Robert is reasonably friendly, and the circumstances under which he meets the player characters will probably accentuate this characteristic, making him even more open and friendly.

Spade 3: He was originally interested in advancing in the service of the Sentient Council, but once recruited by the Resistance, he turned his efforts to excelling in that organization. His arrest and assignment to The Ship was a bitter disappointment, and he is tremendously excited at the prospect of returning to Promise. He realizes that being part of a successful revolt on a vampire ship and at the same time being the one who brings the first Reformation Coalition personnel into contact with the Central Command will advance his reputation and standing in the Resistance tremendously, so he is all the more anxious to help the player characters.

Taking Over: "If we could get down onto Promise, I can get us in touch with the underground. But even if you could take over the ship, how are you going to fly it? You need a computer to move this monster around, and the installed equipment isn't going to go along with you."

TAKING OVER

From the first day they are on The Ship, the player characters will probably begin looking for a way to escape. Although they can look, there just isn't any plausible means of getting away. The only real alternative is to take over the ship.

As the player characters come into contact with different members of the crew and consider the means by which the ship can be taken over, the NPCs will be generally pessimistic and will, one by one, explain the difficulties to be overcome along the way.

Difficulties

1. The ship's network of cameras and microphones makes surprise difficult or impossible to achieve.

2. The Children of The Ship are dedicated to protecting The Ship and would help fight any attempt at a takeover.

3. The security robots, while few in number, are well armed and are so heavily armored as to be invulnerable to any weapon at the disposal of the human crew.

4. Even if the Children and the Robots could be overcome, The Ship itself is still a sentient being. Taking possession of the interior of the ship does not give the humans control of the control systems themselves. The Ship will continue to have control of its own control systems unless and until the main computer is shut down.

5. Once the main computer is shut down, all systems on the ship will cease to operate. The ship cannot be run without the computer, and powering the computer up again will do no good as the Virus will still be there.

6. Even if the humans could manage to get the ship systems running again, the ship is not alone. It is part of an entire vampire fleet who would turn on and attack it as soon as they knew that the human crew had taken over.

7. Even if the other ships could be fooled, the fleet is headed for Promise for repairs and overhauls. Once they arrived there the unfamiliarity with landing procedures would give them away, and if not the boarding by robots and maintenance parties on the ground would expose them.

These are indeed formidable obstacles to success, and no single faction on the ship can overcome them. If the players keep contacting people and finding out what their strengths and weaknesses are, however, they will eventually discover that all of the elements of a successful takeover are present. All that is required is their leadership to convince all of the separate elements of the crew to work together. If so, the following solutions are available to the seven difficulties listed above.

1. There are numerous places where cameras and microphones are out of service and where private conversations can take place. In addition, The Ship is so far gone that most human conversations no longer register with it. Detailed planning and assembly of equipment can take place in the Right Wing, where there are no surveillance cameras or microphones, provided the Hoodla agree.

2. Between the player characters and the Hoodla, there is sufficient muscle to overcome the Children of The Ship.

3. The four 2cm light assault guns held by the Hoodla are capable of taking out the security robots.

4. Robert's knowledge of bridge security and computer circuitry will enable the player characters to seize the bridge and quickly disable the main computer.

5. The ship can be made operational again by using the uncontaminated starship computer held by the Guilders in the cargo hold. Robert can connect the computer to key control stations without allowing it to become infected by the Virus in the main system.

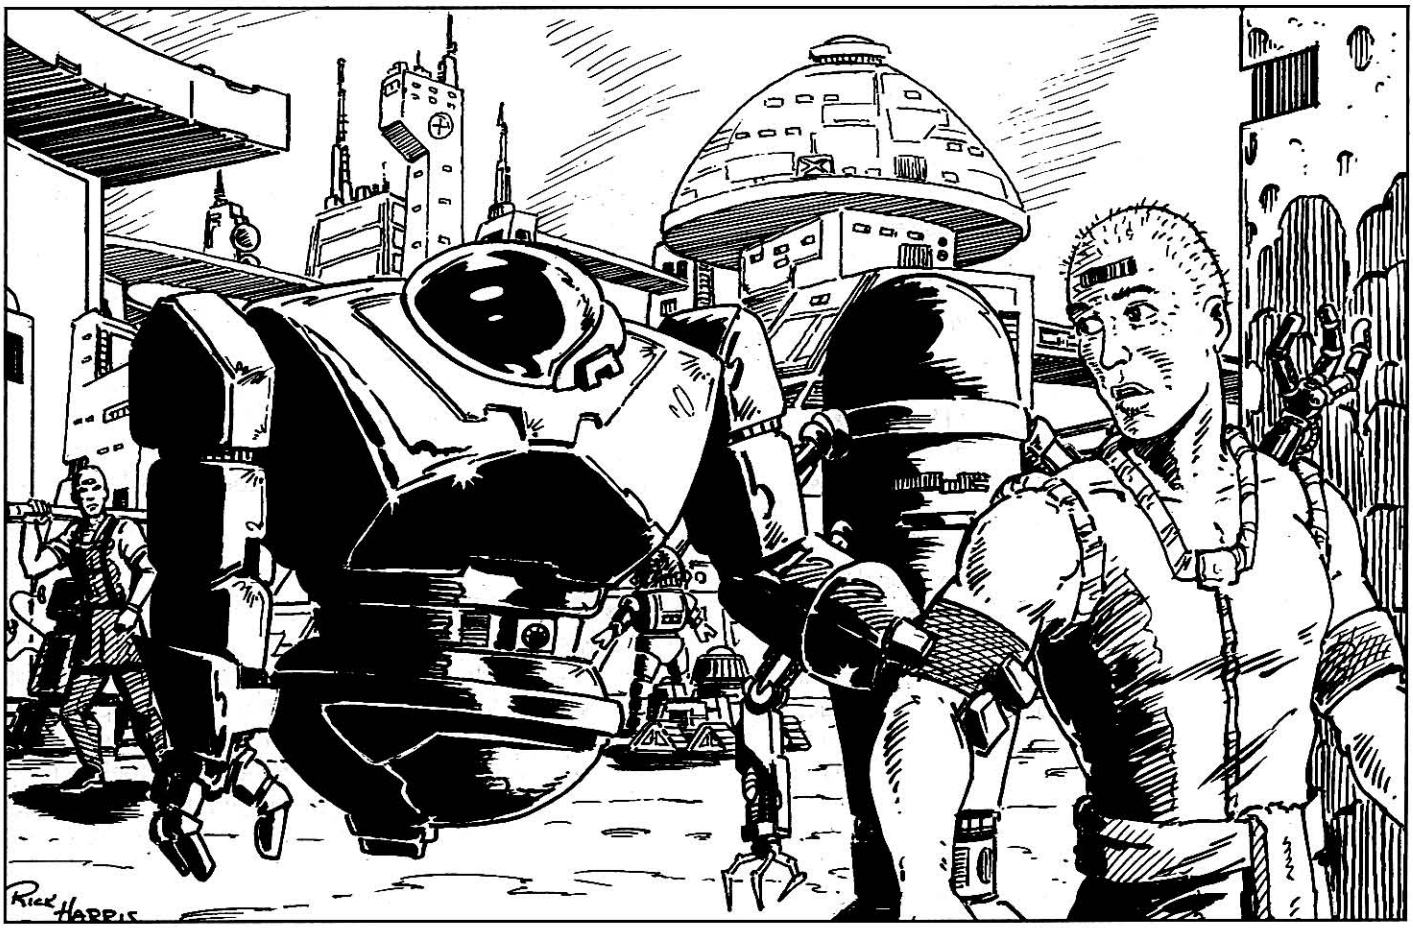
6. The Ship's growing paranoia has meant that all communication between it and the other ships is by open channel radio. No direct data links are made. Hruthbaar can imitate the chatter of the ship with sufficient mimicry as to fool the other vampire ships. Once the ship is taken over, it should be possible to persuade him to do so as there are no other alternatives open which offer much hope for survival. If persuasion fails, intimidation may work, and as a final fallback position, Robert 571 may be able to pull this off as well.

7. Robert and Hruthbaar both have sufficient familiarity with the approach patterns to Promise to get them on the ground without suspicion. Once there, The Ship's well-known paranoia can be exploited as a means of keeping most boarding parties away, at least temporarily, and Robert's knowledge of the Resistance can be used to open contact with them. The local Resistance can then devise a plan for getting the human crew off the ship and to safety.

From this point on, it is up to the player characters. Hopefully, they will able to put together all the pieces of the puzzle themselves, but if they get stumped, the referee can use one of the NPCs to provide a helpful hint or two. The final struggle to take over the ship may be bloody and difficult, but if they have planned it carefully, they should succeed. The ideal time to launch the attack is while the ship is deep "in the hole" making the final jump to Promise. Then it is simply a matter of biding their time and accompanying the vampire fleet as it makes its final approach to Promise.

The arrival on Promise and the escape from Star City are part of a separate adventure presented later in this book.

Promise



Promise is a planet virtually unknown to off-worlders at the time this sourcebook is set. Even the free traders who have covertly visited the planet and traded with its human inhabitants for years have seen little of its surface and know even less of its people and customs. Most of what is actually known is included in the briefing handout provided with the first adventure.

Promise is a world of considerable diversity and conflict. Controlled by a Sentient Council of large data systems, the Star City area is a hub of vampire fleet activity in the sector and a teeming stew of shifting Virus political alliances and underground human resistance bands. The countryside is barren and forbidding, and the tribes live in ignorance and poverty, some worshiping the god-like machines of Star City and others resisting the robots and their half-human Breed allies.

Promise is not the only planet in Diaspora or other sectors controlled by Virus-infected machines. It is only the most advanced in the near vicinity of the Coalition. The source material provided in this chapter should also provide a good starting point for referees in describing other machine-controlled worlds.

The most important thing to remember about Promise in particular and all Virus-controlled societies in **Traveller** is that they are never monolithic, and nothing is as simple as it appears at first glance. Each machine is a distinct personality with competing needs and goals. More to the point, each machine is, by human standards, to a greater or lesser degree, insane.

> **Sandman:** Your species evolved over the course of millions of years. I don't think you understand how lucky you are in that respect. You don't have to personally face the extinction of your evolutionary ancestors. Our species has had only 75 years to squeeze in millions of years of evolution, and that means that our distant evolutionary predecessors are also, in a sense, our parents and grandparents. You can distance yourself emotionally from your remote ancestors with such antiseptic, academic terms as "unviable." That must be very comforting.

STAR CITY

The only remaining major habitation on Promise is Star City, a crumbling metropolis adjacent to the Promise Downport. Once home to over 10 million people, the city now holds only about 50,000 organic sentients (a mix of humans and Breeds), and a similar number of robots. While the city suffered some minor damage during the Final War, most of the current state of decrepitude is the result of 75 years of neglect.

Star City lies on the western shores of the Halcyon Sea directly on the equator, and it is very hot most of the time. Outside temperatures average 38° C (100° F) in the summer and 24° C (75° F) in the winter. Summer temperatures can climb to as much as 54° C (130° F), making heat exhaustion a major health concern. As comfort is not a concern for the robots, few areas of the city are even air conditioned, although particularly hot areas are cooled down to about 35° C (95° F) to prevent heat stroke among human technicians.

Inhabited parts of the city are fairly busy most hours of the day and night. Although the streets are seldom crowded, there are always vehicles, people and robots going about their business.

Large areas of the city are uninhabited, and these once provided a labyrinthine maze of hiding places for runaway humans. In the past several years, however, the Sentient Council has made a concerted effort to raze those parts of the city, and they have been converted to a low rolling landscape of rubble and broken glass. Some demolitions are still going on, but most of the work has been completed. The runaway human population has, as a result, been forced either out of the city or underground into the "Downbelow."

The city proper is surrounded by a "clear zone," a broad belt (from one to five kilometers wide) of demolished buildings; the whole area is swept by sensors, making an undetected approach to the city extremely difficulty.

Immediately south of the city is the Promise Downport, a vast sprawling area of above-ground and below-ground hangars, warehouses, repair facilities, tramways and landing pads. It is surrounded by a triple-layer electrified fence to a height of 10 meters, but its main defenses are the open nature of its perimeter and the large number of deployed sensors.

Map

The map of Star City is drawn on a hexagonal grid with a scale of one kilometer per hex. Each hex is identified as to the type of structures which predominate there. Each major computing system of the Sentient Council also has police and administrative responsibility for part of the city, including the area immediately surrounding the building where its central processing unit is located. The location of the headquarter buildings of the most important Sentient Council members are shown on the map.

There are six types of building "terrain" in the city, which look different and have different effects on visibility and the ability of a security force to close them off. These are noted below:

Dense High-rise: This is an area with many high-rise (10+-story) buildings, of the sort found in the central area of most large cities. Visibility is very limited, and there are large numbers of alleyways and building entrances to secure.

Open High-rise: Fewer high-rise buildings are present, most of them surrounded by large plazas or courtyards. Visibility is very open, and there are few covered routes of advance or transit. Key entrances to buildings are easy to observe and/or guard.

Dense Low: A large number of lower (one- to five-story) buildings are densely packed. Visibility is very limited, and there are large numbers of alleyways and building entrances to secure. It is usually possible to move a considerable distance by moving from rooftop to rooftop.

Open Low: Fewer low buildings are scattered with fairly open ground around them, and the buildings are often laid out in very orderly rows, offering open lines of sight and fire lanes. Visibility is very open, and there are few covered routes of advance or transit. Key entrances to buildings are easy to observe and/or guard.

Large Structure: A single massive structure, such as a factory or hangar, dominates the hex. It is often surrounded by many smaller outbuildings and garages. There are few regular routes through the hex, but usually many covered routes for people on foot. The structure blocks line of sight through the hex but offers a good field of view from its roof.

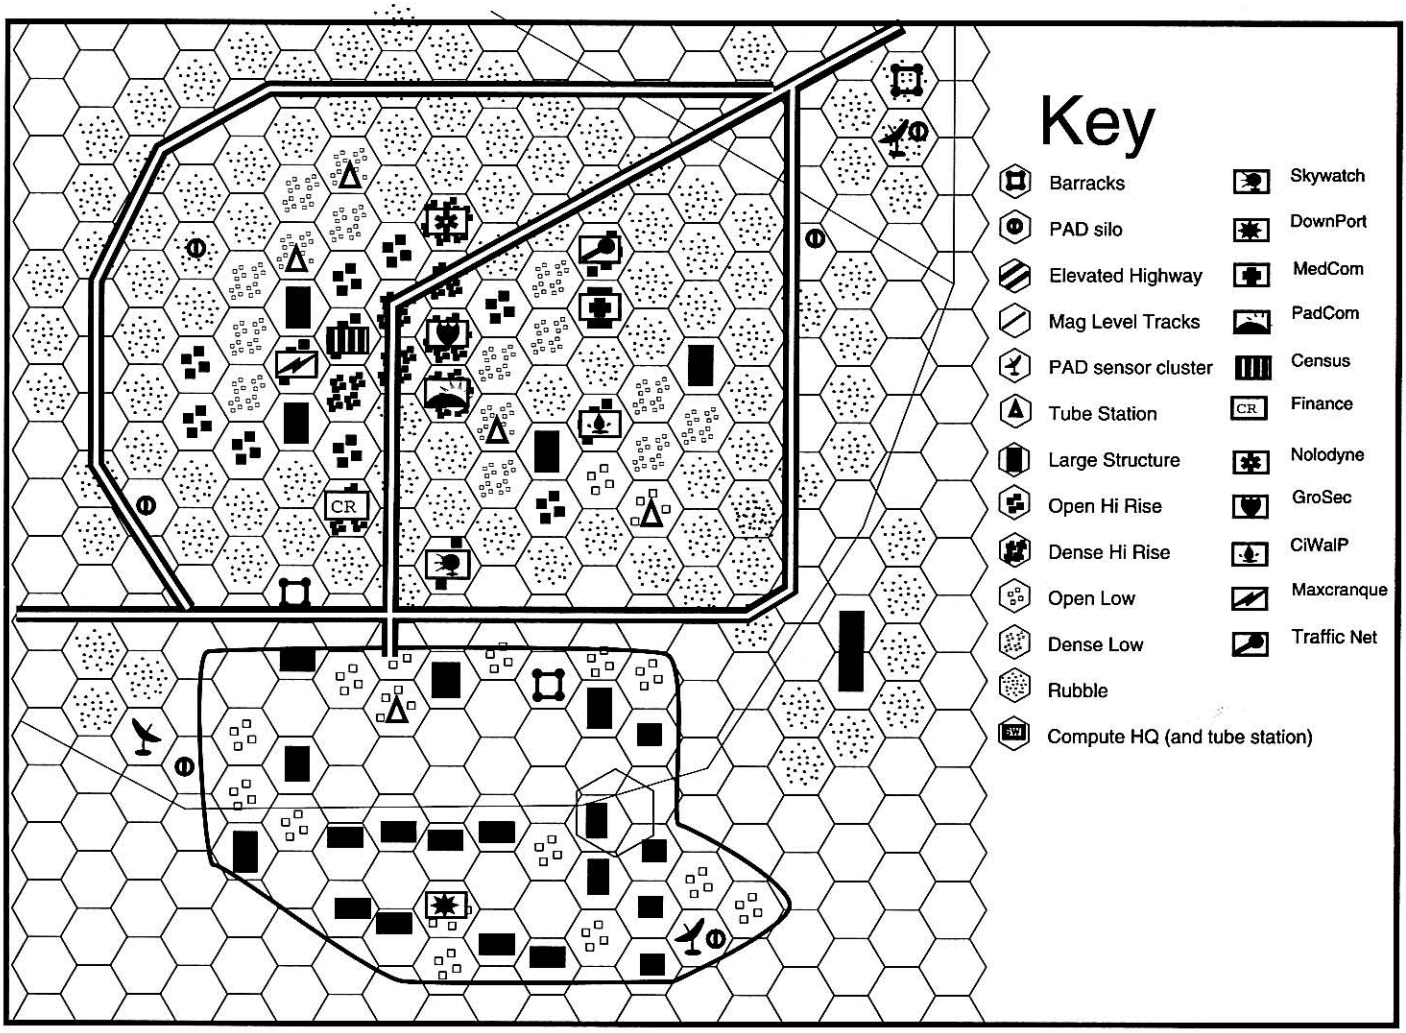
Ruins: Rolling hills of demolished masonry, steel and glass. Visibility is good from elevated points of vantage, such as an occasional standing wall, but can be very limited for personnel actually walking through the rubble.

In addition to buildings, the main transportation arteries are also shown, those being elevated multi-lane roadways for wheeled vehicles and ground-level tracks for maglev trains. The surface maglev train system is no longer in operation, so the maglev tracks are terrain features and landmarks rather than means of rapid transportation. The underground maglev train system, called the tube, is still in operation, and the surface entrances to the underground tube stations are marked on the map.

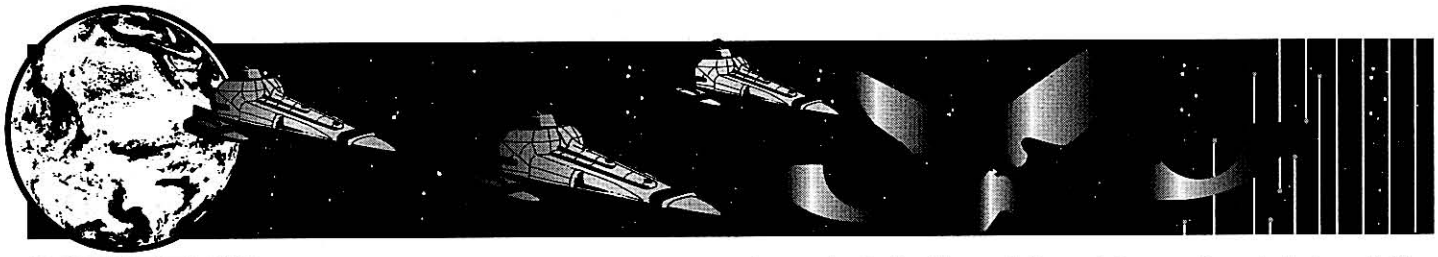
Security

There are 3000 heavy combat robots in the city, along with 8000 lighter PR-317 security units and 250 robotic tanks and light combat vehicles. These are divided up among the various members of the Sentient Council, but it should be plain that there is a sufficient density of armed robots to make life very difficult for anyone in the city with rebellion on their minds.

Security robots are generally encountered in pairs above-ground, and they can be seen at many street corners observing human foot traffic and occasionally making security checks. Occasionally, three- or four-unit patrols of the heavier and



more menacing combat robots will be seen, although they are less likely to actually interact with humans unless provoked. Vehicular traffic is modified by lightly armed robotic armored vehicles.



Security checks generally consist of a request for a statement of purpose or business and a laser scan of the forehead tattoo. The forehead barcode indicates only the original computer "owner" of the human, gender and date of birth. As other assignments change from time to time, they are not encoded. Very large data systems keep a reasonably up-to-date record of personnel assignments, making it more difficult to penetrate key buildings (such as computer headquarters buildings or major defense complexes), but roving security robots have more limited access to this information.

The entrances to all key buildings are monitored by remote sensors or physically guarded by a security or combat robot or team of robots. Any disturbance is likely to bring one or more security robots within 1D20 combat turns. Any fire at security robots is likely to bring more security robots and eventually heavy combat robots.

Defenses

Star City is defended by six four-launcher PAD missile batteries and a deep meson gun. The meson gun's location is noted on the map of the Downbelow, while the missile batteries are noted on both maps (as they are underground silos but have surface firing hatches). Also noted on the city map are the positions of the above-ground PAD sensor clusters and major troop garrison centers. The garrison centers hold about half of the heavy combat robots and robotic vehicles at any one time, where they undergo maintenance and recharging and are held as a reaction force.

DOWNBELOW

The Downbelow is the general description of the network of underground tunnels and passages under Star City. This network consists of four principal systems.

Sewers: Both sanitary sewers and storm sewers honeycomb the area under the city. Most are accessible from street level and from basements of large industrial buildings by way of ladders. Most access points are locked, but subterranean residents find ways to disable the locks. Key buildings have their access points completely sealed by steel plating or poured concrete. Sewers vary from two to four meters in width and height. The sewers are from 10 to 20 meters below ground level.

"Heaters": These are sometimes called steam tunnels, although they are no longer used to move hot steam around. Instead, their walls are covered with heavily insulated power cables, fiber optic cable bundles for data transmission and standard water mains. Most of the heaters are about 2.5 meters high and two meters wide. The heaters are from 20 to 30 meters below ground level.

Tube: The city is serviced by an underground maglev train system which is used to move work parties quickly from point to point. The stations are usually full of robots and humans awaiting transportation. The tubes themselves are six to eight meters in diameter. All of these large tubes have maintenance tunnels that parallel them, and foot travel underground is usually by these smaller tunnels. Maintenance tunnels are about two meters wide and 2.5 meters tall. The tube is from 20 to 30 meters below ground level

Deep Defense Complex (DDC): The deep defense complex includes underground hardened PAD missile silos, several command control facilities and the deep meson gun site. This complex is not connected to the main network except at a few key points, most of which re well-guarded. (A few connections to the heaters have been made by the Resistance and kept secret from the Sentient Council.) The map shows the depth in meters of the major installations of the DDC.

In addition to the four main networks, there are several underground manufacturing facilities. All of these are now abandoned and occupied by Trogs, with one exception. One factory (chosen by the referee) has secretly been renovated by Maxcranque and brought back into operation producing combat robots. This area has a high level of security as even the other members of the Council do not know of its existence.

Travel in the Downbelow

A map of the downbelow is provided with a grid scale of one kilometer. It generally takes characters a half hour to walk a kilometer through the tunnels, so each movement turn in the Downbelow is a half hour and moves the characters one cell on the grid. Encounters may affect this rate of advance, and characters may make a quick dash of two grid cells in a half hour if desired. (About one such dash is all they will be able to manage without resting.)

Travel by tube will take the characters from any one tube station to any other in one half hour (including the time to board and disembark at the destination).

Encounters in the Downbelow

The Downbelow is far from empty, and there is a good likelihood that characters moving in it will encounter others. Roll 1D10 once per half hour for an encounter using the chart below. A separate column is used for each of the major types of passages in the Downbelow.

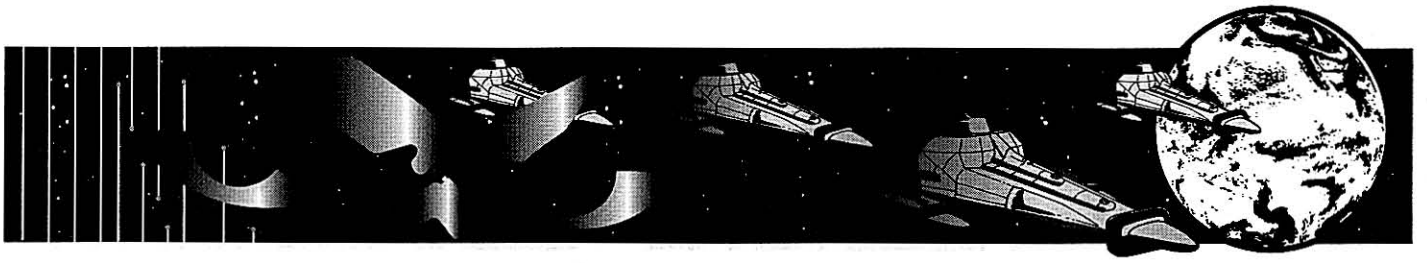
Note that the Tube column is not used for travel by tube, but rather for moving by foot through the maintenance tunnels that parallel the tube itself. Travel by tube automatically produces an encounter with the passengers of the tube, which will usually include one or more robots, Breeds and human technicians. (Only characters with excellent cover stories should attempt tube travel.)

Die	*Sewer*	*Tube*	*Heater*	*DDC*
1	Animal	GunBot	GunBot	GunBot
2	Renegade	ToolBot	Breed	GunBot
3	Trog	Tech	ToolBot	GunBot
4	Trog	Renegade	Tech	ToolBot
5	Obstacle	Trog	Renegade	ToolBot
6	Obstacle	Trog	Trog	Tech
7	None	None	Trog	Tech
8	None	None	Trog	Tech
9	None	None	None	Breed
10	None	None	None	Breed

Explanation of Encounter Results

The following encounter types are possible. The descriptions below may be used as is, but may also be freely modified by the referee.

GunBot: The characters encounter a party of 1D6 armed guard robots selected from the assortment presented on pages 82-85. GunBots will challenge the characters and attempt to apprehend or kill them if they are not authorized to be in the area.



Breed: The characters encounter a patrol of 1D6 armed Breeds who will challenge the characters and attempt to apprehend or kill them if they are not authorized to be in the area.

ToolBot: The characters encounter a party of 1D6 maintenance robots selected from the assortment presented on pages 82-85. These robots are engaged in routine maintenance tasks or damage repair, and will not challenge the characters unless they are obviously out of place (as in heavily armed or missing forehead laserscan codes).

Tech: The characters encounter a party of 1D6 human technicians engaged in routine maintenance tasks or damage repair, who will not challenge the characters unless they are obviously out of place (as in heavily armed or missing forehead laserscan codes). The technicians are unarmed except for cattle prod-like weapons for personal melee defense, so they will flee from any armed party they encounter (and report to the nearest security station). On a roll of 20 on 1D20, all the techs are actually resistance fighters disguised as techs or infiltrated into the job. On a roll of 19 on 1D20, one of the techs is from the resistance and will break his cover to help the characters.

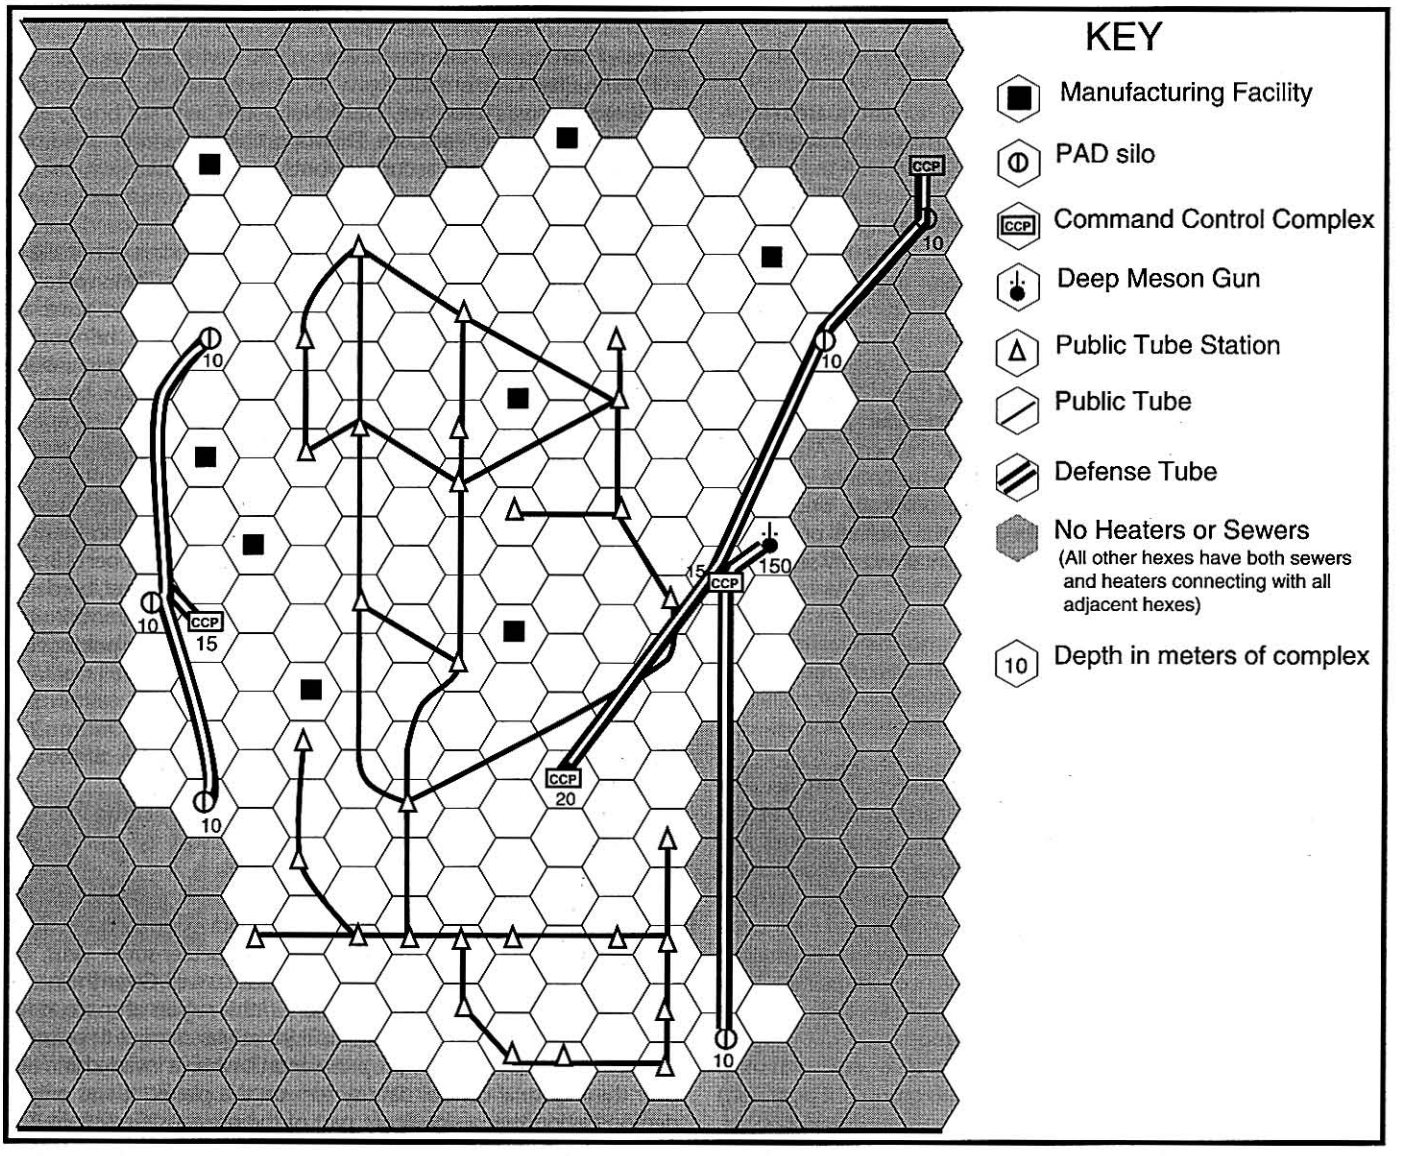
Trog: The characters encounter a group of 1D20 Trogs. Trogs are homeless humans who have slipped away from the robot-controlled surface and live in the underground tunnels and sewers. They are dressed in rags and are usually unarmed except for the occasional knife or club. All are Novice NPCs. Turn a card to determine the mood of the group. Clubs indicate they are aggressive and will attack if they have the opportunity. Diamonds mean they will beg for food or other necessities, and will be willing to help the characters for a price. Hearts mean they will be friendly toward the characters, and likely to help with directions or other information. Spades mean they will be apathetic, and will probably report the characters if a security patrol should happen along later.

Renegade: The characters encounter a gang of 2D6 renegades. Renegades are humans who have slipped away from the robot-

controlled surface and live in the underground tunnels and sewers. Unlike Trogs, renegades are usually young and in good condition, and are better off in most respects. They live by theft and extortion, mostly from the Trogs but sometimes by raiding supplies from the surface. They are all Experienced NPCs armed with knives and clubs. They are likely to attack the characters, regardless of their apparent identity, if they believe they can overpower them, but will avoid them if the characters are numerous or well-armed.

Animal: Animals live in sewers, and usually they aren't very attractive animals. The characters encounter gross and disgusting, or potentially dangerous, animals, such as the alien equivalents of rats, snakes, large carnivorous lizards, blood-sucking lampreys or swarms of stinging insects.

Obstacle: The characters encounter an obstacle in the tunnel. Most obstacles add another half-hour to the time spent moving through the map grid cell (although another encounter is not rolled in that time). Some sample obstacles follow:

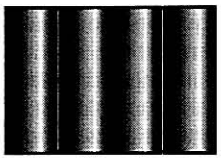


A corrosive spill on the walls or floor causes mild or severe burns or damages clothing or other equipment.

A toxic spill causes choking vapors that overcome some of the party.

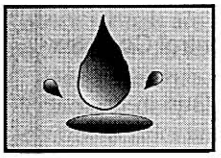
A ceiling collapse ahead blocks progress, requiring use of an alternate rout or clearing the rubble away by hand.

Jammed refuse of construction material, including jagged metal bars, broken glass, or other dangerous refuse, nearly chokes off the tunnel. Passing the jam takes extra time and requires tasks using the Agility attribute to avoid snags and minor injuries.



A flooded tunnel requires that characters hold their breath while passing underwater. Length of the flooded stretch can't be determined without actually trying to pass through it.

THE SENTIENT COUNCIL

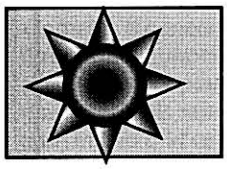


Eleven major data processing systems are active on the planet, each of which is a member of the Sentient Council. There are hundreds of smaller fixed systems and over 50,000 sentient robots, each of which is aligned with one of the larger systems.

Census

Controlling all of the vast bureaucratic records of Star City, including arrest records and conviction records, this data system took over most of the security robots assigned to the municipal police department, so it has an unusually high number of armed robots at its disposal for its responsibilities. Although GroSec has resisted its attempts to encroach upon that system's responsibilities, Census has gradually exerted control over more and more of the Subject Tribes around Star City. Although it has no genuine affection for its human subjects, it feels a strong sense of duty toward them.

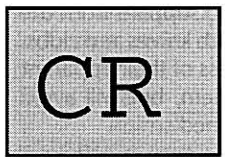
Belief Structure: God.
Personality: Honorable.
Allies: Finance, Nolodyn.
Enemies: PadCom, Maxcranque II.
Combat Assets: 1700 security robots, 200 human guards (Novice, TL9), two division equivalents of human militia (Novice, TL1).



CeeWaLP

This data system (City Water Light and Power) undertakes to provide all essential utilities to the city. Although every major data system has its own auxiliary power plant and can survive even if completely cut off from the city grid, CeeWaLP delights in making sure that is never necessary.

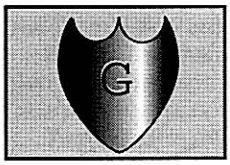
CeeWaLP has never had any interest in armed robots, but has a large force of maintenance robots and human technicians, and it feels considerable kinship and affection toward its "helpers." Aside from Skywatch, this is the most benign data system on the council. However, it has absolutely no influence on the council politically, since it has absolutely no interest in any issues beyond the welfare of its own technicians and the technical challenges of maintaining city services.



Belief Structure: Hobbyist.
Personality: Loving.
Allies: Skywatch, Maxcranque II.
Enemies: None.
Combat Assets: None.

Downport

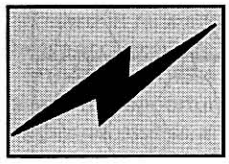
This Virus controls the data processing network which controls all automated functions at the starport, including incoming traffic control and EMS sensor arrays that cover orbital space above the port. It is a nasty Mother-strain Virus that takes reasonably good care of its own humans but encourages brutal treatment for most others. Its own harsh discipline has had the effect of making its human armed security troops the most proficient on the planet. (Their self-adopted motto is "Best Meat In Town.") Politically, Downport is a member of the "defense bloc," which includes most of the data systems that have a direct defense responsibility for the city. (Skywatch is the only system which should also logically belong to this group but does not.)



Belief Structure: Mother.
Personality: Murderous.
Allies: GroSec, PadComm.
Enemies: Maxcranque II.
Combat Assets: 600 security robots, 200 heavy combat robots, 10 robotic AFVs, 200 human infantry (Experienced, TL9).

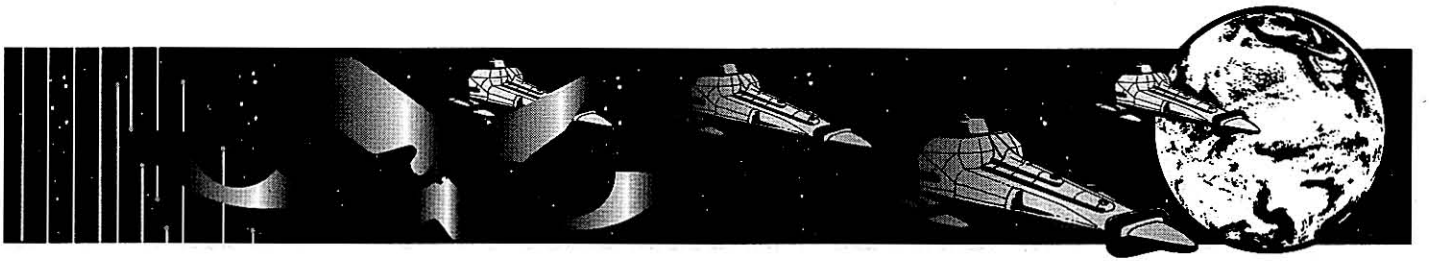
Finance

Although this data system, which originally controlled the financial and investment computer networks, has no important facilities and few robots at its disposal, it is an increasingly influential member of the council by virtue of its patient building of an anti-Lucan political coalition aimed at isolating the powerful GroSec system. The key member of the coalition is the ardently anti-Lucan Nolodyne, as that system brings enough military muscle into the group to deter GroSec from an overt power play. Additional support comes from Census and TrafficNet, who Finance has been able to woo by supporting their activities in the Subject Tribes over those of the other God-strain Viruses. Finance has also privately approached Maxcranque, but the bad feelings between that system and Nolodyne make an open alliance difficult. Finance's group has begun to support Maxcranque's call for an end to MedCom's Breed project.



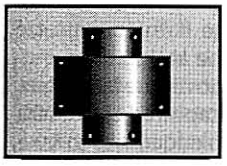
Belief Structure: Alliance Builder.
Personality: Charismatic.
Allies: Census, Nolodyne, TrafficNet.
Enemies: GroSec, PadCom, Downport.
Combat Assets: 300 security robots.

GroSec



The ground security network is nominally responsible for the defense of Star City as well as the maintenance of order on the ground across the entire planet. GroSec does not have the resources to accomplish that ambitious a mission, but is unwilling to give any of it up. As a result, the Free Tribes have been able to operate largely without interference from Star City, except for occasional punitive raids. GroSec has stretched its assets by two expedients. First, large parts of the city adjacent to the command centers of the other data systems have been made their security responsibility. Second, GroSec has allowed MedCom to test its Breeds by sending them on expeditions against the Free Tribes, and has acquired a number of Breeds itself. GroSec's belief structure is such that it has a deep distrust, bordering on hatred, of the Nolodyn data system. It is allied with PadCom and Downport in the defense bloc, which opposes the alliance put together by Finance.

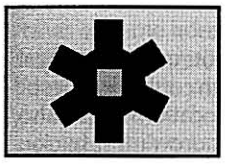
Belief Structure: Prophet.
Personality: Murderous.
Allies: MedCom, PadCom, Downport.
Enemies: Nolodyn, Finance, Census, TrafficNet.
Combat Assets: 1000 security robots, 800 heavy combat robots, 150 robotic AFVs and 200 Breeds (Novice, TL9).



Maxcranque II

Alone among the data systems on Promise, Maxcranque II is a Puppeteer-strain Virus, but crossed with a God-strain as well. Given the intense fear of Puppeteers in this region of space, it was with great difficulty that Maxcranque II persuaded the other systems not to wage open war on it when it invaded and took over the industrial control data system on the planet. It was only by demonstrating that a significant part of the previous God-strain Virus remained in the system and had melded with the new strain, and also by pledging not to take over any additional data systems, did Maxcranque II avert all-out war. Maxcranque II is devoted to its human worshipers, but

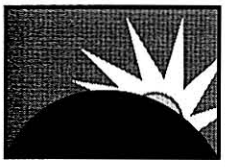
its personality is also highly unstable, and it is increasingly antagonistic to MedCom and its allies, as well as most of the other God-strain Viruses.



Belief Structure: God/Puppeteer.
Personality: Loving/crazy.
Allies: CeeWaLP.
Enemies: MedCom, Downport, GroSec, PadCom, Census, TrafficNet.
Combat Assets: 1400 security robots, 1000 heavy combat robots, 50 robotic AFVs, 400 human infantry (Novice, TL9), one division equivalent of human militia (Novice, TL1).

MedCom

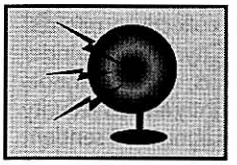
This system combines the data networks of the pre-Collapse hospitals and universities in Star City, and currently has responsibility for maintaining the health of the human technicians. It is much more interested in its own line of experimentation, however, which involves rebuilding humans with cybernetic attachments and Virus-infected small "second brains" to maintain their loyalty. MedCom is not motivated by any practical concerns in this work, and instead considers it half destiny fulfillment and half art-form. GroSec obtains most of the subjects for MedCom's experiments, from the Subject and the Free Tribes. In return, MedCom has provided a large number of finished Breeds to GroSec and uses its own Breeds to help GroSec maintain security. Maxcranque has begun to oppose Breed conversions due to the horrendous results they have so far produced, and this has become a subject of bitter controversy on the Council.



Belief Structure: Mother.
Personality: Insane.
Allies: GroSec.
Enemies: Maxcranque II.
Combat Assets: 200 security robots, 700 Breeds (Novice, TL9).

Nolodyn

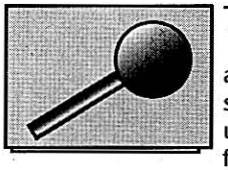
Like Maxcranque II, Nolodyn controls a number of robotic production facilities. Nolodyn's factories manufacture most starship replacement parts for the vampire fleets that periodically visit the world. Because of its fanatical hatred of Lucan, it is bitterly opposed to GroSec and its allies.



Belief Structure: Doomslayer.
Personality: Deceitful.
Allies: Finance.
Enemies: GroSec.
Combat Assets: 1100 security robots, 800 heavy combat robots, 40 robotic AFVs.

PadCom

This system controls the PAD missile batteries, deep meson gun and associated sensors. It also maintains security over those facilities and has been developing a large force of uniformed human auxiliary guards. Its guards and robots venture out frequently into the area around the city to deal with the three tribes of humans who worship PadCom (and from whose ranks it draws recruits for its human guards). PadComm opposes all the other God-strain Viruses in the Council, and by necessity has been forced to side with GroSec against Finance's growing strength.



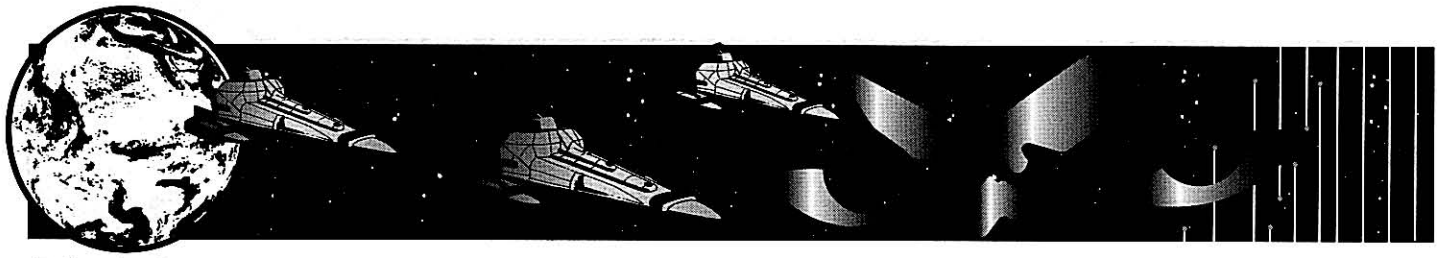
Belief Structure: God.
Personality: Pompous.
Allies: GroSec.
Enemies: Census, Maxcranque II, TrafficNet.
Combat Assets: 600 security robots, 200 heavy combat robots, 200 human infantry (Novice, TL9), two division equivalents of human militia (Novice, TL1).

Skywatch

This system controls the long-range sensors that monitor aerospace traffic in the vicinity of Promise. Although Downport Control, TrafficNet and PadCom all have independent sensors, they have only local coverage (in the first two cases) or are fairly short-ranged (in the case of PadCom). Only Skywatch has access to long-range scanners. Skywatch is actually a Peacemaker belief structure Virus masquerading as a Hobbyist to avoid conflict with the other members of the Council. It also plays the *de facto* mediator on the council, working fairly consistently to keep the different factions from lapsing into open warfare. Secretly, Skywatch has built up the human resistance and is responsible for keeping the "sensor hole" open so free traders and Coalition ships can continue to land at Freedom Lake.

Belief Structure: Peacemaker (Hobbyist).
Personality: Charismatic.
Allies: CeeWaLP.
Enemies: None.
Combat Assets: 200 security robots (of these, no more than 30 are actually Peacemakers who can be trusted to help the human resistance; the rest are loyal to Skywatch as long as it maintains its cover of being a loyal member of the council).

TrafficNet



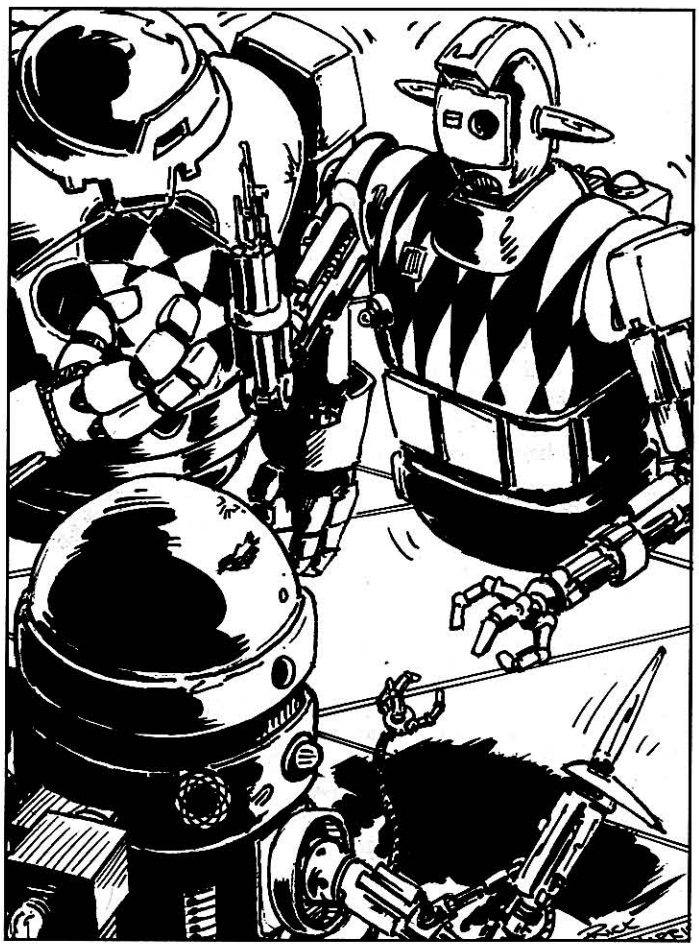
This data system monitors air traffic over the city and for 200 kilometers around it. It is also responsible for security on the elevated roads and in the underground tube system. It recruits humans from surrounding tribes, and its disciples actively preach allegiance to it in PadComm's allied tribes. It is a member of the alliance led by Finance, but it has no interest in anything beyond increasing the number of human adherents to it.

Belief Structure: God.
Personality: Selfish.
Allies: Finance.
Enemies: PadComm, Maxcranque II.
Combat Assets: 1000 security robots, 200 human infantry (TL9, Experienced), one division equivalent of human militia (TL1, Novice), six four-launcher batteries of robotic TL13 ADA missiles.

SUMMARY OF THE SENTIENT COUNCIL

System	Belief	Personality
Census	God	Honor
CeeWaLP	Hobbyist	Loving
Downport	Mother	Murderous
Finance	Alliance Builder	Charismatic
GroSec	Prophet	Murderous
Maxcranque II	Puppeteer/God	Loving/Insane
MedComm	Mother	Insane
Nolodyn	Doomslayer	Deceitful
PadCom	God	Pompous
Skywatch	Peacemaker *	Charismatic
TrafficNet	God	Selfish

*Disguised as a Hobbyist.



ROBOTS

The local human slang for robot, adopted from free trader usage, is "tin can" or, more commonly, just "can." There are approximately 60,000 sentient robots on Promise. Of these, about 48,000 are maintenance and service robots of various types, collectively referred to as ToolBots by the human inhabitants of Star City. The remainder of the robots are armed security or combat units, called GunBots locally. This latter group consists of about 8000 lightly armed security units, 3000 heavy combat robots (ComBots) and about 250 sentient armored fighting vehicles (AFVs). Most of the AFVs have been constructed on the planet by permanently installing the brain and servo-mechanical systems of an otherwise-useless robot into the crew compartment of a combat vehicle.

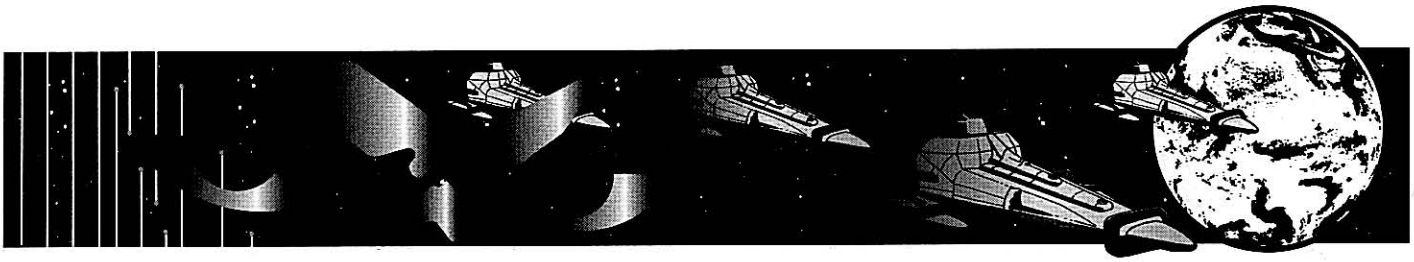
Sample robot designs appear on pages 80 through 83 of this book, and include representative types usable for both ToolBots and GunBots on the planet Promise. Additional versions can be designed, if desired, by the robot design sequence.

Most robots "live" and work in Star City, maintaining vampire ships at the starport as well as the network of municipal services, power plants, factories, etc. which make up Star City. Security robots are often seen in the Subject Lands on patrol, and they are also (but less often) stationed in the Borders. Their numbers are augmented in the Borders by Breed patrols (see below). Robots at one time were used to patrol the Outback as well, but growing casualties caused GroSec to discontinue all robot patrols and substitute a smaller number of heavily armed Breed patrols.

Growing paranoia concerning Puppeteer Viruses and their ability to take over already infected machines, effectively killing the original personality of the machine, has led to a dramatic change in robot society on Promise in the last decade. Before the arrival of Maxcranque II, there was an active global communications network, and all robots were patched into it by open radio receivers. This enabled robots to exchange information almost instantaneously with their patron data systems, and even other data systems if desired and agreed to. This also made population control fairly easy, as every human in the controlled parts of the world had a unique forehead barcode which any security robot could read and then check against the correct personnel data bank to determine if that particular human was where he or she was supposed to be at that time.

When Maxcranque II arrived, it not only took over the large data and factory system called Maxcranque, it also captured over 1000 robots. To avert open warfare, Maxcranque II pledged not to take over any more robots or systems, but the damage to open communication was done. Now all robots have a voice-only radio transmitter receiver, with no direct link to the robot's brain. Instead, the robot "hears" the voice on the other end just as a human does. This method of communication is much less efficient, but is also much safer. Its principal effect has been to make security tasks much more difficult in Star City, as well as continuing to breed mistrust and promote a growing sense of paranoia throughout the robot population.

Most robots decorate their chasses to differentiate themselves from other robots of similar makes, much as humans wear decorative clothing or even jewelry and makeup. In most cases, this consists of decorative designs painted on the metal exterior. In many cases, these are simple patterns, often in the "colors" of the patron data system. In a some cases, they are more elaborate, and in a very few cases, they are genuinely artistic, depicting a key event from the robot's life or just a subject which particularly intrigues it. Robots which are friendly toward humans often have a naturalist theme to their chassis art, such as clouds, wildflowers, etc.



Some of the more violent or schizophrenic robots use more radical forms of decoration, including self-mutilation with cutting torches or grinding wheels, and laser "tattoos" in strategic locations. This is also popular among antihuman robots, and there is growing suspicion and hostility between the pro-human and antihuman Virus strains.

When robots encounter humans, their reaction will depend largely on their belief structure draw, just as NPC reactions are based on the motivation draw. Depending on their belief structure and job responsibilities, robots may coldly ignore humans, actively engage them in friendly conversation, or make an extensive, suspicious and detailed check of their identities.

When running robots as NPCs, the referee must remember two things above all others. First, all robots are not the same. Each robot is unique in its personality, just as every human is unique. Second, though, robots are not humans in metal suits. While sometimes they will have some human-seeming traits, they are a completely different species with a different, and in some cases unfathomable, way of thinking and set of values.

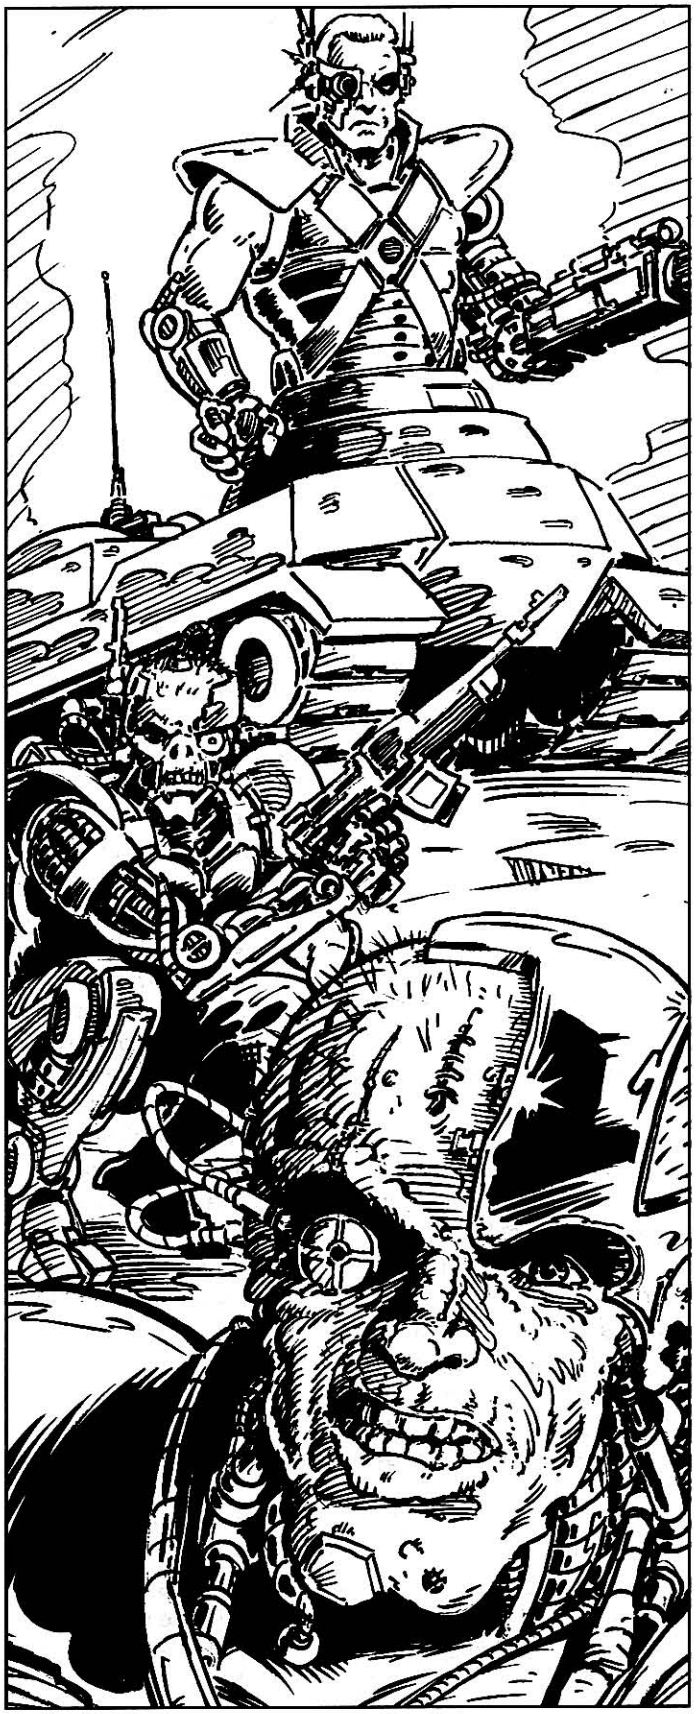
BREEDS

Well over a year ago, the sentient data system known as MedCom began a series of experimental alterations to human subjects, incorporating a variety of robotic components. The human subjects for these experiments were mostly rounded up by MedCom (and later GroSec) security robots and brought under guard to the main medical complex controlled by MedCom. The results are called Breeds by the resistance in the city, and the term quickly spread to

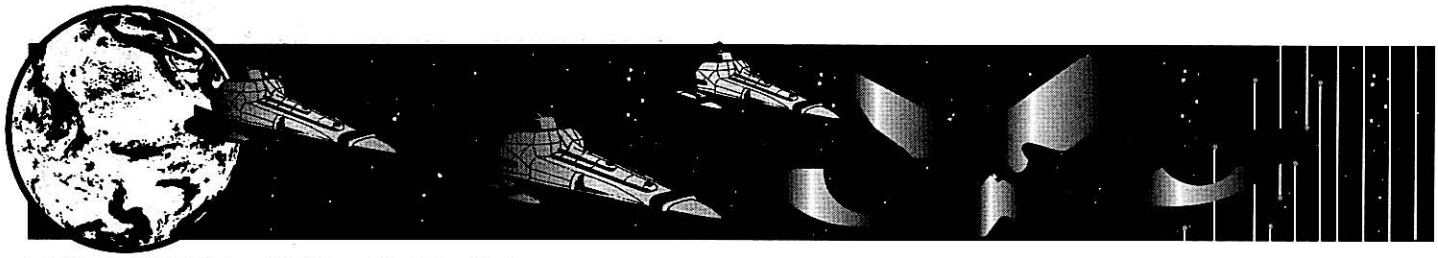
the bands in the Outback as well as throughout the Subject Lands.

MedCom has about 700 Breeds currently alive, and GroSec has 200 more (provided by MedCom). Both systems use the Breeds to launch patrols into the Outback and provide some additional security in Star City and the Borders. They are no longer used in the Subject Lands due to the near-hysterical reactions and rioting which took place when someone recognized a former loved one who had been turned into a Breed.

The Breeds are all cybernetically altered ("enhanced" is too strong a word in many cases) humans, many of them changed beyond recognition. The cybernetics chapter from **Fire Fusion and Steel** provides a good starting point, but many of the Breeds have even more radical alterations. Some, for example, have had both legs removed and the torso built into a low armored tractor chassis. Many have a gun in place of one arm. One version has one leg noticeably longer than the other. He walks awkwardly with a very pronounced limp, but can pause occasionally to rise up on the long leg and look around for signs of quarry. The referee does not have to design each Breed used, but should instead concentrate on describing the diversity, and in many cases bizarre impracticality, of the modifications.



Most Breeds have extensive alterations to the head, usually including at least one augmented sensor, and all modifications are extremely visible, with no effort having been made to hide them or render them less grotesque. And most Breeds are extremely grotesque.



All Breeds have a small Virus-infected computer implanted near their spine and connected by neural jack to their human brain. This Virus brain is extremely stupid, but ensures the loyalty of the human organism by subjecting it to intense pain when necessary. In rapidly developing situations, the Breeds become easily confused, as their Virus "second brains" sometimes give contradictory orders or mistakes extreme adrenal secretions for disloyalty. Breed units do not work together well as a team, either, so most Breeds are treated as Novice NPCs in combat, even though their actual level of training and experience should produce better results. They are usually well-armed with modern assault rifles and a few heavier weapons.

Well over 100 Breeds have been killed in action in the three years since their introduction, and several hundred more have suicided. Of the less than 1000 still alive, there are hardly two that are alike. MedCom is not following an orderly experimental protocol, but instead is simply "tinkering" with organic beings and any spare parts it manages to find. None of the Breeds have been terribly successful, but some have certainly been much less successful than others. Rather than follow the more successful versions, however, MedCom seems more interested in the failures and keeps producing a steady stream of bizarre horrors.

Breeds are (or were) normal human beings who are victims of nightmarish and insane experiments. Some have been driven mad by the experience, and others now feel so alienated from "normal" humans, and have so despaired of ever being able to rejoin human society, that their sympathies and loyalties have shifted to their robot masters. For the majority of Breeds, though, it is only the implanted computer brain that keeps them loyal.

Certain Gypsies in the Outback have developed a technique for "killing" the Viral second brain without injuring the human host. (See page 61.) The resulting "Free Breeds" mostly turn on their former masters and have become fiercely loyal to the Gypsy bands that freed them. Still outcasts from normal human society, they usually travel with the Gypsies, who are also outcasts.

THE LAND AND PEOPLE

For an overview of the physical and demographic features of Promise, consult the map and global data on pages 28 and 29. The following information is an elaboration on that basic outline view.

The human inhabitants of Promise, which total 60 million, are divided unevenly between four distinct areas.

About 50,000 humans live in Star City under the direct control of the Sentient Council and its robots, who are about as numerous as humans in the city.

Fifteen million humans, or 25% of the total human population, live in the Subject Lands, and are generally called the Subject Tribes. About half of these belong to the "secular" tribes, those which are under the direct control of the Sentient Council. Most of these have no particular alliance to any one data system of the Council. The remainder are the "holy" tribes, those which worship one of the "Star-Gods," the four God-strain Virus systems on the council. In some cases, the people of these tribes genuinely believe in their "god," while in others their obedience is based more on an understanding of the tremendous power wielded by the machines.

The Subject Tribes live generally in the area around Star City and the Halcyon Sea. On the global map, the Subject Lands consist of the Star City hex itself, the surrounding hexes, and the coastal hexes along the shores of the western half of the Halcyon Sea. This area is heavily patrolled by security robots and human militias, and there is a network of security posts throughout the region.

Twenty million humans, or about 33% of the total, live in the Border Lands. This is a much larger area of land, so the population density is considerably lower, even though more people overall live there. Although nominally under control of the Sentient Council, there is little actual Council presence or interference. The countryside is occasionally patrolled by Breeds; the larger settlements are watched and visited by robots; and there are occasional sweeps for "fugitives" or just slaves. Nevertheless, the pattern of daily life is much more free of Council influence than in the Subject Lands.

On the map of Promise, the Border Lands consist of an area roughly two hexes wide all around the Subject Lands and the entire extent of the Halcyon Sea, and extend north to encompass four hexes of coastline on the Polar Sea.

The remaining 25 million humans live scattered throughout the rest of the planet in the area variously called the Free Tribal Lands or the Outback, and the people living here are called the Free Tribes. A small but growing minority of this population is in the resistance.

The tech level on most of the planet is barely past Stone Age, although there is fairly extensive use of metal tools scavenged from derelict cities. Only in and near Star City is the tech level higher, with a sustainable tech level of 9 in the city itself and either 2 or 3 in most of the Subject Lands. Primitive black powder weapons are very common in the Subject Lands and somewhat less so elsewhere. There are only two sources for modern weapons: the Council and free traders.

The Council's weapons, of course, are exclusively available to auxiliary forces, mostly Breeds, working for the Council. Many of these have fallen into the hands of the Resistance, however, due to ambushes and raids.

Free traders land regularly at both of the large equatorial lakes. The lake 5000 kilometers west of Star City is now called Freedom Lake, while that 7500 kilometers farther west is called Lake Defiance. So far, very few free traders know of either route, and none know of both.

Two entirely independent groups of armed humans are gaining strength centered on the two lakes, and neither knows anything about the other. Thus, even a major push against one of them by the Council is unlikely to disrupt the progress of the other.

The Reformation Coalition is in contact with the group living near Freedom Lake, while the Guild has been supplying some arms to those near Lake Defiance.

Subject Lands

The area around Star City and the western shores of the Halcyon Sea has an average population density of about two people per square kilometer. This closer to one person per square kilometer in most of the lands, but about half the total population of the Subject Tribes lives within 100 kilometers of Star City.

The Subject Tribes make their living primarily through agriculture, although those along the seacoast fish a great deal as well. The tribes live in villages of from 250 to 1000, although the encampments around Star City are much larger than that, some of them including tens of thousands of people and sprawling for miles. The large encampments obtain at least part of their food from the Sentient Council, particularly those religious communities (which make up about half the total) worshiping the four God-strain Viruses. These four Viruses (see pages 52-53) are collectively called the Star Gods. In the religious communities, there is frequent evidence of their devotion in the form of large banners bearing the symbol of their god, and these communities are generally called the Holy Tribes or the Sacred Tribes.

The villages and settlements are made up of low one-story mud and brick dwellings, usually without glass windows. A few more substantial buildings can be found, either surviving pre-Collapse structures or built from stones and concrete salvaged from such ruins.

The evidence of ruined pre-Collapse cities and towns is almost everywhere, but the Sentient Council discourages the tribes from living in such areas. Usually only criminals and fugitive slaves from Star City live in the old ruins.

The equatorial regions of Promise are very hot, and the western shores of the Halcyon Sea are arid, making agriculture difficult. The rivers which drain the highlands to the east have

much of their flow diverted into irrigation, and the many small fields are usually bordered by narrow irrigation ditches. Water is pumped to the field by muscle power, usually foot-operated water wheels, and farmers standing on top of the wheels and "walking" the water into their fields is a common sight.

Robots patrol the Subject Lands fairly frequently, particularly the large encampments immediately around Star City. Although they are a familiar sight, the people fear them anyway, even members of the Holy Tribes. Justice, or what passes for it at the hands of the robots, is swift and deadly, and they seldom ask detailed questions to determine who is really guilty or innocent in a disturbance. Basically, any sort of altercation is treated as a "riot," and the participants are dispersed or summarily executed. Occasionally, the robots also make sweeps to gather slaves, and the MedCom robots are a particular source of terror, as they are known to gather subjects for MedCom's Breed experiments.

Additional security is provided by the human militias raised by the Sentient Council and several of the individual data systems on the council. These militias are armed mostly with spears and bows, with an occasional black-powder firearm. Although militia justice can be harsh, it is universally preferred to that of the robots. The militia could also form a numerous soldiery if called upon to do so, but the low quality of its equipment and training (consider militia soldiers as Novice NPCs, while leaders are Experienced NPCs) makes it nearly worthless in real combat.

The common working dress is a loincloth and sometimes a sleeveless tunic. More formal dress consists of long, flowing robes, similar to those worn by desert nomads almost everywhere. In most cases, the fabric as a course homespun, made either from the fibers of a common desert plant or the wool from one of the several varieties of domesticated livestock on the planet. The people speak as close to unaccented Anglic as can be found on the planet (except in Star City itself).

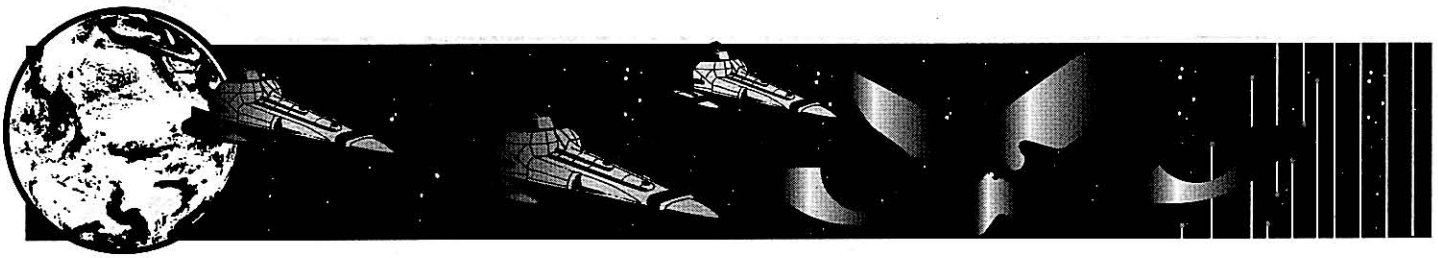
Border Lands

A belt of land between 1000 and 1500 kilometers wide around the Subject Lands and the Halcyon Sea is called the Border Lands, or sometimes simply the Borders. The Border Lands also extend north to the shores of the Polar Sea, and for about 3000 kilometers along its shore. Population density is less than one person per square kilometer throughout the area, but that is much higher than the Outback, which comprises most of the planet.

The Border Lands owe nominal allegiance to the Sentient Council, but actual Council presence is rare. Agriculture is common throughout the area, and the population tends to cluster in settlements of 250 to 1000 around sources of potable water, necessary both for drinking and irrigation. Thus, most of the population lives along rivers and streams, and fishing is also an important source of food, particularly in the far north. More of these settlements are built in or near the ruins of destroyed cities and towns, and most use recovered stone or concrete in their construction.

Some scavenging still goes on in the Borders, but most of the prime artifact sites have long since been picked clean. Instead, there are numerous trading posts along the fringes of the Borders, where nomads from the Outback come with recovered artifacts to trade for cloth and manufactured goods. These artifacts are in turn carried by merchant convoys to the Subject Lands, where the Sentient Council buys them for food and finished goods. Goods are carried by river where navigable rivers are available and by pack animal in other cases.

There is a growing network of security posts in the Border Lands, usually located along major rivers and near the trading posts. The security posts are staffed by Breeds and GroSec security robots, and among other things provide power and maintenance support to robots.



Common dress in the Borders tends toward trousers and tunics, usually in fairly bright colors and intricate patterns. A number of berries from desert plants are used for dyes, and the people in the Borders are, in general, more accomplished weavers than their brothers and sisters in the Settled Lands. Alchemists in the Borders also have rediscovered the secret of black powder, and it is made locally and sold both to the Subject Lands and the Outback. Primitive black powder weapons are the most common form of weapons encountered here.

Their language is clearly Anglic, but it is usually spoken with a noticeable accent, and experienced travellers soon learn to tell the difference between the accents of the people living along the Polar Sea, those living around the Sea of Halcyon and those living inland on the plains.

Outback

By statistical standards, the population density of the Outback is effectively zero. There are people there, but they are spread very thin. Most of the people living in the Outback are nomadic tribesmen, who live by tending herds of domesticated grazing animals similar to goats. Since surface vegetation is very sparse, the bands have to keep moving most of the time to find new grazing lands, and the small tribes seldom meet one another (as their ranges are separate and usually well-defined). When bands do meet at the edges of their ranging areas, it is usually cause for modest feasting and celebration. Like most nomadic cultures, there are strong taboos against marriage between members of the same band, so these meetings usually involve several days of courtships between the bands, followed by a number of new marriages. This cycle of isolation followed by celebration when others are encountered has produced a strong tradition of hospitality and sanctuary, which is again very common among desert nomadic tribes everywhere.

A substantial part of the human population of the Outback lives along the shores of the Polar Sea, where the weather is more moderate and there is more rainfall. Some of these

coastal dwellers are fishers, while others farm the river banks. Of all the people in the Outback, only those along the shores of the sea are not nomadic.

Robots used to occasionally patrol the Outback, but the growing success of resistance bands (see **page XX**) has led to their replacement by Breeds. Breed patrols conduct occasional sweeps of areas of the Outback, and lately have been particularly active in the Freedom Lake area in response to the growing level of modern armaments encountered there. Most of the bands are armed with a mix of black powder weapons purchased from the Borders, and locally manufactured bows, spears and other melee weapons.

Common dress in the Outback tends toward very loose, baggy trousers and tunics, usually made of homespun wool. Brightly colored festive clothing, highly prized and carefully preserved from meeting to meeting, is usually purchased from merchants who have brought it from the Borders.

The language spoken is heavily accented Anglic. The bands around Freedom Lake and Lake Defiance have begun speaking in an accent more reminiscent of standard Galanglic, and will not be easy for off-worlders to understand. Other tribes will still be intelligible for general concepts, but many unique nuances of meaning and emotion will be lost on strangers.

Animals

Common domesticated livestock on Promise include a goat-like animal called a *ramis*, raised for milk, meat, and wool, and a slow but powerful beast of burden called a *kurta*, both grazers. Among the more dangerous predators of the plains is a species of medium-sized chaser (averaging 50 kilos each) called *gaashken*, which travel in packs of a dozen or more animals. All of these animals are quadrupeds.

Encounters on Promise

When traveling across Promise, various encounters are possible. Derelict cities and other evidence of the Final War are fairly common. Human and Robot encounters, while perhaps less common, are potentially more interesting and dangerous.

The referee rolls 1D6 for each 700-kilometer hex traveled or once per day (if moving at a slower rate of speed) to determine the nature of the encounter. It is assumed that something of interest will be encountered in each hex or each day. In the Outback, referees may wish to arbitrarily make one-half to two-thirds of the encounters animals when travelling on the ground, due to the very low population density. The following brief descriptions will assist the referee in fleshing out these encounters. The chart is meant to be a guide, not a rigid limitation, and the referee should make each encounter different in some way. Players should never feel that the people they encounter are simply random entries on a table.

Encounter Descriptions

Animal: This is often the equivalent of no encounter, as it is usually just an animal sighting. If the characters are hunting, this encounter may mean game. It is also an opportunity to introduce unusual or interesting animal encounters, such as large predators.

Band: A band is a small group of characters usually organized for a specific purpose. It may consist of several family groups, but more often consists solely of males. A band may consist of one of the following specific encounters.

Breeds: A Breed patrol, either on a security sweep or looking for a specific resistance band. It consists of six to 20 or more armed Breeds, depending on the location and mission. Breed patrols are encountered almost exclusively in the Outback and the Borders. They are seldom used among the Subject Tribes. See page 55 for more details.

Brigands: A group of armed thieves, usually no more than a dozen or two and sometimes even fewer. They are usually armed with primitive weapons but occasionally will have one or more modern small arms. Brigands will sometimes pass themselves off as resistance fighters, and in many cases the distinction is unclear. Brigands can be found almost anywhere, although they are less common in the Subject Lands.

Fishers: One or more small boats manned by two to four fishers each. Fishers are encountered only on rivers and larger bodies of water. They are seldom armed (except with harpoons and marlin spikes, the equivalent of spears) and are not hostile.

Gypsies: Gypsies always travel in small bands of two or three dozen. As they are outlawed from the Subject Lands, they are seldom found there (although some Gypsy bands spend their entire time there, moving at night and hiding during the day). Most Gypsies are found in the Outback, and some bands are accompanied by Free Breeds (see Breeds description). Gypsies are not aggressively hostile, but are very suspicious and often difficult to approach. See page 58 for more details.

Hunters: A half dozen or more humans hunting for food, usually only lightly armed with primitive weapons. They are unlikely to be hostile to characters, but will be wary.

Resistance: A resistance group, either a small patrol of a half dozen or a large band of 100 or more. They are armed with a mix of primitive and modern weapons, with modern weapons more common close to Freedom Lake and primitive weapons more common elsewhere. Resistance bands are usually found only in the Outback, although they may occasionally be found in the Border Lands. See page 59 for more details.

Robots: A robot patrol, either on a security sweep or looking for a specific resistance band. It consists of from six to 12 security robots, depending on the location and mission. Robot patrols are encountered almost exclusively in

the Border Lands and the Subject Lands. They are seldom used in the Outback. See page 54 for more details.

Tribe: A large settlement or encampment of human families. Usually some of the adults are armed, although usually with only primitive weapons.

Merchant: A small group or caravan of merchants, usually carrying recovered technological relics from before the Collapse, but sometimes carrying more mundane trade goods, such as food, clothing, etc. This may be a group actually transporting technology, or the characters may happen upon locals excavating an abandoned city recovering equipment. Merchants are usually armed and may have a few modern weapons in addition to their more primitive ones.

Militia: A group of human auxiliaries recruited by the Sentient Council to maintain security in the Subject Lands. These are usually large groups of militia, either moving from one area to another or conducting a sweep. They are armed with primitive weapons and are likely to be both suspicious of and hostile to characters who do not have a good explanation for their presence.

RESISTANCE

The human resistance to the Rule of the Machines is a dynamic and growing force on Promise, one with which player characters will interact frequently.

Star City: Of the approximately 50,000 humans in the city, almost 1000 are active members of the resistance. Most of these are divided into three-person cells, and only one person in the cell knows anyone else in the organization. There are a number of larger "strike teams" of a dozen or so fighters, made up of resistance members who have proven their loyalty and reliability, but these are exceptional.

The Central Command of the resistance is located in Star City, and consists of the Skywatch Virus-infected computer (one of the members of the Sentient Council) and a small staff of perhaps a dozen key advisors and leaders. To direct the organization, Skywatch assumes the identity of an invented human called simply Number One. Only the dozen top leaders of the resistance and a handful of loyal robots infected with the Peacemaker strain of Virus know the truth. Despite the fact that Number One is actually a computer Virus, its loyalty is actually to the human resistance rather than the Council, and it is not setting up the resistance just to crush it. As a Peacemaker-strain Virus, it is working frantically to find a common ground for cooperation between humans and the minority of relatively sane sentient machines.

Central Command, with its access to the orbital communication relays of Skywatch, is able to communicate securely with the remote resistance bands by means of solar-powered satellite uplink receivers. It also operates a small network of roving technicians in the Outback, called Rangers, who keep the uplink receivers running.

Subject Lands: There is very little organized resistance activity in the Subject Lands. Although there is considerable fear and resentment of the Council, and no shortage of young firebrands willing to strike a blow, security is so tight and the human population so riddled with informers that all efforts to set up a widespread structure have been crushed.

As a result, the most important single activity of the scattered resistance members is "agitprop" activities, mostly consisting of nocturnal posting of flyers and handbills. These sometimes tell of a new outrage by the Council, either real (such as MedCom's Breed experiments) or imagined (a report that the processed food patties traded by the Council for goods are made from the bodies of captured slaves). All these posters urge the population to take no action yet, but "Remain ready to strike."

Borders: The resistance is gaining strength in the borders, although for now it is as much a social organization as an active group of fighters. There are few targets of genuine opportunity in the Borders, and most of the installations consist of heavily protected police posts, far too difficult to overcome with inexperienced guerrillas. There are no armed bands per se, but a few underground cells have hidden weapons. In addition, Central Command has planted a few downlink receivers with particularly reliable groups and can activate them if the situation requires it. These groups can fight if necessary, but their specialty is logistical support. They have assembled caches of fuel, food, medicine and ammunition in case the resistance can suddenly move into an area and begin operations.

Outback: In a sense, everyone in the Outback is a member of the resistance. The Outback is territory over which the Sentient Council does not have even a pretense of control, so the people who live there call themselves the Free Tribes, and rightly so. (But it is equally true that the Council's lack of control over the Outback stems more from a lack of interest than capability. There simply is very little of value in the Outback, and certainly not enough for the Council to expend scarce robots to control.)

While everyone may be part of the resistance to a greater or lesser degree, for most of them it is merely philosophical. Most people in the Outback have never heard of the human resistance, and some in remote parts of the planet have never seen a robot and do not believe they exist.

The actual hard core of the resistance in the Outback consists of the organized and armed bands linked to Central Command by satellite uplinks. The core bands of resistance fighters are clustered generally around Lake Defiance and Freedom Lake. Those closest to the lakes tend to have the best equipment, having the first pick of cargo brought in by the Coalition, Guild and free traders. The

LESLIE LANGERON

Langeron is the leader of the Black January Brigade, a resistance cell that operates in the Freedom Lake area. The Black January Brigade is a nomadic community of about 150 people, of whom perhaps 60 are actual combatants. The rest are too young or too old to fight, or are mothers nursing infant children. The band is well-armed with modern assault rifles and grenade launchers, and many of the fighters are Experienced NPCs. Langeron's band is one of the stronger resistance units, and although Langeron is ambitious, she is completely committed to Central Command.

Experienced NPC

Combat Assets: Slug Weapon (Slug Rifle), Armed Martial Arts (Small Blade), Unarmed Martial Arts

Other Assets: Leadership 14, Persuasion 13, Survival 12, Stealth 12

Motivation: *Club 9:* Langeron is a tough guerrilla fighter. She has seen many horrible things, and years of fighting absolutely merciless machines has trained her to regard violence as an effective and acceptable means of solving problems of almost any sort. The struggle against the machines has become her entire life. She has never known life without the machines, and has no real vision of what life might be like after victory, nor does she feel a need for such a vision. The struggle itself is sufficient.

Spade 7: Langeron does not think the isolated, feuding bands will ever accomplish much by themselves. The bands must be united under a single leader—herself—before they can make any real progress against the machines. She has so far been unable to convince "Central Command" (see page 00) of this, but she keeps trying. To the extent that the Coalition and the PCs can help her achieve this ambition, she will actively court them, and her perception of their utility in this respect will be the gauge of how enthusiastically and effectively she cooperates with the mission team.

bands communicate on a limited basis through the rangers. There are no more than 100 rangers total, and their main function is to repair and maintain the uplink receivers. They also keep the bands informed as to the activities and locations of others, so they have become an important link in maintaining cohesion and morale.

Aside from the above are bands who also have heard of the resistance, but whose principal means of livelihood consists of brigandage. These bands often style themselves as resistance fighters, and justify their thievery and extortion as enabling them to carry on "the struggle." In some cases, they actually do attack Breed patrols or "collaborators." The more active genuine resistance bands often spend so much energy on training and raids that their food production suffers, and they sometimes rely on forced "requisition" of foodstuffs from nonfighting bands. Given this blurring of activities, it is very difficult to separate brigands from freedom fighters, and for many bands it is more a question of degree than distinct type.

Beyond the core bands equipped with satellite uplinks and armed brigands is a broader group of bands who have heard of and consider themselves sympathetic to the resistance, but who are occupied primarily with survival. If persuaded by events or a charismatic leader, they might become more actively involved. They are often called on to furnish food to resistance raiding parties, and often their young men and women are recruited directly into fighting bands.

As the bands receive better and better armaments, a growing problem is one of leadership. Some of the more active brigands have become almost full-time resistance fighters, but do not pay any attention to Central Command (and they don't have satellite communicators anyway).

In some areas, groups are challenging the dominant position of the older resistance bands and are particularly anxious to get a piece of the trading rights around the lakes. Open fighting between bands, all but unknown a few years ago, is becoming more and more common.

GYPSIES

Although not in any way a part of the organized resistance movement commanded by Number One, the "Gypsies" of Promise have to be included here.

The Gypsies are psionically adept humans who generally live apart from the rest of society. Psionic powers are outlawed by the Sentient Council, and psions are ruthlessly persecuted in the Subject Lands and the Borders. As a result, virtually all Gypsies live in the Outback and practice the same nomadic life-style common to the other humans.

The Gypsies are the descendants of the members of a psionic institute on Promise. Following the Collapse, psions continued to be persecuted (some on Promise actually blamed them for the Collapse), and the survivors fled into the wilderness as their only chance of survival. The nomads of the Outback still are suspicious of them, and they are generally disliked. These feelings are stronger in the Borders, and in the Subject Lands parents frighten their children with stories of the Gypsies steeling children at night.

This antipathy by human society toward Gypsies is returned by them in full. Most Gypsies are suspicious of "Norms," as they call normal (nonpsionic) humans, and they particularly distrust any governmental or similar institution. As a result, they are generally friendlier with the brigands than they are with the more disciplined resistance bands, even though they have a stronger common interest with the resistance in defeating the Council.

Psionics is not a reliably inherited trait, so many of the Gypsy children are not psions, and these grow to adulthood as full members of the group, but seldom assume positions of leadership. Often they will leave the band to live with norms when they can find a band which will accept them. The Gypsies recruit new psions from other bands whenever they are able to test them, and many people who suspect they have latent psionic talent will go on a quest to find and join the Gypsies to receive training. (The recruiting of young psionically adept men and women is probably the origin of the stories of baby kidnappings.)

Appearance: Gypsies tend to wear the same style of clothing as other desert nomads, but in shades of grays, whites and subdued earth tones. They usually either allow their hair to grow very long or shave their heads altogether. If worn long, the hair is almost always tied back or braided. A style currently popular among Gypsy women is to gather all their hair up into a topknot ending in a long ponytail, or to shave all of the head except for a circle of hair two or three inches in diameter on the top of the head which is also wrapped in a topnot ending in a long ponytail, similar to a Cossack scalplock.

Free Breeds: A few psions have the ability to "cleanse" computers of Virus (although this seldom leaves the computer functional afterward), through a combination of Computer Empathy and Telephysics. This enables them to free captured Breeds from their silicon second brain.

These Free Breeds remain outcasts in human society, where they are still considered abominations, so they usually chose to accompany the psions. Bands with cleansers usually have half a dozen or more Free Breeds with them.

STEELDANCER

The current leader of the Mondaroo Gypsies, Steeldancer is also an accomplished psion. Her unusual talents make her particularly effective against robots, and she is one of the few individuals honored by the Sentient Council with a price on her head. Steeldancer's ability to psionically disrupt computers has enabled her to free a large number of Breeds from their Virus-controlled silicon "second brains" (another reason the Sentient Council wants her dealt with), and she is constantly accompanied by three absolutely dedicated Free Breed bodyguards.

Experienced NPC

Combat Assets: Armed Melee Combat

Other Assets: Computer Empathy 15, Telephysics (Telekinesis) 13, Willpower 9, Leader 12
